Summary In view of the similarity in chemical structure of the available 5HT₃-receptor antagonists it is assumed, whilst these agents all act at the same receptor, that failure to one agent would predict subsequent failure to all 5HT₃-receptor antagonists. We conducted a randomized double blind trial of granisetron 3 mg plus dexamethasone 10 mg versus continued treatment with ondansetron 8 mg plus dexamethasone 10 mg in patients with protection failure on ondansetron 8 mg plus dexamethasone 10 mg during the first 24 hours following highly emetogenic chemotherapy. Of 40 eligible patients, 21 received ondansetron + dexamethasone and 19 received granisetron + dexamethasone. We found a significant benefit from crossing-over to granisetron after failure on ondansetron. Of the 19 patients who crossed over to granisetron, 9 patients obtained complete protection, whereas this was observed in 1 of the 21 patients continuing ondansetron, P = 0.005. These results indicate that there is no complete cross-resistance between 5HT₃-receptor antagonists, and that patients who have acute protection failure on one 5HT₃-receptor antagonist should be offered cross-over to another 5HT₃-receptor antagonist.

PATIENTS AND METHODS

Eligibility required protection failure (defined as ≥ 2 vomits, severe nausea (no significant intake possible) or nausea > 4 hours) within 24 hours after single day cisplatin ≥ 50 mg m⁻² or cyclophosphamide ≥ 500 mg m⁻² based chemotherapy, on antiemetic prophylaxis with ondansetron 8 mg i.v. and dexamethasone 10 mg i.v. Eligibility also required that there were no planned dose attenuations, no use of other antiemetic agents, benzodiazepines, or opiates, and no emesis in the 24 hours preceding the study cycle.

After informed consent patients were randomized in a double blind fashion to granisetron 3 mg i.v. plus dexamethasone 10 mg i.v. or continued treatment with ondansetron 8 mg i.v. plus dexamethasone 10 mg i.v. The medication was prepared in blinded 50 ml saline bags by the pharmacist.

Results were documented by the patient on diary cards:

- Complete protection (CP) was defined as no vomiting and no or mild nausea.
- Partial protection (PP) was defined as 0–1 vomits, and/or moderate nausea during a maximum of 4 hours.
- Failure (F) was defined as ≥ 2 vomits, or severe nausea (no significant intake possible), or nausea lasting more than 4 hours.
RESULTS
A total of 45 patients were randomized. 5 patients were excluded at the study cycle for the following reasons; nausea prior to the chemotherapy (2), chemotherapy dose reductions (2), other antiemetics (1). Of 40 eligible patients, 21 received ondansetron plus dexamethasone, and 19 crossed-over to granisetron plus dexamethasone. Patients were well balanced for age, sex, type and dose of chemotherapy and number of previous cycles (Table 1).

We found a significant benefit from crossing-over to granisetron after failure to ondansetron (Table 2). Of the 19 patients who crossed-over to granisetron, 9 patients obtained complete protection (CP), whereas this was observed in 1 of 21 patients continuing ondansetron, $P = 0.005$ (Fisher exact test). The $P$ value of a test for trend with ordered categories ($\chi^2$ trend) was < 0.005. Successful cross-over was observed both in patients receiving cisplatin, and in patients receiving cyclophosphamide-based chemotherapy, but the numbers in the subsets were too small to perform meaningful subanalyses.

DISCUSSION
Several large well-designed randomized studies between ondansetron and granisetron have demonstrated equivalent antiemetic efficacy (Ruff et al, 1994; Navari et al, 1995; Stewart et al, 1995; Perez et al, 1998). Reviewing the more recently conducted randomized trials of a sample size that justifies to draw such conclusion, there appears no therapeutical difference between ondansetron doses ranging from 8 mg, given as a single dose before the start of the chemotherapy to 32 mg administered during the first 24 hours (Ruff et al, 1994; Italian Group of Antiemetic Research, 1995; Gandara et al, 1998). The same applies for granisetron single dosages of 1 and 3 mg (Navari et al, 1994, 1995; Morrow et al, 1995; Perez et al, 1997; Gralla, 1998; Martoni et al, 1998). In addition, there are no data to support the use of higher doses of the same 5HT$_3$-receptor antagonists in patients failing the recommended dosage (Gandara et al, 1998).

Hence, it is unlikely that the high rate of successful complete protection by granisetron after failure to ondansetron in the present study can be explained by better dose-effectiveness of granisetron 3 mg as compared with ondansetron 8 mg. The results in our study indicate that there is no complete cross-resistance between these two 5HT$_3$-receptor antagonists, at least not in the sequence ondansetron failure, followed by cross-over to granisetron. These findings lend support to our previous observation of successful cross-over between 5HT$_3$ receptor antagonists, indicating that there is no complete cross-resistance between these agents (de Boer et al, 1995). In this pilot study, 5 of 14 patients who had emesis protection failure on tropisetron obtained complete protection after cross-over to ondansetron.

Therefore, we conclude that there is no cross-resistance between 5HT$_3$-receptor antagonists and that patients who have acute protection failure on one 5HT$_3$-receptor antagonist should be offered cross-over to another 5HT$_3$-receptor antagonist.
