0. Introduction

This article is a continuation of our work \([\text{KN2}]\) which concerned two known functors. The definition of one of these two functors belongs to V. Drinfeld \([\text{D2}]\). Let \(A\) be the degenerate affine Hecke algebra corresponding to the general linear group \(GL_N\) over a non-Archimedean local field. This is an associative algebra over the field \(\mathbb{C}\) which contains the symmetric group ring \(\mathbb{C}\Sigma_N\) as a subalgebra. Let \(Y(\mathfrak{gl}_n)\) be the Yangian of the general linear Lie algebra \(\mathfrak{gl}_n\). This is a deformation of the universal enveloping algebra of the polynomial current Lie algebra \(\mathfrak{gl}_n\) in the class of Hopf algebras \([\text{D1}]\). It contains the universal enveloping algebra \(U(\mathfrak{gl}_n)\) as a subalgebra. There is also a homomorphism of associative algebras \(Y(\mathfrak{gl}_n) \rightarrow U(\mathfrak{gl}_n)\) identical on the subalgebra \(U(\mathfrak{gl}_n) \subset Y(\mathfrak{gl}_n)\). In \([\text{D2}]\) for any \(A_N\)-module \(M\), an action of the algebra \(Y(\mathfrak{gl}_n)\) was defined on the vector space \((M \otimes (\mathbb{C}^n)^{\otimes N})^{\Sigma_N}\) of the diagonal skew \(\Sigma_N\)-invariants in the tensor product of the vector spaces \(M\) and \((\mathbb{C}^n)^{\otimes N}\). Thus one gets a functor from the category of all \(A_N\)-modules to the category of \(Y(\mathfrak{gl}_n)\)-modules, the Drinfeld functor.

In \([\text{KN1}]\) we studied the composition of the Drinfeld functor with another functor, introduced by I. Cherednik [C]. This second functor was also studied by T. Arakawa, T. Suzuki and A. Tsuchiya [A, AS, AST]. For any module \(U\) over the Lie algebra \(\mathfrak{gl}_l\), an action of the algebra \(A_N\) can be defined on the tensor product \(U \otimes (\mathbb{C}^l)^{\otimes N}\) of \(\mathfrak{gl}_l\)-modules. This action of \(A_N\) commutes with the diagonal action of \(\mathfrak{gl}_l\) on the tensor product. Thus one gets a functor from the category of all \(A_N\)-modules to the category of \(Y(\mathfrak{gl}_l)\)-modules, the Cherednik functor. By applying the Drinfeld functor to the \(A_N\)-module \(M = U \otimes (\mathbb{C}^l)^{\otimes N}\), one turns to an \(Y(\mathfrak{gl}_n)\)-module the vector space

\[
(U \otimes (\mathbb{C}^l)^{\otimes N} \otimes (\mathbb{C}^n)^{\otimes N})^{\Sigma_N} = U \otimes \Lambda^N(\mathbb{C}^l \otimes \mathbb{C}^n).
\]

The action of the associative algebra \(Y(\mathfrak{gl}_n)\) on this vector space commutes with the action of \(\mathfrak{gl}_l\). By taking the direct sum of these \(Y(\mathfrak{gl}_n)\)-modules over \(N = 0, 1, \ldots, n\) we turn to an \(Y(\mathfrak{gl}_n)\)-module the space \(U \otimes \Lambda(\mathbb{C}^l \otimes \mathbb{C}^n)\). It is also a \(\mathfrak{gl}_l\)-module; denote this bimodule by \(E_l(U)\). We identify the exterior algebra \(\Lambda(\mathbb{C}^l \otimes \mathbb{C}^n)\) with the Grassmann algebra \(\mathcal{G}(\mathbb{C}^l \otimes \mathbb{C}^n)\), and denote by \(\mathcal{GD}(\mathbb{C}^l \otimes \mathbb{C}^n)\) the ring of \(\mathbb{C}\)-endomorphisms of \(\mathcal{G}(\mathbb{C}^l \otimes \mathbb{C}^n)\). The action of the Yangian \(Y(\mathfrak{gl}_n)\) on its module \(E_l(U)\) is then determined by a homomorphism \(\alpha_l : Y(\mathfrak{gl}_n) \rightarrow U(\mathfrak{gl}_l) \otimes \mathcal{GD}(\mathbb{C}^l \otimes \mathbb{C}^n)\), see Proposition 1.2 below.
Now let $f_m$ be either the orthogonal Lie algebra $\mathfrak{so}_{2m}$ or the symplectic Lie algebra $\mathfrak{sp}_{2m}$. The first objective of the present article is to define analogues of the functor $\mathcal{E}_l$ and of the homomorphism $\alpha_l$ for the Lie algebra $f_m$ instead of $\mathfrak{gl}_l$. The role of the Yangian $Y(\mathfrak{gl}_n)$ is played here by the twisted Yangian $Y(\mathfrak{g}_n)$, which is a right coideal subalgebra of the Hopf algebra $Y(\mathfrak{gl}_n)$. Here $\mathfrak{g}_n$ is a Lie subalgebra of $\mathfrak{gl}_n$, orthogonal in the case $f_m = \mathfrak{so}_{2m}$ and symplectic in the case $f_m = \mathfrak{sp}_{2m}$; in the latter case $n$ has to be even. Let the superscript ‘$\prime$’ indicate the transposition in $\mathfrak{gl}_n$ relative to the bilinear form on $\mathbb{C}^n$ preserved by the subalgebra $\mathfrak{g}_n \subset \mathfrak{gl}_n$, so that $\mathfrak{g}_n = \{ A \in \mathfrak{gl}_n \mid A' = -A \}$. As an associative algebra, $Y(\mathfrak{g}_n)$ is a deformation of the universal enveloping algebra of the twisted polynomial current Lie algebra

$$\{ A(u) \in \mathfrak{gl}_n[u] \mid A'(u) = -A(-u) \}.$$

Twisted Yangians were introduced by G. Olshanski [O2], their structure has been studied in [MNO]. In Section 2 of the present article we introduce a homomorphism $Y(\mathfrak{g}_n) \to U(f_m) \otimes \mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)$, see our Propositions 2.3 and 2.4. The image of $Y(\mathfrak{g}_n)$ under this homomorphism commutes with the image of the algebra $U(f_m)$ under its diagonal embedding (2.7) to the tensor product $U(f_m) \otimes \mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)$; here we use the homomorphism $\zeta_n : U(f_m) \to \mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)$ defined by (2.6). The twisted Yangian $Y(\mathfrak{g}_n)$ contains the universal enveloping algebra $U(\mathfrak{g}_n)$ as a subalgebra. There is also a homomorphism $\pi_n : Y(\mathfrak{g}_n) \to U(\mathfrak{g}_n)$ identical on the subalgebra $U(\mathfrak{g}_n) \subset Y(\mathfrak{g}_n)$. Our results extend the classical theorem [H] stating that the image of $U(f_m)$ in $\mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)$ under the homomorphism $\zeta_n$ consists of all $G_n$-invariant elements. Here $G_n$ is either the orthogonal or the symplectic group, so that $\mathfrak{g}_n$ is its Lie algebra; the group $G_n$ acts on $\mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)$ via its natural action on $\mathbb{C}^n$.

In the present article we prefer to work with a certain central extension $X(\mathfrak{g}_n)$ of the algebra $Y(\mathfrak{g}_n)$, called the extended twisted Yangian. Central elements $O^{(1)}, O^{(2)}, \ldots$ of the algebra $X(\mathfrak{g}_n)$ generating the kernel of the canonical homomorphism $X(\mathfrak{g}_n) \to Y(\mathfrak{g}_n)$ are given in Section 1, together with the definitions of $X(\mathfrak{g}_n)$ and $Y(\mathfrak{g}_n)$. There is also a homomorphism $X(\mathfrak{g}_n) \to X(\mathfrak{g}_n) \otimes Y(\mathfrak{g}_n)$. Using it, the tensor product of any modules over the algebras $X(\mathfrak{g}_n)$ and $Y(\mathfrak{g}_n)$ becomes another module over $X(\mathfrak{g}_n)$. Moreover, this homomorphism is a coaction of the Hopf algebra $Y(\mathfrak{gl}_n)$ on the algebra $X(\mathfrak{g}_n)$. We define a homomorphism $\beta_m : X(\mathfrak{g}_n) \to U(f_m) \otimes \mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)$ which is our analogue of the homomorphism $\alpha_l$, see Proposition 2.3. The image of $X(\mathfrak{g}_n)$ under $\beta_m$ commutes with the image of the algebra $U(f_m)$ under its embedding (2.7) to $U(f_m) \otimes \mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)$. The reason why we work with $X(\mathfrak{g}_n)$ rather than with $Y(\mathfrak{g}_n)$ is explained in Section 2.

The generators of the algebra $X(\mathfrak{g}_n)$ appear as coefficients of certain series $S_{ij}(u)$ in the variable $u$ where $i, j = 1, \ldots, n$. We define the homomorphism $\beta_m$ by applying it to the coefficients, and by giving the resulting series $\beta_m(S_{ij}(u))$ with coefficients in $U(f_m) \otimes \mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)$ explicitly. Then we define another homomorphism

$$\tilde{\beta}_m : X(\mathfrak{g}_n) \to U(f_m) \otimes \mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)$$

which factors through the canonical homomorphism $X(\mathfrak{g}_n) \to Y(\mathfrak{g}_n)$. Thus we obtain the homomorphism $Y(\mathfrak{g}_n) \to U(f_m) \otimes \mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)$ mentioned above. Every series $\tilde{\beta}_m(S_{ij}(u))$ is the product of $\beta_m(S_{ij}(u))$ with a certain series with coefficients from $Z(f_m) \otimes 1$, where $Z(f_m)$ is the centre of the algebra $U(f_m)$. 

The defining relations of the algebra $X(\mathfrak{g}_n)$ can be written as the reflection equation (1.15) on the $n \times n$ matrix $S(u)$ whose $i,j$ entry is the series $S_{ij}(u)$. This terminology was introduced by physicists; see for instance [KS] and references therein.

Now let $V$ be any $f_m$-module. Using the homomorphism $\beta_m$, we turn the vector space $V \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n)$ into a bimodule over $f_m$ and $X(\mathfrak{g}_n)$. We denote this bimodule by $\mathcal{F}_m(V)$. The functor $\mathcal{F}_m$ is our analogue of the functor $\mathcal{E}_l$ for $f_m$ instead of $\mathfrak{gl}_l$. When $m = 0$, we set $\mathcal{F}_0(V) = \mathbb{C}$ so that $\beta_0$ is the composition of the canonical homomorphism $X(\mathfrak{g}_n) \to Y(\mathfrak{g}_n)$ with the restriction of the counit homomorphism $Y(\mathfrak{g}_l) \to \mathbb{C}$ to $Y(\mathfrak{g}_n)$.

Here we show that the functor $\mathcal{F}_m$ shares the three fundamental properties of the functor $\mathcal{E}_l$ considered in [KN2]. The first of these properties of $\mathcal{E}_l$ concerns parabolic induction from the direct sum of Lie algebras $\mathfrak{gl}_m \oplus \mathfrak{gl}_l$ to $\mathfrak{gl}_{m+l}$. Let $p$ be the maximal parabolic subalgebra of $\mathfrak{gl}_{m+l}$ containing the direct sum $\mathfrak{gl}_m \oplus \mathfrak{gl}_l$. Let $q \subset \mathfrak{gl}_{m+l}$ be the Abelian subalgebra with $\mathfrak{gl}_{m+l} = q \oplus p$. For any $\mathfrak{gl}_m$-module $W$ let $W \otimes U$ be the $\mathfrak{gl}_{m+l}$-module parabolically induced from the $\mathfrak{gl}_m \oplus \mathfrak{gl}_l$-module $W \otimes U$. This is a module induced from the subalgebra $p$. Consider the space $\mathcal{E}_{m+l}(W \otimes U)_q$ of $q$-coinvariants of the $\mathfrak{gl}_{m+l}$-module $\mathcal{E}_{m+l}(W \otimes U)$. This space is an $Y(\mathfrak{gl}_n)$-module, which also inherits the action of the Lie algebra $\mathfrak{gl}_m \oplus \mathfrak{gl}_l$. The additive group $\mathbb{C}$ acts on the Hopf algebra $Y(\mathfrak{gl}_n)$ by automorphisms. Let $\mathcal{E}_l^{-z}(U)$ be the $Y(\mathfrak{gl}_n)$-module obtained from $\mathcal{E}_l(U)$ by pulling it back through the automorphism of $Y(\mathfrak{gl}_n)$ corresponding to $z \in \mathbb{C}$. The automorphism itself is denoted by $\tau_z$, see (1.2). Thus the underlying vector space of the $Y(\mathfrak{gl}_n)$-module $\mathcal{E}_l^{-z}(U)$ is $U \otimes \mathcal{G}(\mathbb{C}^l \otimes \mathbb{C}^n)$, whence the action of $Y(\mathfrak{gl}_n)$ is defined by the composition of two homomorphisms,

$$Y(\mathfrak{gl}_n) \xrightarrow{\tau_z} Y(\mathfrak{gl}_n) \xrightarrow{\alpha_l} U(\mathfrak{gl}_l) \otimes \mathcal{G}D(\mathbb{C}^l \otimes \mathbb{C}^n). \quad (0.1)$$

The target algebra here acts on $U \otimes \mathcal{G}(\mathbb{C}^l \otimes \mathbb{C}^n)$ by definition. As a $\mathfrak{gl}_l$-module $\mathcal{E}_l^{-z}(U)$ coincides with $\mathcal{E}_l(U)$. In [KN2] we proved that the bimodule $\mathcal{E}_{m+l}(W \otimes U)_q$ of $Y(\mathfrak{gl}_n)$ and $\mathfrak{gl}_n \oplus \mathfrak{gl}_l$ is equivalent to $\mathcal{E}_m(W) \otimes \mathcal{E}_{m+l}^z(U)$ . We use the comultiplication on $Y(\mathfrak{gl}_n)$.

Our Theorem 3.1 is an analogue of this comultiplicative property of $\mathcal{E}_l$. Take the maximal parabolic subalgebra of the Lie algebra $f_{m+l}$ containing the direct sum $f_m \oplus \mathfrak{gl}_l$; we do not exclude the case $m = 0$ here. Using that subalgebra, determine the $f_{m+l}$-module $V \otimes U$ parabolically induced from the $f_m \oplus \mathfrak{gl}_l$-module $V \otimes U$. Consider the space of coinvariants of the $f_{m+l}$-module $\mathcal{F}_{m+l}(V \otimes U)$ relative to the nilpotent subalgebra of $f_{m+l}$ complementary to our parabolic subalgebra. This space is a bimodule over $f_m \oplus \mathfrak{gl}_l$ and $X(\mathfrak{g}_n)$. We prove that this bimodule is essentially equivalent to the tensor product $\mathcal{F}_m(V) \otimes \mathcal{E}_l^z(U)$ with $z = m - \frac{1}{2}$ for $f_m = \mathfrak{so}_{2m}$, and $z = m + \frac{1}{2}$ for $f_m = \mathfrak{sp}_{2m}$. More precisely, the underlying vector space of the $X(\mathfrak{g}_n)$-module $\mathcal{F}_m(V) \otimes \mathcal{E}_l^z(U)$ is

$$V \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n) \otimes U \otimes \mathcal{G}(\mathbb{C}^l \otimes \mathbb{C}^n), \quad (0.2)$$

whereon the action of $X(\mathfrak{g}_n)$ is defined by the composition of two homomorphisms,

$$X(\mathfrak{g}_n) \to X(\mathfrak{g}_n) \otimes Y(\mathfrak{gl}_n) \to U(f_m) \otimes \mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n) \otimes U(\mathfrak{gl}_l) \otimes \mathcal{G}D(\mathbb{C}^l \otimes \mathbb{C}^n).$$

Here the first homomorphism is the coaction $Y(\mathfrak{gl}_n)$ on $X(\mathfrak{g}_n)$, while the second one is the tensor product of the homomorphisms $\beta_m : X(\mathfrak{g}_n) \to U(f_m) \otimes \mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)$ and

$$\alpha_l \tau_{-z} : Y(\mathfrak{gl}_n) \to U(\mathfrak{gl}_l) \otimes \mathcal{G}D(\mathbb{C}^l \otimes \mathbb{C}^n);$$
Theorem 3.1 describes the first fundamental property of the functor $X(g_n)$ see (0.1). By multiplying the image of $S_{ij}(u) \in X(g_n)[[u^{-1}]]$ under this composition by a certain series with the coefficients from the subalgebra

$$1 \otimes 1 \otimes Z(gl_l) \otimes 1 \subset U(f_m) \otimes GD(C^n \otimes C^n) \otimes U(gl_l) \otimes GD(C^l \otimes C^n),$$

we get another homomorphism $X(g_n) \to U(gl_l) \otimes GD(C^l \otimes C^n)$. The latter homomorphism defines another action of $X(g_n)$ on the vector space (0.2). Theorem 3.1 states that this action is equivalent to the action of $X(g_n)$ on the space of coinvariants of $F_{m+1}(V \otimes U)$. Moreover, the actions of the direct summands of $U(gl_l)$ on $F_{m+1}(V) \otimes E(z)(U)$ and on the space of coinvariants of $F_{m+1}(V \otimes U)$ are also equivalent, while the actions of the direct summands $gl_l$ differ only by the automorphism (3.6) of the Lie algebra $gl_l$. Hence Theorem 3.1 describes the first fundamental property of the functor $F_m$.

Let us now discuss the second fundamental property of $F_m$. In [TV] V. Tarasov and A. Varchenko established a correspondence between canonical intertwining operators on $l$-fold tensor products of certain $Y(gl_n)$-modules, and the extremal cocycle on the Weyl group $S_l$ of the reductive Lie algebra $gl_1$ defined by D. Zhelobenko [Z]. In [TV] each of the tensor factors is obtained from one of $gl_n$-modules $S^n(C^n)$ by pulling back through the homomorphism $Y(gl_n) \to U(gl_l)$ and then back through one of the automorphisms $\tau_z : Y(gl_n) \to Y(gl_n)$. Here $S^n(C^n)$ is the $N$-th symmetric power of the vector space $C^n$, while the homomorphism $Y(gl_n) \to U(gl_n)$ is defined by (1.4). In [KN1] we gave a representation theoretic explanation of that correspondence from [TV], by employing the theory of Mickelsson algebras [M1, M2] as developed in [KO].

For any $N \in \{1, \ldots, n\}$ and any $z \in \mathbb{C}$ we denote by $P_z^N$ the $Y(gl_n)$-module obtained by pulling back the action of $U(gl_n)$ on the subspace of $\mathcal{G}(C^n)$ of degree $N$ through the homomorphism $Y(gl_n) \to U(gl_n)$ and then through the automorphism $\tau_{-z}$ of $Y(gl_n)$. The action of the algebra $Y(gl_n)$ on $P_z^N$ is defined by the composition of homomorphisms

$$Y(gl_n) \xrightarrow{\tau_{-z}} Y(gl_n) \to U(gl_n) \to GD(C^n).$$

Here the second homomorphism is the one defined by (1.4), while the algebra $GD(C^n)$ acts on $\mathcal{G}(C^n)$ naturally. Using the functor $\mathcal{E}_l$, in [KN2] we established a correspondence between intertwining operators on the $l$-fold tensor products of modules of the form $P_z^N$, and the same extremal cocycle on $S_l$ as considered in [KN1]. This is an “antisymmetric” version of the correspondence first established in [TV]. The parameters $z$ corresponding to the $l$ tensor factors are in general position, that is their differences do not belong to $\mathbb{Z}$. Then each of the tensor products is irreducible as $Y(gl_n)$-module [NT]. Hence the intertwining operators between them are unique up to multipliers from $\mathbb{C}$.

In the present article we show that the functor $F_m$ plays a role similar to that of $\mathcal{E}_l$, when the Lie algebra $gl_l$ is replaced by $f_m$. Namely, we establish a correspondence between intertwining operators of certain $X(g_n)$-modules, and the extremal cocycle on the hyperoctahedral group $H_m$ corresponding to the reductive Lie algebra $f_m$. Here $H_m$ is regarded as the Weyl group of $f_m = sp_{2m}$, and as an extension of the Weyl group of $f_m = so_{2m}$ by a Dynkin diagram automorphism. In both cases, the definition of the extremal cocycle is essentially due to D. Zhelobenko [Z]. However, the original extremal cocycle has been defined on the Weyl group of $f_m$, which in the case $f_m = so_{2m}$ is only a subgroup of $H_m$ of index 2. An extension of the original definition to the whole group $H_m$ was given in [KN3]. All necessary details on the extremal cocycle corresponding to $f_m$ are also reviewed in Section 4 of the present article.
The twisted Yangian $Y(\mathfrak{g}_n)$ is determined by a distinguished involutive automorphism (1.11) of the algebra $Y(\mathfrak{gl}_n)$. The automorphism (1.11) corresponds to the automorphism

$$A(u) \mapsto -A'(-u)$$

of the Lie algebra $\mathfrak{gl}_n[u]$, when the algebra $Y(\mathfrak{gl}_n)$ is regarded as a deformation of the universal enveloping algebra of $\mathfrak{gl}_n[u]$. By pulling the $Y(\mathfrak{gl}_n)$-module $P_z^N$ back through the automorphism (1.11) we get another $Y(\mathfrak{gl}_n)$-module, which we denote by $P_z^{-N}$. The underlying vector space of $P_z^{-N}$ consists of elements of $\mathcal{G}(\mathbb{C}^n)$ of degree $N$, whereon the action of $Y(\mathfrak{gl}_n)$ is defined by the composition of four homomorphisms

$$Y(\mathfrak{gl}_n) \rightarrow Y(\mathfrak{gl}_n) \rightarrow Y(\mathfrak{gl}_n) \rightarrow U(\mathfrak{gl}_n) \rightarrow \mathcal{G}\mathcal{D}(\mathbb{C}^n).$$

Here the first map is the automorphism (1.11), the other three are the same as in (0.3).

Now take any $\nu_1, \ldots, \nu_m \in \{1, \ldots, n\}$ and any $z_1, \ldots, z_m \in \mathbb{C}$ such that $z_a - z_b \notin \mathbb{Z}$ and $z_a + z_b \notin \mathbb{Z}$ when $a \neq b$. In the case $\mathfrak{f}_m = \mathfrak{sp}_{2m}$ we also assume that $2z_a \notin \mathbb{Z}$ for any $a$. The hyperoctahedral group $\mathfrak{H}_m$ can be realized as the group of all permutations $\sigma$ of $-m, \ldots, -1, 1, \ldots, m$ such that $\sigma(-c) = -\sigma(c)$ for any $c$. In Section 5 of the present article, we show how the value of the extremal cocycle for the Lie algebra $\mathfrak{f}_m$ at an element $\sigma \in \mathfrak{H}_m$ determines an intertwining operator of $X(\mathfrak{g}_n)$-modules

$$P_{\nu_m} \otimes \cdots \otimes P_{\nu_1} \rightarrow P_{\tilde{\nu}_m} \otimes \cdots \otimes P_{\tilde{\nu}_1}$$

(0.4)

where

$$\tilde{\nu}_a = \nu_{|\sigma^{-1}(a)|}, \quad \tilde{z}_a = z_{|\sigma^{-1}(a)|} \quad \text{and} \quad \delta_a = \text{sign} \sigma^{-1}(a)$$

(0.5)

for each $a = 1, \ldots, m$. The tensor products in (0.4) are those of $Y(\mathfrak{gl}_n)$-modules. By restricting both tensor products to the subalgebra $Y(\mathfrak{g}_n) \subset Y(\mathfrak{gl}_n)$ and by pulling the restrictions back through the canonical homomorphism $X(\mathfrak{g}_n) \rightarrow Y(\mathfrak{g}_n)$, both tensor products in (0.4) become $X(\mathfrak{g}_n)$-modules. Thus the actions of the algebra $X(\mathfrak{g}_n)$ on both tensor products in (0.4) are obtained by using the composition

$$X(\mathfrak{g}_n) \rightarrow Y(\mathfrak{g}_n) \rightarrow Y(\mathfrak{gl}_n) \rightarrow Y(\mathfrak{gl}_n)^{\otimes n}.$$
assignments (1.17) define an automorphism of the algebra $X(g_n)$. Up to pulling it back through such an automorphism, the source $X(g_n)$-module in (0.4) arises as the space of $n$-coinvariants of weight $\lambda$ for the $f_m$-module $F_m(M_\mu)$, where $M_\mu$ is the Verma module over $f_m$ with the highest vector of weight $\mu$ annihilated by the action of the subalgebra $n' \subset f_m$. The weights $\lambda$ and $\mu$ relative to the Cartan subalgebra $\mathfrak{h}$ are determined here by the parameters $\nu_1, \ldots, \nu_m$ and $z_1, \ldots, z_m$ from (0.4). We denote the space of $n$-coinvariants of weight $\lambda$ by $F_m(M_\mu)^{\lambda}_{n'}$. The algebra $X(g_n)$ acts on the latter space, because the action of $X(g_n)$ on $F_m(M_\mu)$ commutes with that of $f_m$. We prove that the above defined action of the algebra $X(g_n)$ on the source tensor product in (0.4) is equivalent to the action on the vector space of $F_m(M_\mu)^{\lambda}_{n'}$, defined by the composition
\[ X(g_n) \to X(g_n) \to \text{End}(F_m(M_\mu)). \] (0.6)

Here the first map is the automorphism (1.17) where $f(u)^{-1}$ equals the product (5.24). The second map here is the defining homomorphism of the $X(g_n)$-module $F_m(M_\mu)$.

To get the target $X(g_n)$-module in (0.4), we generalize our definition of the functor $F_m$. In the beginning of Section 5, for any sequence $\delta = (\delta_1, \ldots, \delta_m)$ of $m$ elements of the set $\{1, -1\}$ we define a functor $F_\delta$, with the same source and target categories as the functor $F_m$ has. Moreover, for any $f_m$-module $V$ the underlying vector spaces of the bimodules $F_\delta(V)$ and $F_m(V)$ are the same, that is $V \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n)$. The actions of $f_m$ and $X(g_n)$ on $F_\delta(V)$ are obtained by pushing forward the defining homomorphisms
\[ \zeta_n : U(f_m) \to \mathcal{G}\mathcal{D}(\mathbb{C}^m \otimes \mathbb{C}^n) \quad \text{and} \quad \beta_m : X(g_n) \to U(f_m) \otimes \mathcal{G}\mathcal{D}(\mathbb{C}^m \otimes \mathbb{C}^n) \]
through a certain automorphism $\varpi$ of the ring $\mathcal{G}\mathcal{D}(\mathbb{C}^m \otimes \mathbb{C}^n)$ depending on $\delta$. Namely, the automorphism $\varpi$ is defined by the assignments (5.1). Thus to define the functor $F_\delta$, we use the compositions $\varpi \zeta_n$ and $(1 \otimes \varpi) \beta_m$ instead of the homomorphisms $\zeta_n$ and $\beta_m$ respectively. In particular, we have $F_\delta(V) = F_m(V)$ for the sequence $\delta = (1, \ldots, 1)$.

Up to pulling it back through an automorphism of the form (1.17), the target $X(g_n)$-module in (0.4) arises as the space of $n$-coinvariants of weight $\sigma \circ \lambda$ for the $f_m$-module $F_\delta(M_{\sigma \circ \mu})$. The sequence $\delta = (\delta_1, \ldots, \delta_m)$ is as defined in (0.5), and the symbol $\circ$ here indicates the shifted action of the group $\mathfrak{S}_m$ on the weights of $\mathfrak{h}$. Our Proposition 5.4 states that action of the algebra $X(g_n)$ on the target tensor product in (0.4) is equivalent to the action on the vector space of $F_\delta(M_{\sigma \circ \mu})^{\sigma \circ \lambda}_{n'}$, defined by the composition
\[ X(g_n) \to X(g_n) \to \text{End}(F_m(M_{\sigma \circ \mu})). \] (0.7)

Here the first map is the automorphism (1.17) where $f(u)^{-1}$ equals the product (5.24). The second map here is the defining homomorphism of the $X(g_n)$-module $F_m(M_{\sigma \circ \mu})$.

In Section 5 we show that value of the extremal cocycle for the Lie algebra $f_m$ at the element $\sigma \in \mathfrak{S}_m$ determines an intertwining operator of $X(g_n)$-modules
\[ F_m(M_\mu)^{\lambda}_{n'} \to F_\delta(M_{\sigma \circ \mu})^{\sigma \circ \lambda}_{n'}. \] (0.8)

The product (5.24) does not depend on the element $\sigma \in \mathfrak{S}_m$, so that the automorphisms (1.17) of the algebra $X(g_n)$ in (0.6) and (0.7) are the same. Hence by replacing the source and the target $X(g_n)$-modules by their equivalent modules, we obtain our intertwining operator (0.4). The role played by the functor $F_m$ in this construction of the operator (0.4) is the second fundamental property of that functor.
The third fundamental property of the functor $E_l$ considered in [KN2] is its connection with the centralizer construction of the Yangian $Y(gl_n)$ proposed by G. Olshanski [O1]. For any two irreducible polynomial modules $U$ and $U'$ over the Lie algebra $gl_l$, the results of [O1] provide an action of $Y(gl_n)$ on the vector space

$$\text{Hom}_{gl_l}(U', U \otimes G(\mathbb{C}^l \otimes \mathbb{C}^n)).$$

(0.9)

Moreover, this action is irreducible. In [KN2] we proved that the same action of $Y(gl_n)$ on the vector space (0.9) is obtained when the target $gl_l$-module $U \otimes G(\mathbb{C}^l \otimes \mathbb{C}^n)$ in (0.9) is regarded as the bimodule $E_l(U)$ over $Y(gl_n)$ and $gl_l$.

There is a centralizer construction of $Y(gl_n)$ again due to G. Olshanski [O2], see also [MO] and Section 6 here. That construction served as a motivation for introducing the twisted Yangians. For any irreducible finite-dimensional modules $V$ and $V'$ of the Lie algebra $f_m$, the results of [O2] provide an action of the algebra $X(gl_n)$ on the vector space

$$\text{Hom}_{f_m}(V', V \otimes G(\mathbb{C}^m \otimes \mathbb{C}^n)).$$

(0.10)

The group $G_n$ also acts on this vector space, via its natural action on $\mathbb{C}^n$.

When $g_n$ is an orthogonal Lie algebra, the space (0.10) is irreducible under the joint action of $X(g_n)$ and $G_n$. When $g_n$ is symplectic, (0.10) is irreducible under the action of the $X(g_n)$ alone. Our Theorem 6.1 states that the action of $X(g_n)$ on (0.10) is essentially the same as the action obtained from the bimodule $F_m(V) = V \otimes G(\mathbb{C}^m \otimes \mathbb{C}^n)$ of $X(g_n)$ and $f_m$. More precisely, the action of $X(g_n)$ on the vector space (0.10) provided by [O2] can also be obtained from an action of $X(g_n)$ on the target $f_m$-module $V \otimes G(\mathbb{C}^m \otimes \mathbb{C}^n)$ in (0.10). The latter action is not exactly that on $F_m(V)$, but is defined by the composition

$$X(g_n) \to X(g_n) \xrightarrow{\beta_m} U(f_m) \otimes GD(\mathbb{C}^m \otimes \mathbb{C}^n)$$

where the first map is the automorphism (1.17) with $f(u)$ given by (6.6). The second map is the defining homomorphism of the $X(g_n)$-module $F_m(V)$. This third property of $F_m$ was the origin of our definition of this functor. Thus we have two different descriptions of the same action of $X(g_n)$ on (0.10). Another two, still different descriptions of the same action of $X(g_n)$ on the vector space (0.10) were provided in [M] and [N] respectively.

The functor $F_m$ here is an “antisymmetric” version of a functor introduced in [KN3]. The exterior algebra $\Lambda(\mathbb{C}^m \otimes \mathbb{C}^n)$ here replaces the symmetric algebra $S(\mathbb{C}^m \otimes \mathbb{C}^n)$ in [KN3]. Analogues of the three fundamental properties of $F_m$ were also given in [KN3].

1. Twisted Yangians

Let $G_n$ be one of the complex Lie groups $O_n$ and $Sp_n$. We regard $G_n$ as the subgroup of the general linear Lie group $GL_n$, preserving a non-degenerate bilinear form $\langle , \rangle$ on the vector space $\mathbb{C}^n$. This form is symmetric in the case $G_n = O_n$, and alternating in the case $G_n = Sp_n$. In the latter case $n$ has to be even. We always assume that the integer $n$ is positive. Throughout this article, we will use the following convention. Whenever the double sign $\pm$ or $\mp$ appears, the upper sign corresponds to the case $G_n = O_n$ while the lower sign corresponds to the case $G_n = Sp_n$.
Let \( i \) be any of the indices \( 1, \ldots, n \). If \( i \) is even, put \( \tilde{i} = i - 1 \). If \( i \) is odd and \( i < n \), put \( \tilde{i} = i + 1 \). Finally, if \( i = n \) and \( n \) is odd, put \( \tilde{i} = i \). Let \( e_1, \ldots, e_n \) be the vectors of the standard basis in \( \mathbb{C}^n \). Choose the bilinear form on \( \mathbb{C}^n \) so that for any two basis vectors \( e_i \) and \( e_j \) we have \( \langle e_i, e_j \rangle = \theta_i \delta_{ij} \) where \( \theta_i = 1 \) or \( \theta_i = (-1)^{i-1} \) in the case of the symmetric or alternating form.

Let \( E_{ij} \in \text{End}(\mathbb{C}^n) \) be the standard matrix units. We will also regard these matrix units as basis elements of the general linear Lie algebra \( \mathfrak{gl}_n \). Let \( \mathfrak{g}_n \) be the Lie algebra of the group \( G_n \), so that \( \mathfrak{g}_n = \mathfrak{so}_n \) or \( \mathfrak{g}_n = \mathfrak{sp}_n \) in the case of the symmetric or alternating form on \( \mathbb{C}^n \). The Lie subalgebra \( \mathfrak{g}_n \subset \mathfrak{gl}_n \) is spanned by the elements \( E_{ij} - \theta_i \theta_j E_{ji} \).

Take the Yangian \( Y(\mathfrak{gl}_n) \) of the Lie algebra \( \mathfrak{gl}_n \). The unital associative algebra \( Y(\mathfrak{gl}_n) \) over \( \mathbb{C} \) has a family of generators \( T_{ij}^{(1)}, T_{ij}^{(2)}, \ldots \) where \( i, j = 1, \ldots, n \). Defining relations for these generators can be written using the series

\[
T_{ij}(u) = \delta_{ij} + T_{ij}^{(1)} u^{-1} + T_{ij}^{(2)} u^{-2} + \ldots
\]

where \( u \) is a formal parameter. Let \( v \) be another formal parameter. Then the defining relations in the associative algebra \( Y(\mathfrak{gl}_n) \) can be written as

\[
(u - v) [T_{ij}(u), T_{kl}(v)] = T_{kj}(u) T_{il}(v) - T_{kj}(v) T_{il}(u).
\]

(1.1)

The algebra \( Y(\mathfrak{gl}_n) \) is commutative if \( n = 1 \). By (1.1), for any \( z \in \mathbb{C} \) the assignments

\[
\tau_z : T_{ij}(u) \mapsto T_{ij}(u - z)
\]

(1.2)

define an automorphism \( \tau_z \) of the algebra \( Y(\mathfrak{gl}_n) \). Here each of the formal power series \( T_{ij}(u - z) \) in \( (u - z)^{-1} \) should be re-expanded in \( u^{-1} \), and every assignment (1.2) is a correspondence between the respective coefficients of series in \( u^{-1} \). Relations (1.1) also show that for any formal power series \( g(u) \) in \( u^{-1} \) with coefficients from \( \mathbb{C} \) and leading term 1, the assignments

\[
T_{ij}(u) \mapsto g(u) T_{ij}(u)
\]

(1.3)

define an automorphism of the algebra \( Y(\mathfrak{gl}_n) \). Using (1.1), one can directly verify that the assignments

\[
T_{ij}(u) \mapsto \delta_{ij} + E_{ij} u^{-1}
\]

(1.4)

define a homomorphism of unital associative algebras \( Y(\mathfrak{gl}_n) \rightarrow U(\mathfrak{gl}_n) \).

There is an embedding \( U(\mathfrak{gl}_n) \rightarrow Y(\mathfrak{gl}_n) \), defined by mapping \( E_{ij} \mapsto T_{ij}^{(1)} \). So \( Y(\mathfrak{gl}_n) \) contains the universal enveloping algebra \( U(\mathfrak{gl}_n) \) as a subalgebra. The homomorphism (1.4) is identical on the subalgebra \( U(\mathfrak{gl}_n) \subset Y(\mathfrak{gl}_n) \).

Let \( T(u) \) be the \( n \times n \) matrix whose \( i, j \) entry is the series \( T_{ij}(u) \). The relations (1.1) can be rewritten by using the Yang \( R \)-matrix. This is the \( n^2 \times n^2 \) matrix

\[
R(u) = u - \sum_{i,j=1}^{n} E_{ij} \otimes E_{ji}
\]

(1.5)

where the tensor factors \( E_{ij} \) and \( E_{ji} \) are regarded as \( n \times n \) matrices. Note that

\[
R(u) R(-u) = 1 - u^2.
\]

(1.6)
Take \( n^2 \times n^2 \) matrices whose entries are series with coefficients from \( Y(\mathfrak{gl}_n) \),

\[
T_1(u) = T(u) \otimes 1 \quad \text{and} \quad T_2(v) = 1 \otimes T(v).
\]

The collection of relations (1.1) for all possible indices \( i, j, k, l \) can be written as

\[
R(u - v) T_1(u) T_2(v) = T_2(v) T_1(u) R(u - v).
\] (1.7)

Using this form of the defining relations together with (1.6), one shows that

\[
T(u) \mapsto T(-u)^{-1}
\] (1.8)

defines an involutive automorphism of the algebra \( Y(\mathfrak{gl}_n) \). Here each entry of the inverse matrix \( T(-u)^{-1} \) is a formal power series in \( u^{-1} \) with coefficients from the algebra \( Y(\mathfrak{gl}_n) \), and the assignment (1.8) is as a correspondence between the respective matrix entries.

The Yangian \( Y(\mathfrak{gl}_n) \) is a Hopf algebra over the field \( \mathbb{C} \). The comultiplication \( \Delta : Y(\mathfrak{gl}_n) \to Y(\mathfrak{gl}_n) \otimes Y(\mathfrak{gl}_n) \) is defined by the assignment

\[
\Delta : T_{ij}(u) \mapsto \sum_{k=1}^{n} T_{ik}(u) \otimes T_{kj}(u).
\] (1.9)

When taking tensor products of \( Y(\mathfrak{gl}_n) \)-modules, we use the comultiplication (1.9). The counit homomorphism \( Y(\mathfrak{gl}_n) \to \mathbb{C} \) is defined by the assignment \( T_{ij}(u) \mapsto \delta_{ij} \). The antipodal map \( Y(\mathfrak{gl}_n) \to Y(\mathfrak{gl}_n) \) is defined by the assignment \( T(u) \mapsto T(u)^{-1} \). This map is an anti-automorphism of the associative algebra \( Y(\mathfrak{gl}_n) \). For further details on the Hopf algebra structure on \( Y(\mathfrak{gl}_n) \) see [MNO, Chapter 1].

Let \( T'(u) \) be the transpose to the matrix \( T(u) \) relative to the form \( \langle , \rangle \) on \( \mathbb{C}^n \). The \( i, j \) entry of the matrix \( T'(u) \) is \( \theta_i \theta_j T_{ji}(u) \). Define the \( n^2 \times n^2 \) matrices

\[
T_1'(u) = T'(u) \otimes 1 \quad \text{and} \quad T_2'(v) = 1 \otimes T'(v).
\]

Note that the Yang \( R \)-matrix (1.5) is invariant under applying the transposition relative to \( \langle , \rangle \) to both tensor factors. Hence the relation (1.7) implies that

\[
R(u - v) T_1'(u) T_2'(v) R(u - v) = R(u - v) T_2'(v) T_1'(u),
\]

\[
R(u - v) T_1'(-u) T_2'(-v) = T_2'(-v) T_1'(-u) R(u - v).
\] (1.10)

To obtain the latter relation, we used (1.6). By comparing (1.7) and (1.10), an involutive automorphism of the algebra \( Y(\mathfrak{gl}_n) \) can be defined by the assignment

\[
T(u) \mapsto T'(-u).
\] (1.11)

This assignments is understood as a correspondence between respective matrix entries.

Now take the product \( T'(-u) T(u) \). The \( i, j \) entry of this matrix is the series

\[
\sum_{k=1}^{n} \theta_i \theta_k T_{ki}(-u) T_{kj}(u).
\] (1.12)
The twisted Yangian corresponding to the form $\langle \ , \rangle$ is the subalgebra of $Y(\mathfrak{gl}_n)$ generated by coefficients of all series (1.12). We denote this subalgebra by $Y(\mathfrak{gl}_n)$.

To give defining relations for these generators of $Y(\mathfrak{gl}_n)$, let us introduce the extended twisted Yangian $X(\mathfrak{g}_n)$. The unital associative algebra $X(\mathfrak{g}_n)$ has a family of generators $S_{ij}^{(1)}, S_{ij}^{(2)}, \ldots$ where $i, j = 1, \ldots, n$. Put

$$S_{ij}(u) = \delta_{ij} + S_{ij}^{(1)} u^{-1} + S_{ij}^{(2)} u^{-2} + \ldots$$

and let $S(u)$ be the $n \times n$ matrix whose $i, j$ entry is the series $S_{ij}(u)$. Also introduce the $n^2 \times n^2$ matrix

$$R'(u) = u - \sum_{i,j=1}^{n} \theta_i \theta_j E_{ij} \otimes E_{\bar{i}\bar{j}}$$

(1.13)

which is obtained from the Yang $R$-matrix (1.5) by applying to any of the two tensor factors the transposition relative to the form $\langle \ , \rangle$ on $\mathbb{C}^n$. Note the relation

$$R'(u) R'(n-u) = u(n-u).$$

(1.14)

Take $n^2 \times n^2$ matrices whose entries are series with coefficients from the algebra $X(\mathfrak{g}_n)$,

$$S_1(u) = S(u) \otimes 1 \quad \text{and} \quad S_2(v) = 1 \otimes S(v).$$

Defining relations in the algebra $X(\mathfrak{g}_n)$ can then be written as a single matrix relation

$$R(u-v) S_1(u) R'(-u-v) S_2(v) = S_2(v) R'(-u-v) S_1(u) R(u-v).$$

(1.15)

It is equivalent to the collection of relations

$$(u^2 - v^2) [S_{ij}(u), S_{kl}(v)] = (u + v)(S_{kj}(u) S_{il}(v) - S_{kj}(v) S_{il}(u))$$

$$\mp (u - v)(\theta_k \theta_j S_{i\bar{k}}(u) S_{\bar{j}l}(v) - \theta_i \theta_l S_{k\bar{i}}(v) S_{\bar{j}l}(u))$$

$$\pm \theta_i \theta_j (S_{k\bar{i}}(u) S_{\bar{j}l}(v) - S_{k\bar{i}}(v) S_{\bar{j}l}(u)).$$

(1.16)

Similarly to (1.3), this collection of relations shows that for any formal power series $f(u)$ in $u^{-1}$ with the coefficients from $\mathbb{C}$ and leading term 1, the assignments

$$S_{ij}(u) \mapsto f(u) S_{ij}(u)$$

(1.17)

define an automorphism of the algebra $X(\mathfrak{g}_n)$. See [KN3, Section 1] for the proof of

**Proposition 1.1.** One can define a homomorphism $X(\mathfrak{g}_n) \rightarrow Y(\mathfrak{g}_n)$ by assigning

$$S(u) \mapsto T'(-u) T(u).$$

(1.18)

By definition, the homomorphism (1.18) is surjective. Further, the algebra $X(\mathfrak{g}_n)$ has a distinguished family of central elements. Indeed, by dividing each side of the equality (1.15) by $S_2(v)$ on the left and right and then setting $v = -u$, we get

$$R'(0) S_1(u) R(2u) S_2(-u)^{-1} = S_2(-u)^{-1} R(2u) S_1(u) R'(0).$$
The rank of the matrix $R'(0)$ equals 1. So the last displayed equality implies existence of a formal power series $O(u)$ in $u^{-1}$ with the coefficients in $X(\mathfrak{g}_n)$ and leading term 1, such that

$$R'(0)S_1(u)R(2u)S_2(-u)^{-1} = (2u \mp 1)O(u)R'(0). \quad (1.19)$$

By [MNO, Theorem 6.3] all coefficients of the series $O(u)$ belong to the centre of $X(\mathfrak{g}_n)$.

Let us write $O(u) = 1 + O^{(1)}u^{-1} + O^{(2)}u^{-2} + \ldots$.

By [MNO, Theorem 6.4] the kernel of the homomorphism (1.18) coincides with the (two-sided) ideal generated by the central elements $O^{(1)}, O^{(2)}, \ldots$ defined as coefficients of the series $O(u)$. Using (1.6), one derives from (1.19) the relation $O(u)O(-u) = 1$.

Thus the twisted Yangian $Y(\mathfrak{g}_n)$ can be defined as the associative algebra with the generators $S^{(1)}_{ij}, S^{(2)}_{ij}, \ldots$ which satisfy the relation $O(u) = 1$ and the reflection equation (1.15). For more details on the definition of the algebra $Y(\mathfrak{g}_n)$ see [MNO, Chapter 3].

In the present article we need the algebra $X(\mathfrak{g}_n)$ which is determined by (1.15) alone, because this algebra admits an analogue of the automorphism (1.8) of the Yangian $Y(\mathfrak{g}_n)$. Indeed, using (1.15) together with the relations (1.6) and (1.14), one shows that the assignment

$$\omega_n : S(u) \mapsto S(-u - n/2)^{-1} \quad (1.20)$$

defines an involutive automorphism $\omega_n$ of $X(\mathfrak{g}_n)$. However, $\omega_n$ does not determine an automorphism of the algebra $Y(\mathfrak{g}_n)$, because the map $\omega_n$ does not preserve the ideal of $X(\mathfrak{g}_n)$ generated by the elements $O^{(1)}, O^{(2)}, \ldots$; see [MNO, Section 6.6]. Note that by multiplying (1.19) on the right by $S_2(-u)$, the relation $O(u) = 1$ can be rewritten as

$$S'(u) = S(-u) \pm \frac{S(u) - S(-u)}{2u} \quad (1.21)$$

where $S'(u)$ is the transpose to the matrix $S(u)$ relative to the form $\langle , \rangle$ on $\mathbb{C}^n$.

The definition (1.19) of the series $O(u)$ implies that the assignment (1.17) determines an automorphism of the quotient algebra $Y(\mathfrak{g}_n)$ of $X(\mathfrak{g}_n)$, if and only if $f(u) = f(-u)$. If $z \neq 0$, the automorphism $\tau_z$ of $Y(\mathfrak{g}_n)$ does not preserve the subalgebra $Y(\mathfrak{g}_n) \subset Y(\mathfrak{gl}_n)$. There is no analogue of the automorphism $\tau_z$ for the algebra $X(\mathfrak{g}_n)$.

However, there is an analogue of the homomorphism $Y(\mathfrak{gl}_n) \rightarrow U(\mathfrak{gl}_n)$ defined by (1.4). Namely, one can define a homomorphism $\pi_n : X(\mathfrak{g}_n) \rightarrow U(\mathfrak{g}_n)$ by the assignments

$$\pi_n : S_{ij}(u) \mapsto \delta_{ij} + \frac{E_{ij} - \theta_i \theta_j E_{ji}}{u \pm \frac{1}{2}} \quad (1.22)$$

This can be proved by using the defining relations (1.16), see [MNO, Proposition 3.11]. Furthermore, the central elements $O^{(1)}, O^{(2)}, \ldots$ of $X(\mathfrak{g}_n)$ belong to the kernel of $\pi_n$. Thus $\pi_n$ factors through the homomorphism $X(\mathfrak{g}_n) \rightarrow Y(\mathfrak{g}_n)$ defined by (1.18).

Further, there is an embedding $U(\mathfrak{g}_n) \rightarrow Y(\mathfrak{g}_n)$ defined by mapping each element $E_{ij} - \theta_i \theta_j E_{ji} \in \mathfrak{g}_n$ to the coefficient at $u^{-1}$ of the series (1.12). Hence $Y(\mathfrak{g}_n)$ contains the universal enveloping algebra $U(\mathfrak{g}_n)$ as a subalgebra. The homomorphism $Y(\mathfrak{g}_n) \rightarrow U(\mathfrak{g}_n)$ corresponding to $\pi_n$ is evidently identical on the subalgebra $U(\mathfrak{g}_n) \subset Y(\mathfrak{g}_n)$.

For any positive integer $l$, consider the vector space $\mathbb{C}^l$ and the corresponding Lie algebra $\mathfrak{gl}_l$. Let $E_{ab} \in \text{End} (\mathbb{C}^l)$ with $a, b = 1, \ldots, l$ be the standard matrix units. When
regarding these matrix units as generators of the universal enveloping algebra $U(\mathfrak{gl}_n)$, introduce the $l \times l$ matrix $E$ whose $a,b$ entry is the generator $E_{ab}$. Denote by $E'$ the $l \times l$ matrix whose $a,b$ entry is the generator $E_{ba}$. Then consider the matrix inverse $(u - E')^{-1}$. The $a,b$ entry $(u - E')^{-1}_{ab}$ of the inverse matrix is a formal power series in $u^{-1}$ with the leading term $\delta_{ab} u^{-1}$ and the coefficients from the algebra $U(\mathfrak{gl}_l)$.

Take the tensor product of the vector spaces $\mathbb{C}^l \otimes \mathbb{C}^n$. Let $x_{ai}$ with $a = 1, \ldots, l$ and $i = 1, \ldots, n$ be the standard coordinate functions on $\mathbb{C}^l \otimes \mathbb{C}^n$. Consider the Grassmann algebra $G(\mathbb{C}^l \otimes \mathbb{C}^n)$. It is generated by the elements $x_{ai}$ subject to the anticommutation relations $x_{ai} x_{bj} = -x_{bj} x_{ai}$ for all indices $a,b = 1, \ldots, l$ and $i,j = 1, \ldots, n$. We will denote the operator of the left multiplication by $x_{ai}$ on $G(\mathbb{C}^l \otimes \mathbb{C}^n)$ by the same symbol. Let $\partial_{ai}$ be the operator of left derivation on $G(\mathbb{C}^l \otimes \mathbb{C}^n)$ corresponding to the variable $x_{ai}$, it is also called the inner multiplication in $G(\mathbb{C}^l \otimes \mathbb{C}^n)$ corresponding to $x_{ai}$.

The ring of $\mathbb{C}$-endomorphisms of $G(\mathbb{C}^l \otimes \mathbb{C}^n)$ is generated by all operators $x_{ai}$ and $\partial_{ai}$, see for instance [H, Appendix 2.3]. This ring will be denoted by $\mathcal{GD}(\mathbb{C}^l \otimes \mathbb{C}^n)$. In this ring, we have

$$x_{ai} \partial_{bj} + \partial_{bj} x_{ai} = \delta_{ab} \delta_{ij}.$$  

Hence the ring $\mathcal{GD}(\mathbb{C}^l \otimes \mathbb{C}^n)$ is isomorphic to the Clifford algebra corresponding to the direct sum of the vector space $\mathbb{C}^l \otimes \mathbb{C}^n$ with its dual.

The Lie algebra $\mathfrak{gl}_l$ acts on the vector space $G(\mathbb{C}^l \otimes \mathbb{C}^n)$ so that the generator $E_{ab}$ acts as the operator

$$\sum_{k=1}^{n} x_{ak} \partial_{bk}.$$  

Denote by $A_l$ the tensor product of associative algebras $U(\mathfrak{gl}_l) \otimes \mathcal{GD}(\mathbb{C}^l \otimes \mathbb{C}^n)$. We have an embedding $U(\mathfrak{gl}_l) \rightarrow A_l$ defined for $a,b = 1, \ldots, l$ by the mappings

$$E_{ab} \mapsto E_{ab} \otimes 1 + \sum_{k=1}^{n} 1 \otimes x_{ak} \partial_{bk}.$$  

The following proposition was proved in [KN2, Section 1], see also [A, Section 3].

**Proposition 1.2.** (i) One can define a homomorphism $\alpha_l : Y(\mathfrak{gl}_n) \rightarrow A_l$ by mapping

$$\alpha_l : T_{ij}(u) \mapsto \delta_{ij} + \sum_{a,b=1}^{l} (u - E')^{-1}_{ab} \otimes x_{ai} \partial_{bj}.$$  

(ii) The image of $Y(\mathfrak{gl}_n)$ in $A_l$ relative to this homomorphism commutes with the image of $U(\mathfrak{gl}_l)$ in $A_l$ relative to the embedding (1.25).

Note that

$$\alpha_1 : T_{ij}^{(1)} \mapsto \sum_{c=1}^{l} 1 \otimes x_{ci} \partial_{cj}.$$  

Hence the restriction of the homomorphism $\alpha_l$ to the subalgebra $U(\mathfrak{gl}_n) \subset Y(\mathfrak{gl}_n)$ corresponds to the natural action of the Lie algebra $\mathfrak{gl}_n$ on $G(\mathbb{C}^l \otimes \mathbb{C}^n)$.

Denote by $Z(u)$ the trace of the inverse matrix $(u + E)^{-1}$, so that
Then $Z(u)$ is a formal power series in $u^{-1}$ with the coefficients from the algebra $U(\mathfrak{gl}_l)$. It is well known that these coefficients actually belong to the centre $Z(\mathfrak{gl}_l)$ of $U(\mathfrak{gl}_l)$. Note that the leading term of this series is $lu^{-1}$.

Let us choose the Borel subalgebra $b$ of the Lie algebra $\mathfrak{gl}_l$ spanned by the elements $E_{ab}$ where $a \leq b$. Let $t \subset b$ be the Cartan subalgebra of $\mathfrak{gl}_l$ with the basis $(E_{11}, \ldots, E_{ll})$. Consider the corresponding Harish-Chandra homomorphism $\varphi_l : U(\mathfrak{gl}_l)^l \rightarrow U(t)$. By definition, for any $t$-invariant element $X \in U(\mathfrak{gl}_l)$ the difference $X - \varphi_l(X)$ belongs to the left ideal of $U(\mathfrak{gl}_l)$ generated by the elements $E_{ab}$ where $a < b$. Restriction of the homomorphism $\varphi_l$ to $Z(\mathfrak{gl}_l) \subset U(\mathfrak{gl}_l)^l$ is injective. It is well known that

$$1 + \varphi_l(Z(u)) = \prod_{a=1}^{l} \left(1 + \frac{1}{u + l - a + E_{aa}}\right),$$

(1.28)

see for instance [PP, Theorem 3]. For the proof of the next lemma see [KN3, Section 1] where the parameter $u$ should be now replaced by $-u$.

**Lemma 1.3.** For any indices $a, d = 1, \ldots, l$ we have the equality

$$(u + E)^{-1}_{aa} = (1 + Z(u))(u + l + E')^{-1}_{ad}.$$

Now let $U$ be a module of the Lie algebra $\mathfrak{gl}_l$. Using the homomorphism (1.26) we can turn the tensor product of $\mathfrak{gl}_l$-modules $U \otimes \mathcal{G}(C^l \otimes C^n)$ to a bimodule over $\mathfrak{gl}_l$ and $Y(\mathfrak{gl}_n)$. This bimodule is denoted by $\mathcal{E}_l(U)$. More generally, for $z \in C$ denote by $\mathcal{E}_l^z(U)$ the $Y(\mathfrak{gl}_n)$-module obtained from $\mathcal{E}_l(U)$ via pull-back through the automorphism $\tau_z$ of $Y(\mathfrak{gl}_n)$, see (1.2). It is determined by the homomorphism $Y(\mathfrak{gl}_n) \rightarrow A_l$ such that

$$T_{ij}(u) \mapsto \delta_{ij} + \sum_{a,b=1}^{l} (u + z - E')^{-1}_{ab} \otimes x_{ai} \partial_{bj}$$

for any $i, j = 1, \ldots, n$. As a $\mathfrak{gl}_l$-module $\mathcal{E}_l^z(U)$ coincides with $\mathcal{E}_l(U)$ by definition. In the next section we will introduce analogues of the homomorphism (1.25) and of the correspondence $U \mapsto \mathcal{E}_l(U)$ for the twisted Yangian $Y(\mathfrak{g}_n)$ instead of $Y(\mathfrak{gl}_n)$.

### 2. Howe duality

We will work with one of the pairs ($\mathfrak{so}_{2m}, O_n$) and ($\mathfrak{sp}_{2m}, Sp_n$). The second member of the pair will be the Lie group $G_n$. The first member will be the Lie algebra $\mathfrak{f}_m$ defined below. These pairs appear in the context of the skew Howe duality, see [H, Section 4.3].

Take the even-dimensional vector space $C^{2m}$. Equip $C^{2m}$ with a non-degenerate bilinear form, symmetric in the case $G_n = O_n$ and alternating in the case $G_n = Sp_n$. Let $\mathfrak{f}_m$ be the subalgebra of the general Lie algebra $\mathfrak{gl}_{2m}$ preserving our bilinear form on $C^{2m}$. We have $\mathfrak{f}_m = \mathfrak{so}_{2m}$ or $\mathfrak{f}_m = \mathfrak{sp}_{2m}$ respectively in the case of a symmetric or an alternating form on $C^{2m}$.
Let us label the standard basis vectors of $\mathbb{C}^{2m}$ by the numbers $-m, \ldots, -1, 1, \ldots, m$. Let $E_{ab} \in \text{End}(\mathbb{C}^{2m})$ be the standard matrix units, where the indices $a, b$ run through these numbers. We will also regard these matrix units as basis elements of $\mathfrak{gl}_{2m}$. Put

$$\varepsilon_{ab} = 1 \quad \text{or} \quad \varepsilon_{ab} = \text{sign } a \cdot \text{sign } b$$

respectively in the case of a symmetric or an alternating form on $\mathbb{C}^{2m}$. Then choose the form on $\mathbb{C}^{2m}$ so that the Lie subalgebra $\mathfrak{f}_m \subset \mathfrak{gl}_{2m}$ is spanned by the elements

$$F_{ab} = E_{ab} - \varepsilon_{ab} E_{-b,-a}.$$  \hspace{1cm} (2.2)

In the universal enveloping algebra $U(\mathfrak{f}_m)$ we have the commutation relations

$$[F_{ab}, F_{cd}] = \delta_{cb} F_{ad} - \delta_{ad} F_{cb} - \varepsilon_{ab} \delta_{c,-a} F_{-b,d} + \varepsilon_{ab} \delta_{-b,d} F_{c,-a}.$$  \hspace{1cm} (2.3)

Let $F$ be the $2m \times 2m$ matrix whose $a, b$ entry is the element $F_{ab}$. Denote by $F(u)$ the inverse to the matrix $u + F$. Let $F_{ab}(u)$ be the $a, b$ entry of the inverse matrix. Any of these entries may be regarded as a formal power series in $u^{-1}$ with the coefficients from the algebra $U(\mathfrak{f}_m)$. Then

$$F_{ab}(u) = \delta_{ab} u^{-1} + \sum_{s=0}^{\infty} \sum_{|c_1|, \ldots, |c_s|=1} (-1)^{s+1} F_{ac_1} F_{c_1 c_2} \cdots F_{c_{s-1} c_s} F_{c_s b} u^{-s-2}.$$  \hspace{1cm} (2.4)

When $s = 0$, the sum over $c_1, \ldots, c_s$ in (2.4) is understood as $-F_{ab} u^{-2}$. Let us denote by $W(u)$ the trace of the matrix $F(u)$, that is

$$W(u) = \sum_{|c|=1} F_{cc} (u).$$  \hspace{1cm} (2.5)

The coefficients of the series $W(u)$ belong to the centre $Z(\mathfrak{f}_m)$ of the algebra $U(\mathfrak{f}_m)$.

In what follows, the upper signs in $\pm$ and $\mp$ correspond to the case of a symmetric form on $\mathbb{C}^{2m}$ while the lower signs correspond to the case of an alternating form on $\mathbb{C}^{2m}$. In these cases we also have respectively a symmetric or alternating form on $\mathbb{C}^n$. Thus the choice of signs in $\pm$ and $\mp$ here agrees with our general convention on double signs. Let $F'(u)$ be the transpose to the matrix $F(u)$ relative to our bilinear form on $\mathbb{C}^{2m}$ so that the $a, b$ entry $F_{ab}'(u)$ of the matrix $F'(u)$ equals $\varepsilon_{ab} F_{-b,-a}(u)$. For the proof of next proposition see [KN3, Section 2] where $u$ should be now replaced by $-u$.

**Proposition 2.1.** We have the equality of $2m \times 2m$ matrices

$$-F'(u) = (W(u) \mp \frac{1}{2u + 2m \mp 1} + 1) F(-u - 2m \pm 1) \mp \frac{F(u)}{2u + 2m \mp 1}.$$  \hspace{1cm} (2.6)

**Corollary 2.2.** We have the equality

$$(W(u) \mp \frac{1}{2u + 2m \mp 1} + 1) (W(-u - 2m \pm 1) \pm \frac{1}{2u + 2m \mp 1} + 1)$$

$$= 1 - \frac{1}{(2u + 2m \mp 1)^2}. $$
On the space $\mathbb{C}^m \otimes \mathbb{C}^n$, we have the coordinate functions $x_{ai}$ where $a = 1, \ldots, m$ and $i = 1, \ldots, n$. Consider the Grassmann algebra $\mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n)$ corresponding to this vector space. We will denote the operator of the left multiplication by $x_{ai}$ on $\mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n)$ by the same symbol. Let $\partial_{ai}$ be the left derivation on $\mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n)$ relative to $x_{ai}$. There is an action of $f_m$ on $\mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n)$, commuting with the natural action of the group $G_n$. The corresponding homomorphism $\zeta_n : U(f_m) \to \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n)$ is defined by the following mappings for $a, b = 1, \ldots, m$:

$$\zeta_n : F_{ab} \mapsto -\delta_{ab} n/2 + \sum_{k=1}^n x_{ak} \partial_{bk},$$

$$F_{a,-b} \mapsto \sum_{k=1}^n \theta_k x_{a_k} x_{b_k}, \quad F_{-a,b} \mapsto \sum_{k=1}^n \theta_k \partial_{a_k} \partial_{b_k}. \quad (2.6)$$

The homomorphism property here can be verified by using the relations (2.3). Moreover, the image of the homomorphism $\zeta_n$ coincides with the subring of all $G_n$-invariants in $\mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n)$; see [H, Subsections 3.8.7 and 4.3.3]. Let $B_m$ be the tensor product of associative algebras $U(f_m) \otimes \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n)$. Take the embedding $U(f_m) \to B_m$ defined by mapping

$$X \mapsto X \otimes 1 + 1 \otimes \zeta_n(X) \quad \text{for each} \quad X \in f_m. \quad (2.7)$$

**Proposition 2.3.** (i) One can define a homomorphism $\beta_m : X(g_n) \to B_m$ so that the series $S_{ij}(u)$ is mapped to the series with coefficients in the algebra $B_m$:

$$\delta_{ij} + \sum_{a,b=1}^m (F_{-a,-b}(u + \frac{1}{2} - m) \otimes x_{ai} \partial_{bj} + F_{-a,b}(u + \frac{1}{2} - m) \otimes \theta_j x_{ai} x_{bj}$$

$$+ F_{a,-b}(u + \frac{1}{2} - m) \otimes \theta_i \partial_{ai} \partial_{bj} + F_{ab}(u + \frac{1}{2} - m) \otimes \theta_i \theta_j \partial_{ai} x_{bj}). \quad (2.8)$$

(ii) The image of $X(g_n)$ in $B_m$ relative to this homomorphism commutes with the image of $U(f_m)$ in $B_m$ relative to the embedding (2.7).

Proposition 2.3 can be proved by direct calculation using the defining relations (1.16). That calculation is omitted here. In Section 6 we will give a more conceptual proof of the proposition. Now let the indices $c$ and $d$ run through the sequence $-m, \ldots, -1, 1, \ldots, m$. For $c < 0$ put $p_{ci} = x_{-c,i}$ and $q_{ci} = \partial_{-c,i}$. For $c > 0$ put $p_{ci} = \theta_i \partial_{ci}$ and $q_{ci} = \theta_i x_{ci}$. Then our definition of the homomorphism $\beta_m$ can be written as

$$\beta_m : S_{ij}(u) \mapsto \delta_{ij} + \sum_{|c|,|d|=1}^m F_{cd}(u + \frac{1}{2} - m) \otimes p_{ci} q_{dj}, \quad (2.9)$$

similarly to (1.26). Moreover, then by the definition (2.6)

$$\zeta_n : F_{cd} \mapsto -\delta_{cd} n/2 + \sum_{k=1}^n q_{ck} p_{dk}. \quad (2.10)$$
Using (2.5), let us define a formal power series \( \hat{W}(u) \) in \( u^{-1} \) with coefficients in the centre \( Z(f_m) \) of the algebra \( U(f_m) \) by the equation

\[
(1 \mp \frac{1}{2u}) \hat{W}(u) = W(u \pm \frac{1}{2} - m).
\]

By Corollary 2.2,

\[
(\hat{W}(u) + 1) (\hat{W}(u) - 1) = 1.
\]

Hence there is a formal power series \( \tilde{W}(u) \) in \( u^{-1} \) with coefficients in \( Z(f_m) \) and leading term 1, such that

\[
\tilde{W}(-u) \tilde{W}(u)^{-1} = 1 + \hat{W}(u). \tag{2.11}
\]

The series \( \tilde{W}(u) \) is not unique. But its coefficient at \( u^{-1} \) is always \(-m\), because the leading term of the series \( W(u) \) is \( 2mu^{-1} \). Let \( \tilde{\beta}_m \) be the homomorphism \( X(g_n) \to B_m \) defined by assigning to \( S_{ij}(u) \) the series (2.8) multiplied by \( \tilde{W}(u) \) \( \otimes \) \( 1 \in B_m[[u^{-1}]] \). \( \tag{2.12} \)

The homomorphism property of \( \tilde{\beta}_m \) follows from Part (i) of Proposition 2.3, see also the defining relations (1.16). Part (ii) implies that the image of \( \tilde{\beta}_m \) commutes with the image of \( U(f_m) \) in the algebra \( B_m \) relative to the embedding (2.7).

**Proposition 2.4.** The elements \( O^{(1)}, O^{(2)}, \ldots \) of \( X(g_n) \) belong to the kernel of \( \tilde{\beta}_m \).

**Proof.** Let us denote by \( \tilde{S}_{ij}(u) \) the product of the series (2.8) and (2.12). Using the equivalent presentation (1.21) of the relation \( O(u) = 1 \), we have to prove the equality

\[
\theta_i \theta_j \tilde{S}_{ji}(u) = \tilde{S}_{ij}(-u) \pm \frac{\tilde{S}_{ij}(u) - \tilde{S}_{ij}(-u)}{2u} \tag{2.13}
\]

for any \( i, j = 1, \ldots, n \). By the definition of the series \( \tilde{W}(u) \), we have the relation

\[
\tilde{W}(u) (1 + W(u \pm \frac{1}{2} - m)) = \tilde{W}(-u) \pm \frac{\tilde{W}(u) - \tilde{W}(-u)}{2u}. \tag{2.14}
\]

Further, let us introduce the \( 2m \times 2m \) matrix

\[
\tilde{F}(u) = \tilde{W}(u) F(u \pm \frac{1}{2} - m) \tag{2.15}
\]

and its transpose \( \tilde{F}'(u) \) relative to our bilinear form on \( \mathbb{C}^{2m} \). By Proposition 2.1,

\[
\tilde{F}'(u) = -\tilde{F}(-u) \mp \frac{\tilde{F}(u) - \tilde{F}(-u)}{2u}. \tag{2.16}
\]

By changing the indices \( i, j \) in (2.8) respectively to \( j, i \) and multiplying the resulting series by \( \theta_i \theta_j \) we get

\[
\delta_{ij} + \sum_{a,b=1}^{m} (F_{-a,-b}(u \pm \frac{1}{2} - m) \otimes \theta_i \theta_j x_{aj} \partial_{bi} \pm F_{-a,b}(u \pm \frac{1}{2} - m) \otimes \theta_j x_{aj} x_{bi}
\]
\[ \pm F_{a,-b}(u \pm \frac{1}{2} - m) \otimes \theta_i \partial_{ai} \partial_{b} + F_{ab}(u \pm \frac{1}{2} - m) \otimes \partial_{aj} x_{bi} \]

\[ = (1 + W(u \pm \frac{1}{2} + m)) \otimes \delta_{ij} + \]

\[ \sum_{a,b=1}^{m} (F_{b,-a}(u \pm \frac{1}{2} - m) \otimes \theta_i \theta_j \partial_{ai} x_{bj} \mp F_{-b,a}(u \pm \frac{1}{2} - m) \otimes \theta_j x_{ai} x_{b}j) \]

\[ \mp F_{b,-a}(u \pm \frac{1}{2} - m) \otimes \theta_i \partial_{ai} \partial_{bj} - F_{ba}(u \pm \frac{1}{2} - m) \otimes x_{ai} \partial_{bj} \]

\[ = (1 + W(u \pm \frac{1}{2} - m)) \otimes \delta_{ij} \]

\[ - \sum_{a,b=1}^{m} (F'_{ab}(u \pm \frac{1}{2} - m) \otimes \theta_i \theta_j \partial_{ai} x_{bj} + F'_{-a,b}(u \pm \frac{1}{2} - m) \otimes \theta_j x_{ai} x_{b}j + F'_{a,-b}(u \pm \frac{1}{2} - m) \otimes x_{ai} \partial_{bj}) \]

Multiplying the expression in the last three lines by \( \tilde{W}(u) \otimes 1 \) and using the definition (2.15), we get

\[ \tilde{W}(u) (1 + W(u \pm \frac{1}{2} - m)) \otimes \delta_{ij} \]

\[ - \sum_{a,b=1}^{m} (\tilde{F}'_{ab}(u) \otimes \theta_i \theta_j \partial_{ai} x_{bj} + \tilde{F}'_{-a,b}(u) \otimes \theta_j x_{ai} x_{b}j + \tilde{F}'_{a,-b}(u) \otimes x_{ai} \partial_{bj}) \]

The required equality (2.13) now follows from (2.14) and (2.16).

So the homomorphism \( \tilde{\beta}_m : X(\mathfrak{g}_n) \to B_m \) factors to a homomorphism \( Y(\mathfrak{g}_n) \to B_m \).

This is an analogue of the homomorphism (1.26) for the twisted Yangian \( Y(\mathfrak{g}_n) \) instead of \( Y(\mathfrak{g}t_n) \). Recall that

\[ \tilde{W}(u) = 1 - m u^{-1} + \ldots \]

so that

\[ \tilde{\beta}_m : S^{(1)}_{ij} \mapsto -m \delta_{ij} + \sum_{c=1}^{m} (1 \otimes x_{ci} \partial_{cj} + 1 \otimes \theta_i \theta_j \partial_{ci} x_{cj}) \]

\[ = \sum_{c=1}^{m} (1 \otimes x_{ci} \partial_{cj} - 1 \otimes \theta_i \theta_j x_{cj} \partial_{ci} x_{cj}) \]

Thus for any formal power series \( \tilde{W}(u) \) in \( u^{-1} \) which has its coefficients in \( \mathbb{Z}(\mathfrak{f}_m) \), has the leading term 1 and satisfies the equation (2.11), the restriction of the homomorphism \( Y(\mathfrak{g}_n) \to B_m \) to the subalgebra \( U(\mathfrak{g}_n) \subset Y(\mathfrak{g}_n) \) corresponds to the natural action of the Lie algebra \( \mathfrak{g}_n \) on the vector space \( \mathcal{G}(\mathbb{C}^{m} \otimes \mathbb{C}^{n}) \).

The series \( \tilde{W}(u) \) is not unique, and it will be more convenient for us to work with the homomorphism \( \beta_m : X(\mathfrak{g}_n) \to B_m \) defined in Proposition 2.3. Using this homomorphism and the action of the Lie algebra \( \mathfrak{f}_m \) on \( \mathcal{G}(\mathbb{C}^{m} \otimes \mathbb{C}^{n}) \) as defined by (2.6), for arbitrary
$f_m$-module $V$ we can turn the tensor product $V \otimes G(\mathbb{C}^m \otimes \mathbb{C}^n)$ to a bimodule over $f_m$ and $X(g_n)$. This bimodule will be denoted by $F_m(V)$.

Consider the triangular decomposition of the Lie algebra $f_m$,

$$f_m = n \oplus h \oplus n'$$

(2.17)

where $h$ is the Cartan subalgebra of $f_m$ with the basis $(F_{-m,-m}, \ldots, F_{-1,-1})$. Further, $n$ and $n'$ are the nilpotent subalgebras of $f_m$ spanned by elements $F_{ab}$ where $a > b$ and $a < b$ respectively; the indices $a, b$ here can be positive or negative. For each $f_m$-module $V$, we will denote by $V_n$ the vector space $V/n \cdot V$ of coinvariants of the action of the subalgebra $n \subset f_m$ on $V$. The Cartan subalgebra $h \subset f_m$ acts on the vector space $V_n$.

Now consider the bimodule $F_m(V)$. The action of $X(g_n)$ on this bimodule commutes with the action of the Lie algebra $f_m$, and hence with the action of the subalgebra $n \subset f_m$. Therefore the space $F_m(V)_n$ of coinvariants of the action of $n$ is a quotient of the $X(g_n)$-module $F_m(V)$. Thus we get a functor from the category of all $f_m$-modules to the category of bimodules over $h$ and $X(g_n)$,

$$V \mapsto F_m(V)_n = (V \otimes G(\mathbb{C}^m \otimes \mathbb{C}^n))/n.$$

(2.18)

The assignments $E_{ab} \mapsto F_{ab}$ for all $a, b = 1, \ldots, m$ define a Lie algebra embedding $gl_m \rightarrow f_m$; see relations (2.3). Using this embedding, consider the decomposition

$$f_m = r \oplus gl_m \oplus r'$$

(2.19)

where $r$ and $r'$ are the Abelian subalgebras of $f_m$ spanned respectively by the elements $F_{a,-b}$ and $F_{-a,b}$ for all $a, b = 1, \ldots, m$. For any $gl_m$-module $U$, let $V$ be the $f_m$-module parabolically induced from the $gl_m$-module $U$. To define $V$, one first extends the action of the Lie algebra $gl_m$ on $U$ to the maximal parabolic subalgebra $gl_m \oplus r' \subset f_m$, so that every element of the summand $r'$ acts on $U$ as zero. By definition, $V$ is the $f_m$-module induced from the $gl_m \oplus r'$-module $U$. Note that here we have a canonical embedding $U \rightarrow V$ of $gl_m \oplus r'$-modules; we will denote by $\pi$ the image of an element $u \in U$ under this embedding. The $f_m$-module $V$ determines the bimodule $F_m(V)$ over $f_m$ and $X(g_n)$. The space of $r$-coinvariants $F_m(V)_r$ is then a bimodule over $gl_m$ and $X(g_n)$.

On the other hand, for any $z \in \mathbb{C}$ consider the bimodule $E^{z}_{m}(U)$ over the Lie algebra $gl_m$ and over the Yangian $Y(gl_n)$. By restricting the module $E^{z}_{m}(U)$ from the algebra $Y(gl_n)$ to its subalgebra $Y(g_n)$ and then by using the homomorphism $X(g_n) \rightarrow Y(g_n)$ defined by (1.18), we can regard $E^{z}_{m}(U)$ as a module over the algebra $X(g_n)$ instead of $Y(gl_n)$. This module is determined by the homomorphism $X(g_n) \rightarrow A_m$ such that for any $i, j = 1, \ldots, n$ the series $S_{ij}(u)$ is mapped to

$$\sum_{k=1}^{n} \theta_i \theta_k \alpha_m(T_{k\bar{i}}(u-z)T_{kj}(u+z));$$

(2.20)

see (1.12) and (1.26). Let us now map $S_{ij}(u)$ to the series (2.20) multiplied by

$$(1 + Z(u-z-m)) \otimes 1 \in A_m[[u^{-1}]];$$

(2.21)

see (1.27) where the positive integer $l$ has to be now replaced by $m$. The latter mapping determines another homomorphism $X(g_n) \rightarrow A_m$. Using it, we turn the vector space
$U \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n)$ of the $X(\mathfrak{g}_n)$-module $\mathcal{E}_m^z(U)$ to another $X(\mathfrak{g}_n)$-module, to be denoted by $\tilde{\mathcal{E}}_m^z(U)$. Further, define an action of the Lie algebra $\mathfrak{gl}_m$ on $\tilde{\mathcal{E}}_m^z(U)$ by pulling its action on $\mathcal{E}_m^z(U)$ back through the automorphism

$$E_{ab} \mapsto -\delta_{ab} n/2 + E_{ab} \quad \text{for} \quad a, b = 1, \ldots, m. \quad (2.22)$$

Thus the action of $\mathfrak{gl}_m$ on $\tilde{\mathcal{E}}_m^z(U)$ is determined by the composition of homomorphisms

$$U(\mathfrak{gl}_m) \to U(\mathfrak{gl}_m) \to \text{End}(U \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n)),$$

where the first map is the automorphism (2.22) while the second map corresponds to the natural action of $\mathfrak{gl}_m$ on $\mathcal{E}_m^z(U)$. The following proposition is a particular case of Theorem 3.1 from the next section.

**Proposition 2.5.** For the $f_m$-module $V$ parabolically induced from any $\mathfrak{gl}_m$-module $U$, the bimodule $\mathcal{F}_m(V)_\tau$ of $\mathfrak{gl}_m$ and $X(\mathfrak{g}_n)$ is equivalent to $\tilde{\mathcal{E}}_m^z(U)$ where $z = \pm \frac{1}{2}$.

Further, let $u$ and $f$ range over the vector spaces $U$ and $\mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n)$ respectively. In the next section, we will show that the linear map

$$U \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n) \to (V \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n))_\tau$$

defined by mapping $u \otimes f$ to the class of $\pi \otimes f$ in the space of $\tau$-coinvariants, is an equivalence of bimodules $\tilde{\mathcal{E}}_m^z(U) \to \mathcal{F}_m(V)_\tau$ over $\mathfrak{gl}_m$ and $X(\mathfrak{g}_n)$.

An element $\mu$ of the vector space $\mathfrak{h}^*$ dual to $\mathfrak{h}$ is called a weight. A weight $\mu$ can be identified with the sequence $(\mu_1, \ldots, \mu_m)$ of its labels, where

$$\mu_a = \mu(F_{a-m-1,a-m-1}) = -\mu(F_{m-a+1,m-a+1}) \quad \text{for} \quad a = 1, \ldots, m.$$ 

The Verma module $M_\mu$ of the Lie algebra $f_m$ is the quotient of the algebra $U(f_m)$ by the left ideal generated by all elements $X \in \mathfrak{n}'$, and by all elements $X - \mu(X)$ where $X \in \mathfrak{h}$. The elements of the Lie algebra $f_m$ act on this quotient via left multiplication. The image of the identity element $1 \in U(f_m)$ in this quotient is denoted by $1_\mu$. Then $X \cdot 1_\mu = 0$ for all $X \in \mathfrak{n}'$, and $X \cdot 1_\mu = \mu(X) \cdot 1_\mu$ for all $X \in \mathfrak{h}$. Denote by $L_\mu$ be the quotient of the Verma module $M_\mu$ relative to the maximal proper submodule. This quotient is a simple $f_m$-module of the highest weight $\mu$.

For $z \in \mathbb{C}$ denote by $P_z$ the $Y(\mathfrak{gl}_n)$-module obtained by pulling the standard action of $U(\mathfrak{gl}_n)$ on $\mathcal{G}(\mathbb{C}^n)$ back through the homomorphism $Y(\mathfrak{gl}_n) \to U(\mathfrak{gl}_n)$ defined by (1.4), and then back through the automorphism $\tau_z$ of $Y(\mathfrak{gl}_n)$. Let $x_1, \ldots, x_n$ be the standard generators of $\mathcal{G}(\mathbb{C}^n)$ and let $\partial_1, \ldots, \partial_n$ be the corresponding left derivations. Using (0.3), the action of $Y(\mathfrak{gl}_n)$ on $P_z$ is determined by the homomorphism $Y(\mathfrak{gl}_n) \to \mathcal{GD}(\mathbb{C}^n)$,

$$T_{ij}(u) \mapsto \delta_{ij} + \frac{x_i \partial_j}{u + z}.$$ 

(2.23)

Using the comultiplication (1.9), for any $z_1, \ldots, z_m \in \mathbb{C}$ define the tensor product of $Y(\mathfrak{gl}_n)$-modules

$$P_{z_m} \otimes \ldots \otimes P_{z_1}. \quad (2.24)$$

For $a = 1, \ldots, m$ let $\deg_a$ be the linear operator on this tensor product, corresponding to evaluation of the total degree in $x_1, \ldots, x_n$ in the tensor factor $P_{z_a}$; that is the $a$-th
tensor factor when counting from right to left. By restricting this tensor product of \( Y(g_n) \)-modules to the subalgebra \( Y(g_n) \subset Y(g_n) \) and then using the homomorphism \( X(g_n) \to Y(g_n) \) defined by (1.18), we can regard the tensor product (2.24) as a module over the extended twisted Yangian \( X(g_n) \).

**Corollary 2.6.** The bimodule \( \mathcal{F}_m(M_\mu)_n \) over \( \mathfrak{h} \) and \( X(g_n) \) is equivalent to the tensor product

\[
P_{\mu,m+1} \otimes P_{\mu,m+2} \otimes \cdots \otimes P_{\mu,m+1}\]

(2.25)
pulled back through the automorphism of \( X(g_n) \) defined by (1.17), where \( f(u) \) equals

\[
\prod_{a=1}^m \left( 1 + \frac{1}{u - z - m + a - 1 - \mu_a} \right);
\]

here \( z = \pm \frac{1}{2} \). The element \( F_{m,a+1,m-a+1} \in \mathfrak{h} \) acts on (2.25) as the operator

\[
-n/2 + \deg a - \mu_a.
\]

**Proof.** We have an embedding of \( g_m \) to \( f_m \) such that \( E_{aa} \mapsto F_{aa} \) for \( a = 1, \ldots, m \). Then the Cartan subalgebra \( \mathfrak{t} \) of \( g_m \) is identified with the Cartan subalgebra \( \mathfrak{h} \) of \( f_m \).

Put \( \bar{a} = m - a + 1 \) for short. If we regard the weight \( \mu \) as an element of \( \mathfrak{t}^* \), then

\[
\mu(E_{\bar{a}\bar{a}}) = -\mu_a \quad \text{for} \quad a = 1, \ldots, m.
\]

Let \( U \) be the Verma module of the Lie algebra \( g_m \) corresponding to \( \mu \in \mathfrak{t}^* \). It is defined as the quotient of the algebra \( U(g_m) \) by the left ideal generated by all elements \( E_{ab} \) with \( a < b \), and by all elements \( E_{aa} - \mu(E_{aa}) \). The Verma module \( M_\mu \) of the Lie algebra \( f_m \) is then equivalent to the module \( V \) parabolically induced from the \( g_m \)-module \( U \).

Here we use the decomposition (2.19).

Let \( s \) denote the subalgebra of the Lie algebra \( g_m \) spanned by all elements \( E_{ab} \) with \( a > b \). Using our embedding of \( g_m \) to \( f_m \), we can also regard \( s \) as a subalgebra of \( f_m \). The Lie algebra \( \mathfrak{n} \) of \( f_m \) is then spanned by \( \mathfrak{r} \) and \( s \). By Proposition 2.5, the bimodule \( \mathcal{F}_m(M_\mu)_n \) over \( \mathfrak{h} \) and \( X(g_n) \) is equivalent to \( \mathcal{E}_m^z(U)_s \) where \( z = \pm \frac{1}{2} \). To describe the latter bimodule, let us firstly consider the bimodule \( \mathcal{E}_m^z(U)_s \) over \( \mathfrak{t} \) and \( Y(g_n) \). Using [KN2, Corollary 2.4], the bimodule \( \mathcal{E}_m^z(U)_s \) is equivalent to the tensor product of \( Y(g_n) \)-modules (2.25) where the element \( E_{\bar{a}\bar{a}} \in \mathfrak{t} \) acts as \( \deg a - \mu_a \). After pulling the action of Lie algebra \( g_m \) on \( \mathcal{E}_m^z(U) \) back through the automorphism (2.22), the element \( E_{\bar{a}\bar{a}} \in \mathfrak{t} \) will act on the tensor product of vector spaces (2.25) as (2.27).

To complete the proof of Corollary 2.6, recall that the action of \( X(g_n) \) on \( \mathcal{E}_m^z(U) \) differs from that on \( \mathcal{E}_m^z(U) \) by multiplying the series (2.20) by (2.21). Using (1.28), the series \( 1 + Z(u - z - m) \) in \( u^{-1} \) with the coefficients in \( \mathbb{Z}(g_m) \) acts on the Verma module \( U \) via scalar multiplication by the series (2.26). \( \square \)

By definition, the vector spaces of the two equivalent bimodules in Corollary 2.6 are \( (M_\mu \otimes \mathcal{G}(C^m \otimes C^n))_n \) and \( \mathcal{G}(C^n)_{\otimes m} \) respectively. We can determine a linear map from the latter vector space to the former one, by mapping \( f_1 \otimes \cdots \otimes f_m \) to the class of the element \( 1_\mu \otimes f \) in the space of \( n \)-coinvariants. Here for any \( m \) polynomials \( f_1, \ldots, f_m \) in
the \( n \) anticommuting variables \( x_1, \ldots, x_n \) the polynomial \( f \) in the \( mn \) anticommuting variables \( x_{11}, \ldots, x_{mn} \) is defined by setting
\[
f(x_{11}, \ldots, x_{mn}) = f_1(x_{11}, \ldots, x_{1n}) \cdots f_m(x_{m1}, \ldots, x_{mn}).
\]
(2.28)

This provides the bimodule equivalence in Corollary 2.6, see [KN2, Corollary 2.4] and the remarks made immediately after stating Proposition 2.5 here.

For any \( z \in \mathbb{C} \) denote by \( P'_z \) the \( Y(\mathfrak{gl}_n) \)-module obtained by pulling \( P_z \) back through the automorphism (1.11) of \( Y(\mathfrak{gl}_n) \). According to (2.23), the action of \( Y(\mathfrak{gl}_n) \) on \( P'_z \) is determined by the homomorphism \( Y(\mathfrak{gl}_n) \to G\mathcal{D}(\mathbb{C}^n) \),
\[
T_{ij}(u) \mapsto \delta_{ij} - \frac{\theta_i \theta_j x_j \partial_i}{u - z}.
\]
(2.29)

**Lemma 2.7.** The \( Y(\mathfrak{gl}_n) \)-module \( P'_z \) can also be obtained by pushing the action of \( Y(\mathfrak{gl}_n) \) on \( P_{-z-1} \) forward through the automorphism of \( G\mathcal{D}(\mathbb{C}^n) \) such that for each \( i = 1, \ldots, n \)
\[
x_i \mapsto \theta_i \partial_i \quad \text{and} \quad \partial_i \mapsto \theta_i x_i,
\]
(2.30)
and by pulling the resulting action back through the automorphism (1.3) of \( Y(\mathfrak{gl}_n) \) where
\[
g(u) = 1 - \frac{1}{u - z}.
\]
(2.31)

Thus the action of \( Y(\mathfrak{gl}_n) \) on \( P'_z \) can also be determined by the composition
\[
Y(\mathfrak{gl}_n) \to Y(\mathfrak{gl}_n) \xrightarrow{\tau_{-z-1}} Y(\mathfrak{gl}_n) \to U(\mathfrak{gl}_n) \to G\mathcal{D}(\mathbb{C}^n) \to G\mathcal{D}(\mathbb{C}^n).
\]

Here the first map is the automorphism (1.3) of \( Y(\mathfrak{gl}_n) \) where the series \( g(u) \) is given by (2.31), the last map is the automorphism (2.30) of \( G\mathcal{D}(\mathbb{C}^n) \), while the other three maps are defined like in (0.3).

**Proof.** Applying the automorphism (2.30) to the right hand side of (2.23) and replacing the parameter \( z \) there by \( -z - 1 \) we get
\[
delta_{ij} + \frac{\theta_i \theta_j x_j \partial_i}{u - z - 1} = \delta_{ij} + \frac{\delta_{ij} - \theta_i \theta_j x_j \partial_i}{u - z - 1} = \frac{u - z}{u - z - 1} \left( \delta_{ij} - \frac{\theta_i \theta_j x_j \partial_i}{u - z} \right)
\]
which, after multiplying it by (2.31), becomes the right hand side of (2.29). \( \square \)

**3. Parabolic induction**

The twisted Yangian \( Y(\mathfrak{g}_n) \) is not just a subalgebra of \( Y(\mathfrak{gl}_n) \), it is also a right coideal of the coalgebra \( Y(\mathfrak{gl}_n) \) relative to the comultiplication (1.9). Indeed, let us apply this comultiplication to the \( i,j \) entry of the \( n \times n \) matrix \( T'(-u)T(u) \). We get the sum
\[
\sum_{k=1}^{n} \theta_i \theta_k \Delta(T_{kj}(-u)T_{kj}(u)) =
\]
\[
\sum_{g, h, k=1}^{n} \theta_i \theta_j (T_{\tilde{k} \tilde{g}}(-u) \otimes T_{\tilde{g} \tilde{i}}(-u)) (T_{kh}(u) \otimes T_{hj}(u)) = \\
\sum_{g, h, k=1}^{n} \theta_g \theta_k T_{\tilde{k} \tilde{g}}(-u) T_{kh}(u) \otimes \theta_i \theta_j T_{\tilde{g} \tilde{i}}(-u) T_{hj}(u).
\]

In the last displayed line, by performing the summation over \(k = 1, \ldots, n\) in the first tensor factor we get the \(g, h\) entry of the matrix \(T'(-u) T(u)\). Therefore

\[
\Delta(Y(\mathfrak{g}_n)) \subset Y(\mathfrak{g}_n) \otimes Y(\mathfrak{gl}_n).
\]

For the extended twisted Yangian \(X(\mathfrak{g}_n)\), one can define a homomorphism of associative algebras

\[
X(\mathfrak{g}_n) \to X(\mathfrak{g}_n) \otimes Y(\mathfrak{gl}_n)
\]

by assigning

\[
S_{ij}(u) \mapsto \sum_{g, h=1}^{n} S_{gh}(u) \otimes \theta_i \theta_j T_{\tilde{g} \tilde{i}}(-u) T_{hj}(u).
\] (3.1)

The homomorphism property can be verified directly, see [KN3, Section 3]. Using the homomorphism (3.1), the tensor product of any modules over the algebras \(X(\mathfrak{g}_n)\) and \(Y(\mathfrak{gl}_n)\) becomes another module over \(X(\mathfrak{g}_n)\).

Furthermore, the homomorphism (3.1) is a coaction of the Hopf algebra \(Y(\mathfrak{gl}_n)\) on the algebra \(X(\mathfrak{g}_n)\). Formally, one can define a homomorphism of associative algebras

\[
X(\mathfrak{g}_n) \to X(\mathfrak{g}_n) \otimes Y(\mathfrak{gl}_n) \otimes Y(\mathfrak{gl}_n)
\]

in two different ways: either by using the assignment (3.1) twice, or by using (3.1) and then (1.9). Both ways however lead to the same result, see again [KN3, Section 3].

Now for any positive integer \(l\) consider the general linear Lie algebra \(\mathfrak{gl}_{2m+2l}\) and its subalgebra \(\mathfrak{f}_{m+l}\). This subalgebra is spanned by the elements \(F_{ab}\) where \(a, b = -m - l, \ldots, -1, 1, \ldots, m + l\).

(3.2)

Extend the notation (2.1) and (2.2) to all these indices \(a, b\). Now identify \(\mathfrak{f}_m\) with the subalgebra of \(\mathfrak{f}_{m+l}\) spanned by the elements \(F_{ab}\) where \(a, b = -m, \ldots, -1, 1, \ldots, m\). Choose the embedding of the Lie algebra \(\mathfrak{gl}_l\) to \(\mathfrak{f}_{m+l}\) determined by the mappings

\[
E_{ab} \mapsto F_{m+a,m+b} \quad \text{for} \quad a, b = 1, \ldots, l.
\] (3.3)

Let \(\mathfrak{q}, \mathfrak{q}'\) be the subalgebras of \(\mathfrak{f}_{m+l}\) spanned respectively by the elements \(F_{ab}, F_{ba}\) where

\[
a = m + 1, \ldots, m + l \quad \text{and} \quad b = -m - l, \ldots, -1, 1, \ldots, m;
\]

these two subalgebras of \(\mathfrak{f}_{m+l}\) are nilpotent. Put \(\mathfrak{p} = \mathfrak{f}_m \oplus \mathfrak{gl}_l \oplus \mathfrak{q}'\). Then \(\mathfrak{p}\) is a maximal parabolic subalgebra of the reductive Lie algebra \(\mathfrak{f}_{m+l}\), and \(\mathfrak{f}_{m+l} = \mathfrak{q} \oplus \mathfrak{p}\). We do not exclude the case \(m = 0\) here. In this case the nilpotent subalgebras \(\mathfrak{q}\) and \(\mathfrak{q}'\) of \(\mathfrak{f}_{m+l}\) become the Abelian subalgebras \(\mathfrak{r}\) and \(\mathfrak{r}'\) of the Lie algebra \(\mathfrak{f}_{l}\); see the decomposition
Let \( V \) and \( U \) be any modules of the Lie algebras \( f_m \) and \( \mathfrak{gl}_l \) respectively. Denote by \( V \otimes U \) the \( f_{m+l} \)-module \textit{parabolically induced} from the \( f_m \oplus \mathfrak{gl}_l \)-module \( V \otimes U \). To define \( V \otimes U \), one first extends the action of the Lie algebra \( f_m \oplus \mathfrak{gl}_l \) on \( V \otimes U \) to the Lie algebra \( \mathfrak{p} \), so that every element of the subalgebra \( \mathfrak{q}' \subset \mathfrak{p} \) acts on \( V \otimes U \) as zero. By definition, \( V \otimes U \) is the \( f_{m+l} \)-module induced from the \( \mathfrak{p} \)-module \( V \otimes U \). Note that here we have a canonical embedding \( V \otimes U \rightarrow V \otimes U \) of \( \mathfrak{p} \)-modules; we will denote by \( v \otimes u \) the image of an element \( v \otimes u \in V \otimes U \) under this embedding.

Consider the bimodule \( F_{m+l}(V \otimes U) \) over \( f_{m+l} \) and \( X(\mathfrak{g}_n) \). Here the action of \( X(\mathfrak{gl}_n) \) commutes with the action of the Lie algebra \( f_{m+l} \), and hence with the action of the subalgebra \( \mathfrak{q} \subset f_{m+l} \). Therefore the vector space \( F_{m+l}(V \otimes U)_{\mathfrak{q}} \) of coinvariants of the action of the subalgebra \( \mathfrak{q} \) is a quotient of the \( X(\mathfrak{g}_n) \)-module \( F_{m+l}(V \otimes U) \). Note that the subalgebra \( f_m \oplus \mathfrak{gl}_l \subset f_{m+l} \) also acts on this quotient.

For any \( z \in \mathbb{C} \) consider the bimodule \( \mathcal{E}_l^z(U) \) over \( \mathfrak{gl}_l \) and \( Y(\mathfrak{g}_n) \) defined as in the end of Section 1. Also consider the bimodule \( F_m(V) \) over \( f_m \) and \( X(\mathfrak{g}_n) \). Using the homomorphism \( \mathcal{E}_l^z(U) \), the tensor product of vector spaces \( F_m(V) \otimes \mathcal{E}_l^z(U) \) becomes a module over \( X(\mathfrak{g}_n) \). This module is determined by the homomorphism \( X(\mathfrak{g}_n) \rightarrow B_m \otimes A_l \) such that for any \( i,j=1,\ldots,n \) the series \( S_{ij}(u) \) is mapped to

\[
\sum_{g,h=1}^n \beta_m(S_g(u)) \otimes \theta_i \theta_g \alpha_l(T_{g,i}(-u+z) T_{h,j}(u+z)).
\]  

(3.4)

Let us now map the series \( S_{ij}(u) \) to the series \( (1 \otimes 1) \otimes (1 + Z(u - z - l)) \otimes 1 \) in \( B_m \otimes A_l [[u^{-1}]] \),

\[
(1 \otimes 1) \otimes (1 + Z(u - z - l)) \otimes 1 \in B_m \otimes A_l [[u^{-1}]],
\]  

(3.5)

see (1.27). This mapping determines another homomorphism \( X(\mathfrak{g}_n) \rightarrow B_m \otimes A_l \). Using it, we turn the vector space of the \( X(\mathfrak{g}_n) \)-module \( F_m(V) \otimes \mathcal{E}_l^z(U) \) to yet another \( X(\mathfrak{g}_n) \)-module, which will be denoted by \( F_m(V) \otimes \mathcal{E}_l^z(U) \). Define an action of the Lie algebra \( \mathfrak{gl}_l \) on the latter \( X(\mathfrak{g}_n) \)-module by pulling the action of \( \mathfrak{gl}_l \) on \( \mathcal{E}_l^z(U) \) back through the automorphism

\[
E_{ab} \mapsto -\delta_{ab} n/2 + E_{ab} \quad \text{for} \quad a,b=1,\ldots,l.
\]  

(3.6)

The Lie algebra \( f_m \) acts on the \( X(\mathfrak{g}_n) \)-module \( F_m(V) \otimes \mathcal{E}_l^z(U) \) via the tensor factor \( F_m(V) \). Thus \( F_m(V) \otimes \mathcal{E}_l^z(U) \) becomes a bimodule over the direct sum of Lie algebras \( f_m \oplus \mathfrak{gl}_l \) and over the extended twisted Yangian \( X(\mathfrak{g}_n) \). In the case \( m=0 \) the next theorem becomes Proposition 2.5, where the positive integer \( m \) has to be replaced by \( l \). Here we assume that \( F_0(V) = \mathbb{C} \) so that \( \beta_0(S_{ij}(u)) = \delta_{ij} \).

**Theorem 3.1.** The bimodule \( F_{m+l}(V \otimes U)_{\mathfrak{q}} \) over \( f_m \oplus \mathfrak{gl}_l \) and \( X(\mathfrak{g}_n) \) is equivalent to \( F_m(V) \otimes \mathcal{E}_l^z(U) \) where \( z = m + \frac{1}{2} \).

**Proof.** In the remainder of this section we shall prove Theorem 3.1. As vector spaces,

\[
F_{m+l}(V \otimes U)_{\mathfrak{q}} = (V \otimes U \otimes \mathcal{G}(\mathbb{C}^{m+l} \otimes \mathbb{C}^n))_{\mathfrak{q}},
\]

\[
F_m(V) \otimes \mathcal{E}_l^z(U) = V \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n) \otimes U \otimes \mathcal{G}(\mathbb{C}^l \otimes \mathbb{C}^n).
\]
We can determine a linear map from the latter vector space to the former one by mapping any element \( v \otimes f \otimes u \otimes g \) to the class of \( v \otimes u \otimes f \otimes g \) in the space of \( q \)-coinvarians. Here \( v \in V, f \in \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n) \) and \( u \in U, g \in \mathcal{G}(\mathbb{C}^l \otimes \mathbb{C}^n) \) whereas the tensor product \( f \otimes g \) is identified with an element of \( \mathcal{G}(\mathbb{C}^{m+l} \otimes \mathbb{C}^n) \) in a natural way, which corresponds to the decomposition

\[
\mathbb{C}^{m+l} \otimes \mathbb{C}^n = \mathbb{C}^m \otimes \mathbb{C}^n \oplus \mathbb{C}^l \otimes \mathbb{C}^n. \tag{3.7}
\]

We will show that this map establishes an equivalence of bimodules in Theorem 3.1.

The vector space of the \( f_{m+l} \)-module \( V \otimes U \) can be identified with the tensor product \( U(q) \otimes V \otimes U \) where the Lie subalgebra \( q \subset f_{m+l} \) acts via left multiplication on the first tensor factor. Then \( v \otimes u = 1 \otimes v \otimes u \), so that the tensor product \( V \otimes U \) gets identified with the subspace

\[
1 \otimes V \otimes U \subset U(q) \otimes V \otimes U. \tag{3.8}
\]

On this subspace, every element of the subalgebra \( q' \subset f_{m+l} \) acts as zero, while the two direct summands of subalgebra \( f_m \oplus gl_l \subset f_{m+l} \) act non-trivially only on the tensor factors \( V \) and \( U \) respectively. All this determines the action of Lie algebra \( f_{m+l} \) on \( U(q) \otimes V \otimes U \). Now consider \( F_{m+l}(V \otimes U) \) as a \( f_{m+l} \)-module, we will denote it by \( M \) for short. Then \( M \) is the tensor product of two \( f_{m+l} \)-modules,

\[
M = (V \otimes U) \otimes \mathcal{G}(\mathbb{C}^{m+l} \otimes \mathbb{C}^n) = U(q) \otimes V \otimes U \otimes \mathcal{G}(\mathbb{C}^{m+l} \otimes \mathbb{C}^n). \tag{3.9}
\]

The vector spaces of the \( X(gl_n) \)-module \( F_m(V) \) and of the \( Y(gl_n) \)-module \( \mathcal{E}_l(U) \) are respectively \( V \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n) \) and \( U \otimes \mathcal{G}(\mathbb{C}^l \otimes \mathbb{C}^n) \). The action of the Lie algebra \( f_m \) on the first vector space is defined by (2.6). By pulling back through the automorphism (3.6), the action of the Lie algebra \( gl_l \) on the second vector space is defined by mapping

\[
E_{ab} \mapsto -\delta_{ab} n/2 + E_{ab} \otimes 1 + \sum_{k=1}^n 1 \otimes x_{ak} \partial_{bk} \quad \text{for} \quad a, b = 1, \ldots, l.
\]

Identify the tensor product of these two vector spaces with the vector space

\[
V \otimes U \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n) \otimes \mathcal{G}(\mathbb{C}^l \otimes \mathbb{C}^n) = V \otimes U \otimes \mathcal{G}(\mathbb{C}^{m+l} \otimes \mathbb{C}^n) \tag{3.10}
\]

where we use the direct sum decomposition (3.7). We get an action of the direct sum of Lie algebras \( f_m \oplus gl_l \) on the vector space (3.10).

Let us now define a linear map

\[
\chi : V \otimes U \otimes \mathcal{G}(\mathbb{C}^{m+l} \otimes \mathbb{C}^n) \to M \big/ q \cdot M
\]

by the assignment

\[
\chi : y \otimes x \otimes t \mapsto 1 \otimes y \otimes x \otimes t + q \cdot M
\]

for any vectors \( y \in V, x \in U \) and \( t \in \mathcal{G}(\mathbb{C}^{m+l} \otimes \mathbb{C}^n) \). The operator \( \chi \) intertwines the actions of the Lie algebra \( f_m \oplus gl_l \); see the definition (2.6) where \( m \) is to be replaced by \( m + l \). Let us demonstrate that the operator \( \chi \) is bijective.

Firstly consider the action of the Lie subalgebra \( q \subset f_{m+l} \) on the vector space

\[
\mathcal{G}(\mathbb{C}^{m+l}) = \mathcal{G}(\mathbb{C}^m) \otimes \mathcal{G}(\mathbb{C}^l);
\]
the action is defined by (2.6) where \( n = 1 \), and the integer \( m \) is replaced by \( m + l \). This vector space admits a descending filtration by the subspaces

\[
\bigoplus_{K=N}^{l} \mathcal{G}(\mathbb{C}^m) \otimes \mathcal{G}^K(\mathbb{C}^l) \quad \text{where} \quad N = 0, 1, \ldots, l.
\]

Here \( \mathcal{G}^K(\mathbb{C}^l) \) stands for the homogeneous subspace of \( \mathcal{G}(\mathbb{C}^l) \) of degree \( K \). The action of the Lie algebra \( \mathfrak{q} \) on \( \mathcal{G}(\mathbb{C}^{m+l}) \) preserves each of the filtration subspaces, and becomes trivial on the associated graded space.

Similarly, for any \( n = 1, 2, \ldots \) the vector space \( \mathcal{G}(\mathbb{C}^{m+l} \otimes \mathbb{C}^n) \) admits an descending filtration by \( \mathfrak{q} \)-submodules such that \( \mathfrak{q} \) acts trivially on each of the corresponding graded subspaces. The latter filtration induces a filtration of \( M \) by \( \mathfrak{q} \)-submodules such that on the corresponding graded quotient \( \text{gr} M \), the Lie algebra \( \mathfrak{q} \) acts via left multiplication on the first tensor factor \( \mathfrak{u}(\mathfrak{q}) \) in (3.9). The space \( V \otimes \mathfrak{u} \otimes \mathcal{G}(\mathbb{C}^{m+l} \otimes \mathbb{C}^n) \) is therefore isomorphic to the space of coinvariants \( (\text{gr} M)_\mathfrak{q} \) via the bijective linear map

\[
y \otimes x \otimes t \mapsto 1 \otimes y \otimes x \otimes t + \mathfrak{q} \cdot (\text{gr} M).
\]

Therefore the linear map \( \chi \) is bijective as well. It now remains to show that the map \( \chi \) intertwines the actions of the algebra \( \mathcal{X}(\mathfrak{g}_n) \).

In this section we will use the symbol \( \equiv \) to indicate equalities in the algebra \( \mathfrak{u}(\mathfrak{f}_{m+l}) \) modulo the left ideal generated by the elements of the subalgebra \( \mathfrak{q}' \subset \mathfrak{f}_{m+l} \). Any two elements of \( \mathfrak{u}(\mathfrak{f}_{m+l}) \) related by \( \equiv \) act on the subspace (3.8) in the same way. We will extend the relation \( \equiv \) to formal power series in \( u^{-1} \) with coefficients in \( \mathfrak{u}(\mathfrak{f}_{m+l}) \), and then to matrices whose entries are these series. Put

\[
v = u \pm \frac{1}{2} - m - l \quad \text{and} \quad w = -u \pm \frac{1}{2} - m - l.
\]

The definition of the \( \mathcal{X}(\mathfrak{g}_n) \)-module \( M \) involves the \( (2m + 2l) \times (2m + 2l) \) matrix whose \( a, b \) entry is \( \delta_{ab} v + F_{ab} \). The rows and columns of this matrix are labelled by the indices (3.2). We proved in [KN3, Section 3] that the inverse to this matrix is related by \( \equiv \) to the block matrix

\[
\begin{bmatrix}
H & 0 & 0 \\
I & J & 0 \\
P & Q & R
\end{bmatrix}
\]

(3.12)

where the blocks \( H, P, R \) are certain matrices of size \( l \times l \) while the blocks \( I, J, Q \) are certain matrices of sizes \( 2m \times l, 2m \times 2m, l \times 2m \) respectively. Let us label the rows and columns of the blocks by the same indices as in the compound matrix (3.12). For instance, the rows and columns of the \( l \times l \) matrix \( R \) are labelled by \( m + 1, \ldots, m + l \).

Keeping to the notation of Section 2, let \( F \) be the \( 2m \times 2m \) matrix whose \( c, d \) entry is \( F_{cd} \) for \( c, d = -m, \ldots, -1, 1, \ldots, m \). Let \( F(u) \) be the inverse to the matrix \( u + F \). The entries of the matrix \( F(u) \) are formal power series in \( u^{-1} \) with coefficients in the algebra \( \mathfrak{u}(\mathfrak{f}_m) \), see (2.4). But now the algebra \( \mathfrak{u}(\mathfrak{f}_m) \) is regarded as a subalgebra of \( \mathfrak{u}(\mathfrak{f}_{m+l}) \). Let us denote by \( W(u) \) the trace of the matrix \( F(u) \), as we did in Section 2.

Denote by \( E \) the \( l \times l \) matrix whose \( a, b \) entry is \( E_{ab} \) for \( a, b = m + 1, \ldots, m + l \). Using our embedding (3.3) of the Lie algebra \( \mathfrak{gl}_l \) to \( \mathfrak{f}_{m+l} \), this notation agrees with the notation of Section 1. But now we use the indices \( a, b = m + 1, \ldots, m + l \) to label the rows and columns of the matrix \( E \). Let \( E(v) \) the inverse to the matrix \( v + E \). Let
$E_{ab}(u)$ be the $a,b$ entry of the inverse matrix. Let $Z(v)$ be the trace of the inverse matrix. The coefficients of the formal power series $Z(v)$ in $v^{-1}$ belong to the centre of the algebra $U(\mathfrak{g}_l)$, which is now regarded as a subalgebra of $U(f_{m+l})$. Further, for any indices $a,b = m + 1, \ldots, m + l$ denote $\tilde{E}_{ab}(v) = (v + l + E')_{ba}^{-1}$. Then by Lemma 1.3

$$
(1 + Z(v)) \tilde{E}_{ab}(v) = E_{ab}(v). \quad (3.13)
$$

Let $a,b = m + 1, \ldots, m + l$ and $c,d = -m, \ldots, -1,1, \ldots, m$. By [KN3, Section 3]

$$
-H_{-b,-a} = (1 + Z(v)) \left((W(v + l) + \frac{1}{2u} + 1) \tilde{E}_{ab}(w) \pm \frac{1}{2u} \tilde{E}_{ab}(v)\right),
$$

$$
-I_{-d,-a} = \sum_{b > m > c > -m} \varepsilon_{ad} F_{bc} (1 + Z(v)) \left(\varepsilon_{cd} \tilde{E}_{ab}(w) F_{-d,-c}(v + l) \pm \frac{\tilde{E}_{ab}(w) - \tilde{E}_{ab}(v)}{2u} F_{cd}(v + l)\right),
$$

$$
J_{cd} = (1 + Z(v)) F_{cd}(v + l),
$$

$$
P_{b,-a} = \sum_{e,f > m} F_{f,-e} E_{bf}(v) \tilde{E}_{ae}(w) \pm \sum_{e,f > m, m > c, d > -m} \varepsilon_{ad} F_{f,-d} F_{ec} E_{be}(v) \tilde{E}_{af}(w) F_{cd}(v + l),
$$

$$
-Q_{ad} = \sum_{e > m > c > -m} F_{ec} E_{ae}(v) F_{cd}(v + l), \quad R_{ab} = E_{ab}(v).
$$

By definition of $X(\mathfrak{g}_n)$-module $M$, the action of $X(\mathfrak{g}_n)$ on the elements of the subspace

$$
1 \otimes V \otimes U \otimes \mathcal{G}((\mathbb{C}^{m+l} \otimes \mathbb{C}^n) \subset M \quad (3.14)
$$

can be now described by assigning to every series $S_{ij}(u)$ the following sum of series with coefficients in the algebra $B_{m+l} = U(f_{m+l}) \otimes \mathcal{GD}(\mathbb{C}^{m+l} \otimes \mathbb{C}^n)$:

$$
\delta_{ij} + \sum_{a,b > m} R_{ab} \otimes \theta_i \theta_j \partial_{a_i} x_{b_j} + \sum_{a,b > m} H_{-b,-a} \otimes x_{b_i} \partial_{a_j} + \sum_{a > m, d > 0} \left((I_{-d,-a} \otimes x_{d_i} \partial_{a_j} + I_{d,-a} \otimes \theta_i \partial_{d_i} \partial_{a_j}) + \sum_{m > c, d > 0} (J_{-c,d} \otimes x_{ci} \partial_{d_j} + J_{-c,d} \otimes \theta_j x_{ci} x_{d_j} + J_{c,-d} \otimes \theta_i \partial_{ci} \partial_{d_j} + J_{cd} \otimes \theta_i \theta_j \partial_{ci} x_{d_j})
$$

$$
+ \sum_{a,e > m} P_{e,-a} \otimes \theta_i \partial_{e_i} \partial_{a_j} + \sum_{a > m, d > 0} (Q_{a,-d} \otimes \theta_i \partial_{a_i} \partial_{d_j} + Q_{ad} \otimes \theta_i \theta_j \partial_{a_i} x_{d_j}). \quad (3.15)
$$
Here for $a = 1, \ldots, m + l$ and $i = 1, \ldots, n$ we use the standard generators $x_{ai}$ of the Grassmann algebra $G(\mathbb{C}^{m+l} \otimes \mathbb{C}^n)$. Then $\partial_{ai}$ is the left derivation on $G(\mathbb{C}^{m+l} \otimes \mathbb{C}^n)$ relative to $x_{ai}$. The generators $x_{ai}$ with $a \leq m$ and $a > m$ correspond to the first and the second direct summands in (3.7).

Consider the action of $X(\mathfrak{g}_a)$ on the elements of the subspace (3.14) modulo $q \cdot M$, using the definition (2.6) where $m$ is to be replaced by $m+l$. From now till the end of this section, we will be assuming that $a, b, c, d = m+1, \ldots, n$ while $c, d = 1, \ldots, m$. The indices $g, h$ and $k$ will run through $1, \ldots, n$.

By our description of the block $R$, the sum displayed in the first of six lines (3.15) acts on the elements of the subspace (3.14) as the sum over the indices $a, b, c, d$ of

$$\delta_{ij} + \sum_{a,b} E_{ab}(v) \otimes \theta_i \theta_j \partial_{ai} x_{bj} =$$

$$\delta_{ij} (1 + Z(v)) - \sum_{a,b} E_{ab}(v) \otimes \theta_i \theta_j x_{bj} \partial_{ai}.$$  \hspace{1cm} (3.16)

By our description of the block $H$, the sum displayed in the second of six lines (3.15) acts on the elements of (3.14) as the sum over the indices $a, b$ of

$$- (1 + Z(v)) \left( (W(v + l) \mp \frac{1}{2u} + 1) \tilde{E}_{ab}(w) \pm \frac{1}{2u} \tilde{E}_{ab}(v) \right) \otimes x_{bi} \partial_{aj}.$$  \hspace{1cm} (3.17)

By our description of the block $I$, the sum in the third of six lines (3.15) acts on the elements of (3.14) as the sum over the indices $a, b, c, d$ of

$$\mp F_{b-c} (1 + Z(v)) \left( \tilde{E}_{ab}(w) F_{d-c}(v + l) + \frac{\tilde{E}_{ab}(w) - \tilde{E}_{ab}(v)}{2u} F_{-c,d}(v + l) \right) \otimes x_{di} \partial_{aj}$$

$$- F_{bc} (1 + Z(v)) \left( \tilde{E}_{ab}(w) F_{d-c}(v + l) \pm \frac{\tilde{E}_{ab}(w) - \tilde{E}_{ab}(v)}{2u} F_{cd}(v + l) \right) \otimes x_{di} \partial_{aj}$$

$$\mp F_{b-c} (1 + Z(v)) \left( \tilde{E}_{ab}(w) F_{dc}(v + l) \pm \frac{\tilde{E}_{ab}(w) - \tilde{E}_{ab}(v)}{2u} F_{c,-d}(v + l) \right) \otimes \theta_i \partial_{di} \partial_{aj}$$

$$- F_{bc} (1 + Z(v)) \left( \tilde{E}_{ab}(w) F_{d,-c}(v + l) \mp \frac{\tilde{E}_{ab}(w) - \tilde{E}_{ab}(v)}{2u} F_{c,-d}(v + l) \right) \otimes \theta_i \partial_{di} \partial_{aj}.$$  \hspace{1cm} (3.15)

Here $F_{b-c} \in \mathfrak{q}$ and $F_{bc} \in \mathfrak{q}$. Hence modulo $q \cdot M$, the expression displayed in the latter four lines acts on the elements of (3.14) as the sum over the index $k$ of

$$\left( \pm \left( \tilde{E}_{ab}(w) F_{d,c}(v - l) + \frac{\tilde{E}_{ab}(w) - \tilde{E}_{ab}(v)}{2u} F_{-c,d}(v + l) \right) \otimes \theta_k x_{bk} x_{ck} x_{di} \partial_{aj} \right.$$

$$+ \left( (W(v + l) \mp \frac{1}{2u} + 1) \tilde{E}_{ab}(w) \pm \frac{1}{2u} \tilde{E}_{ab}(v) \right) \otimes x_{bk} \partial_{ck} x_{di} \partial_{aj}$$

$$\pm \left( \tilde{E}_{ab}(w) F_{dc}(v + l) \pm \frac{\tilde{E}_{ab}(w) - \tilde{E}_{ab}(v)}{2u} F_{c,-d}(v + l) \right) \otimes \theta_i \theta_k x_{bk} x_{ck} \partial_{di} \partial_{aj}$$

$$\left. + \left( \tilde{E}_{ab}(w) F_{d,-c}(v + l) \mp \frac{\tilde{E}_{ab}(w) - \tilde{E}_{ab}(v)}{2u} F_{c,-d}(v + l) \right) \otimes \theta_i x_{bk} \partial_{ck} \partial_{di} \partial_{aj} \right)$$
acts on the elements of (3.14) as the sum over \( c, d \)
acts on the elements of the subspace (3.14) as the sum over the indices
plus the action of the sum over the indices \( a, b, c, d, e, f \)
while the expression to be summed over \( q \) modulo \( k \) elements of the subspace (3.14) as the sum over the index \( (GD_{\bullet}) \).

Similarly, the sum over the block \( J \), the sum displayed in the fourth of six lines (3.15) acts on the elements of (3.14) as the sum over \( c, d \) of

\[
(1 + Z(v)) \otimes \left( F_{-c,-d}(v + l) \otimes x_{ci} \partial_{d} + F_{-c,d}(v + l) \otimes \theta_{j} x_{ci} \partial_{dj} \\
+ F_{c,-d}(v + l) \otimes \theta_{i} \partial_{ci} \partial_{dj} + F_{cd}(v + l) \otimes \theta_{j} \partial_{ci} x_{dj} \right). \tag{3.19}
\]

By our description of the block \( P \), the sum displayed in the fifth of six lines (3.15) acts on the elements of the subspace (3.14) as the sum over the indices \( a, b, e, f \) of

\[
F_{f,-b} E_{ef}(v) E_{ab}(w) \otimes \theta_{i} \partial_{ci} \partial_{aj}
\]
plus the action of the sum over the indices \( a, b, c, d, e, f \) of

\[
F_{fd} F_{b,-c} E_{eb}(v) E_{af}(w) F_{-c,-d}(v + l) \otimes \theta_{i} \partial_{ci} \partial_{aj}
\]
\[
\pm F_{f,-d} F_{b,-c} E_{eb}(v) E_{af}(w) F_{-c,d}(v + l) \otimes \theta_{i} \partial_{ci} \partial_{aj}
\]
\[
+ F_{fd} F_{bc} E_{eb}(v) E_{af}(w) F_{c,-d}(v + l) \otimes \theta_{i} \partial_{ci} \partial_{aj}
\]
\[
\pm F_{f,-d} F_{bc} E_{eb}(v) E_{af}(w) F_{cd}(v + l) \otimes \theta_{i} \partial_{ci} \partial_{aj}.
\]

Modulo \( q \cdot M \), here the expression to be summed over the indices \( a, b, e, f \) acts on the elements of the subspace (3.14) as the sum over the index \( k \) of

\[
- E_{ef}(v) E_{ab}(w) \otimes \theta_{i} \theta_{k} x_{f\tilde{k}} x_{bk} \partial_{ci} \partial_{aj}
\]
while the expression to be summed over \( a, b, c, d, e, f \) acts as the sum over \( g, h \) of

\[
( E_{eb}(v) E_{af}(w) \otimes 1) \left( F_{-c,-d}(v + l) \otimes \theta_{i} \theta_{g} x_{bg} x_{cg} x_{fh} \partial_{dh} \partial_{ci} \partial_{aj} \\
\pm F_{-c,d}(v + l) \otimes \theta_{i} \theta_{g} \theta_{h} x_{bg} x_{cg} x_{f\tilde{h}} x_{dh} \partial_{ci} \partial_{aj} \\
+ F_{c,-d}(v + l) \otimes \theta_{i} x_{bg} \partial_{cg} x_{fh} \partial_{dh} \partial_{ci} \partial_{aj} \\
\pm F_{cd}(v + l) \otimes \theta_{i} \theta_{h} x_{bg} \partial_{cg} x_{f\tilde{h}} x_{dh} \partial_{ci} \partial_{aj} \right).
\]

We have \( \theta_{\tilde{k}} = \pm \theta_{k} \) for \( k = 1, \ldots, n \). Using the commutation relations in the ring \( GD(\mathbb{C}^{m+l} \otimes \mathbb{C}^{n}) \), the sum over the index \( k \) above equals the sum over \( k \) of

\[
E_{ef}(v) E_{ab}(w) \otimes \theta_{i} \theta_{k} x_{f\tilde{k}} \partial_{ci} x_{bk} \partial_{aj} \tag{3.20}
\]
plus

\[
\pm \delta_{be} E_{ef}(v) E_{ab}(w) \otimes x_{f\tilde{i}} \partial_{aj} \tag{3.21}
\]

Similarly, the sum over the indices \( g, h \) equals the sum over \( g, h \) of

\[
( F_{-c,-d}(v + l) \otimes x_{cg} \partial_{dh} + F_{-c,d}(v + l) \otimes \theta_{h} x_{cg} x_{d} + \\
F_{c,-d}(v + l) \otimes \theta_{g} \partial_{cg} \partial_{dh} + F_{cd}(v + l) \otimes \theta_{g} \theta_{h} \partial_{cg} x_{d} ) \times
\]
\[
\times \left( (1 + Z(v)) \otimes 1 \right). \tag{3.18}
\]
\[
( E_{eb}(v) \otimes \theta_i \theta_g x_{b\bar{g}} \partial_{e\bar{i}} ) \left( \tilde{E}_{af}(w) \otimes x_{fh} \partial_{a_j} \right) \tag{3.22}
\]

plus the sum over \( k \) of

\[
( \delta_{ef} E_{eb}(v) \tilde{E}_{af}(w) \otimes 1 ) \times \\
( - F_{-c,-d}(v+l) \otimes \theta_i \theta_k x_{b\bar{k}} x_{ck} \partial_{a\bar{i}} \partial_{a_j} + F_{-c,d}(v+l) \otimes \theta_k x_{b\bar{k}} x_{ck} x_{di} \partial_{a_j} \\
- F_{c,-d}(v+l) \otimes \theta_i x_{bk} \partial_{ck} \partial_{a\bar{i}} \partial_{a_j} \mp F_{cd}(v+l) \otimes x_{bk} \partial_{ck} x_{di} \partial_{a_j} ) . \tag{3.23}
\]

By our description of the block \( Q \), the sum displayed in the last of the six lines (3.15) acts on the elements of (3.14) as the sum over \( a, b, c, d \) of

\[
- ( F_{b,-c} E_{ab}(v) F_{-c,-d}(v+l) + F_{bc} E_{ab}(v) F_{c,-d}(v+l) ) \otimes \theta_i \partial_{a\bar{i}} \partial_{dj} \\
- ( F_{b,-c} E_{ab}(v) F_{-c,d}(v+l) + F_{bc} E_{ab}(v) F_{cd}(v+l) ) \otimes \theta_i \theta_j \partial_{a\bar{i}} x_{dj} .
\]

Modulo \( q \cdot M \), the expression in the above two lines acts on the elements of the subspace (3.14) as the sum over \( k \) of

\[
( E_{ab}(v) \otimes 1 ) \times \\
( F_{-c,-d}(v+l) \otimes \theta_i \theta_k x_{b\bar{k}} x_{ck} \partial_{a\bar{i}} \partial_{dj} + F_{c,-d}(v+l) \otimes \theta_i x_{bk} \partial_{ck} \partial_{a\bar{i}} \partial_{dj} + \\
F_{-c,d}(v+l) \otimes \theta_k x_{b\bar{k}} x_{ck} \theta_i \partial_{a\bar{i}} x_{dj} + F_{cd}(v+l) \otimes x_{bk} \partial_{ck} \theta_i \theta_j \partial_{a\bar{i}} x_{dj} ) . \tag{3.24}
\]

Note that this sum over the index \( k \) can be rewritten as the sum over \( k \) of

\[
( F_{-c,-d}(v+l) \otimes x_{ck} \partial_{dj} + F_{-c,d}(v+l) \otimes \theta_j x_{ck} x_{dj} + \\
F_{c,-d}(v+l) \otimes \theta_k \partial_{ck} \partial_{dj} + F_{cd}(v+l) \otimes \theta_k \theta_j \partial_{ck} x_{dj} ) \times \\
( - E_{ab}(v) \otimes \theta_i \theta_k x_{b\bar{k}} \partial_{a\bar{i}} ) . \tag{3.24}
\]

Consider the sum of the expressions (3.23) over the running indices \( e, f \). Add this sum to the expression displayed in the five lines (3.18). Using the relation

\[
\sum_{e} \tilde{E}_{eb}(v) \tilde{E}_{ae}(w) = \frac{\tilde{E}_{ab}(w) - \tilde{E}_{ab}(v)}{2u} \tag{3.25}
\]

together with (3.13) and performing cancellations, we get the expression

\[
( \pm F_{-d,c}(v+l) \otimes \theta_k x_{b\bar{k}} x_{ck} x_{di} \partial_{a_j} + F_{-d,-c}(v+l) \otimes x_{bk} \partial_{ck} x_{di} \partial_{a_j} + \\
F_{d,-c}(v+l) \otimes \theta_i x_{bk} \partial_{ck} \partial_{di} \partial_{a_j} \mp F_{dc}(v+l) \otimes \theta_i \theta_k x_{b\bar{k}} x_{ck} x_{di} \partial_{a_j} ) \times \\
( (1 + Z(v)) \tilde{E}_{ab}(w) \otimes 1 ) .
\]

After exchanging the running indices \( c \) and \( d \), the sum over the index \( k \) of the expressions in the last three displayed lines can be rewritten as

\[
\delta_{cd} (1 + Z(v)) ( F_{-c,-d}(v+l) + F_{cd}(v+l) ) \tilde{E}_{ab}(w) \otimes x_{bi} \partial_{a_j} \tag{3.26}
\]
By adding the resulting sum to the expression (3.17) we get
\[ g, h \]

and then adding the result to the last displayed expression, we get
\[ \text{due to (3.13) and (3.25). By performing the summation in (3.26) over the running indices } c, d \text{ the total can be written as the sum over indices } c, d \]
\[ \text{and then add the two resulting sums to (3.16). By using the relation (3.13) once again, the total can be written as the sum over the index } k \]
\[ \text{and then take their total. By exchanging the running indices } b \text{ and } f \text{ in (3.22), and by replacing the running index } k \text{ in (3.24),(3.27) by } g, h \text{ respectively, the total can be written as the sum over indices } c, d \text{ and } g, h \text{ of} \]
\[ \left( (1 + Z(v)) \otimes 1 \right) \times \]
\[ \left( F_{c,-d}(v + l) \otimes x_{cg} \partial_{dh} + F_{c,d}(v + l) \otimes \theta_h x_{cg} x_{dh} + \right. \]
\[ F_{c,-d}(v + l) \otimes \theta_i x_{ci} \partial_{dk} + F_{c,d}(v + l) \otimes \theta_i \theta_k x_{ci} x_{dk} \right) \times \]
\[ \left( \delta_{tg} - \sum_{e,f} \tilde{E}_{ef}(v) \otimes \theta_i \theta_g x_{f\bar{g}} \partial_{e\bar{i}} \right) \left( \delta_{hj} - \sum_{a,b} \tilde{E}_{ab}(w) \otimes x_{bh} \partial_{aj} \right). \]  

(3.28)

Let us perform the summation in (3.21) over the running indices } b, e \text{. Then let us replace the running index } f \text{ by the index } b, \text{ which becomes free after the summation. By adding the resulting sum to the expression (3.17) we get}
\[ - (1 + Z(v)) (W(v + l) + 1) \tilde{E}_{ab}(w) \otimes x_{bi} \partial_{aj} \]
due to (3.13) and (3.25). By performing the summation in (3.26) over the running indices } c, d \text{ and then adding the result to the last displayed expression, we get}
\[ - (1 + Z(v)) \tilde{E}_{ab}(w) \otimes x_{bi} \partial_{aj}. \]

(3.29)

Now do the summation over all running indices in the two expressions (3.20),(3.29) and then add the two resulting sums to (3.16). By using the relation (3.13) once again, the total can be written as the sum over the index } k \text{ of}
\[ \left( (1 + Z(v)) \otimes 1 \right) \times \]
\[ \left( \delta_{ik} - \sum_{e,f} \tilde{E}_{ef}(v) \otimes \theta_i \theta_k x_{f\bar{k}} \partial_{e\bar{i}} \right) \left( \delta_{kj} - \sum_{a,b} \tilde{E}_{ab}(w) \otimes x_{bk} \partial_{aj} \right). \]  

(3.30)

By using the definition of the series } \tilde{E}_{ab}(v) \text{ as given before the relation (3.13),
\[ \tilde{E}_{ef}(v) = (v + l + E')^{-1}_{fe} = - \left( -u \mp \frac{1}{2} + m - E' \right)^{-1}_{fe}, \]
\[ \tilde{E}_{ab}(w) = (w + l + E')^{-1}_{ba} = - \left( -u \mp \frac{1}{2} + m - E' \right)^{-1}_{ba}. \]

We also used the definitions (3.11). Hence the sum of the expressions (3.28) over the indices } c, d \text{ and } g, h \text{ plus the sum of the expressions (3.30) over the index } k \text{ can be rewritten as the sum over the indices } g, h \text{ of the series in } u^{-1},
symmetric group $S_f$ with coefficients in the algebra $U(m)$ of $X(g)$.

Let us consider the braid group corresponding to $\sigma$ respectively. For any reduced decomposition $\sigma$ the elements $\tilde{\sigma}$ satisfy the above displayed relations, instead of the involutions $H_{a,b}$.

The group $H$ is the generator of the subgroup of index two. Denote this subgroup by $H_{a,b}$. Note that $H_{a,b}$ and the Abelian group $Z$ are independent of the choice of a reduced decomposition of $\sigma$.

4. Zhelobenko operators

Let us consider the hyperoctahedral group $H_m$. This is the semidirect product of the symmetric group $S_m$ and the Abelian group $Z_2$, where $S_m$ acts by permutations of the $m$ copies of $Z_2$. In this section, we assume that $m > 0$. The group $H_m$ is generated by the elements $\sigma_a$ with $a = 1, \ldots, m$. The elements $\sigma_a$ with the indices $a = 1, \ldots, m-1$ are elementary transpositions generating the symmetric group $S_m$, so that $\sigma_a = (a, a+1)$. Then $\sigma_m$ is the generator of the $m$-th factor $Z_2$ of $Z_2^n$. The elements $\sigma_1, \ldots, \sigma_m \in H_m$ are involutions and satisfy the braid relations

$$
\sigma_a \sigma_{a+1} \sigma_a = \sigma_{a+1} \sigma_a \sigma_{a+1} \quad \text{for} \quad a = 1, \ldots, m-2;
$$
$$
\sigma_a \sigma_b = \sigma_b \sigma_a \quad \text{for} \quad a = 1, \ldots, b-2;
$$
$$
\sigma_{m-1} \sigma_m \sigma_{m-1} \sigma_m = \sigma_m \sigma_{m-1} \sigma_m \sigma_{m-1}.
$$

Note that $H_m$ is the Weyl group of the simple Lie algebra $\mathfrak{sp}_{2m}$. Let $B_m$ be the braid group corresponding to $\mathfrak{sp}_{2m}$. It is generated by the elements $\tilde{\sigma}_1, \ldots, \tilde{\sigma}_m$ which by definition satisfy the above displayed relations, instead of the involutions $\sigma_1, \ldots, \sigma_m$ respectively. For any reduced decomposition $\sigma = \sigma_{a_1} \cdots \sigma_{a_k}$ in $H_m$ put

$$
\tilde{\sigma} = \tilde{\sigma}_{a_1} \cdots \tilde{\sigma}_{a_k}.
$$

The definition of $\tilde{\sigma}$ is independent of the choice of a reduced decomposition of $\sigma$.

The group $H_m$ also contains the Weyl group of the reductive Lie algebra $\mathfrak{so}_{2m}$ as a subgroup of index two. Denote this subgroup by $H'_m$, it is generated by the elementary transpositions $\sigma_1, \ldots, \sigma_{m-1}$ and by the involution $\sigma'_m = \sigma_m \sigma_{m-1} \sigma_m$. Along with the braid relations between $\sigma_1, \ldots, \sigma_{m-1}$, we also have the braid relations involving $\sigma'_m$,

$$
\sigma_a \sigma'_m = \sigma'_m \sigma_a \quad \text{for} \quad a = 1, \ldots, m-3, m-1;
$$
$$
\sigma_{m-2} \sigma'_m \sigma_{m-2} = \sigma'_m \sigma_{m-2} \sigma'_m.
$$

By comparing this sum with the product of the series $u^\pm(x_i)$ to this sum we describe the action of the extended twisted Yangian $X(g)$ on the subspace (3.14) modulo $q \cdot M$. By comparing this sum with the product of the series (3.4) and (3.5) where $z = m + \frac{1}{2}$, we now prove that the map $\chi$ intertwines the actions of $X(g)$; here we use (1.26) and (2.8). This completes the proof of Theorem 3.1.  

$\square$
When \( m > 1 \), the braid group of \( \mathfrak{so}_{2m} \) is generated by \( m \) elements satisfying the same braid relations instead of the \( m \) involutions \( \sigma_1, \ldots, \sigma_{m-1}, \sigma_m \) respectively. When \( m = 1 \), the braid group corresponding to \( f_m = \mathfrak{so}_2 \) consists of the identity element only.

Now let the indices \( c, d \) run through \(-m, \ldots, -1, 1, \ldots, m\). For \( c > 0 \) we denote \( \bar{c} = m + 1 - c \); for \( c < 0 \) denote \( \bar{c} = -m - 1 - c \). Consider a representation \( \sigma \mapsto \tilde{\sigma} \) of the group \( H_m \) by permutations of \(-m, \ldots, -1, 1, \ldots, m\) such that

\[
\tilde{\sigma}(c) = \overline{\sigma(\bar{c})} \quad \text{for} \quad \sigma \in \mathfrak{S}_m
\]

and \( \tilde{\sigma}_m(c) = -c \) if \(|c| = 1\), while \( \tilde{\sigma}_m(c) = c \) if \(|c| > 1\). We can define an action of the braid group \( \mathfrak{B}_m \) by automorphisms of the Lie algebra \( f_m \), by the assignments

\[
\tilde{\sigma} : F_{cd} \mapsto F_{\tilde{\sigma}(c) \sigma(d)} \quad \text{for} \quad \sigma \in \mathfrak{S}_m ,
\]

\[
\tilde{\sigma}_m : F_{cd} \mapsto (\pm 1)^{\delta_{c1} + \delta_{d1}} F_{\tilde{\sigma}_m(c) \sigma_m(d)} ;
\]

cf. [T]. According to our convention on double signs, the upper sign in \( \pm \) corresponds to \( f_m = \mathfrak{so}_{2m} \), while the lower sign corresponds to \( f_m = \mathfrak{sp}_{2m} \). The automorphism property can be checked by using the relations (2.3), see the proof of Part (i) of Lemma 4.1 below.

This action of the group \( \mathfrak{BD}(C^m \otimes C^n) \) extends to an action of \( \mathfrak{BD}(C^m \otimes C^n) \) by automorphisms of the associative algebra \( U(f_m) \). Note that in the case \( f_m = \mathfrak{so}_{2m} \) the action of \( \mathfrak{BD}(C^m \otimes C^n) \) on \( U(f_m) \) factors to an action of the group \( \mathfrak{H}_m \).

Further, one can define an action of the braid group \( \mathfrak{BD}(C^m \otimes C^n) \) in the following way. Put

\[
\tilde{\sigma}(x_{ai}) = x_{\tilde{\sigma}(a)i} \quad \text{and} \quad \tilde{\sigma}(\partial_{ai}) = \partial_{\tilde{\sigma}(a)i} \quad \text{for} \quad \sigma \in \mathfrak{S}_m ,
\]

\[
\tilde{\sigma}_m(x_{ai}) = x_{ai} \quad \text{and} \quad \tilde{\sigma}_m(\partial_{ai}) = \partial_{ai} \quad \text{for} \quad a > 1 ,
\]

\[
\tilde{\sigma}_m(x_{i1}) = \theta_{1i} \partial_{i1} \quad \text{and} \quad \tilde{\sigma}_m(\partial_{i1}) = \theta_{1i} x_{i1}
\]

where \( i = 1, \ldots, n \). Note that in the case \( f_m = \mathfrak{so}_{2m} \) the element \( \tilde{\sigma}_m^2 \in \mathfrak{B}_m \) acts on \( x_{i1} \) and on \( \partial_{i1} \) as the identity, so that the action of \( \mathfrak{BD}(C^m \otimes C^n) \) on \( \mathfrak{BD}(C^m \otimes C^n) \) factors to an action of the group \( \mathfrak{H}_m \). But in the case \( f_m = \mathfrak{sp}_{2m} \) the element \( \tilde{\sigma}_m^2 \) acts on \( x_{i1} \) and on \( \partial_{i1} \) as minus the identity, because \( \theta_{1i} \theta_{1i} = -1 \) in this case. This is why we use the braid group, rather than the Weyl group \( \mathfrak{H}_m \) of the simple Lie algebra \( \mathfrak{sp}_{2m} \). Taking the tensor product of the actions of \( \mathfrak{BD}(C^m \otimes C^n) \) on the algebras \( U(f_m) \) and \( \mathfrak{BD}(C^m \otimes C^n) \), we get an action of \( \mathfrak{BD}(C^m \otimes C^n) \) by automorphisms of the algebra \( \mathfrak{BD}(C^m \otimes C^n) \).

**Lemma 4.1.** (i) The map \( \zeta_m : U(f_m) \to \mathfrak{BD}(C^m \otimes C^n) \) is \( \mathfrak{BD}(C^m \otimes C^n) \)-equivariant.

(ii) The action of \( \mathfrak{BD}(C^m \otimes C^n) \) on \( \mathfrak{BD}(C^m \otimes C^n) \) leaves invariant any element of the image of \( X(\mathfrak{g}_n) \) under the homomorphism \( \beta_m \).

**Proof.** Let us employ the elements \( p_{ci} \) and \( q_{ci} \) of the algebra \( \mathfrak{BD}(C^m \otimes C^n) \), introduced immediately after stating Proposition 2.3. In terms of these elements, the action of \( \mathfrak{BD}(C^m \otimes C^n) \) on the algebra \( \mathfrak{BD}(C^m \otimes C^n) \) can be described by setting

\[
\tilde{\sigma}(p_{ci}) = p_{\tilde{\sigma}(c)i} \quad \text{and} \quad \tilde{\sigma}(q_{ci}) = q_{\tilde{\sigma}(c)i} \quad \text{for} \quad \sigma \in \mathfrak{S}_m ,
\]

\[
\tilde{\sigma}_m(p_{ci}) = (\pm 1)^{\delta_{c1}} p_{\tilde{\sigma}_m(c)i} \quad \text{and} \quad \tilde{\sigma}_m(q_{ci}) = (\pm 1)^{\delta_{c1}} q_{\tilde{\sigma}_m(c)i}
\]

where \( c = -m, \ldots, -1, 1, \ldots, m \). Part (i) follows by comparing our definition of the action of \( \mathfrak{BD}(C^m \otimes C^n) \) with the description (2.10) of the homomorphism \( \zeta_m \). Part (ii) follows similarly, using the description (2.9) of \( \beta_m \).
Consider the Cartan subalgebra \( \mathfrak{h} \) from the triangular decomposition (2.17). In the notation of this section, our chosen basis of \( \mathfrak{h} \) is \( (F_{-a,-\bar{a}} \mid a = 1, \ldots, m) \). Now let \( (\varepsilon_a \mid a = 1, \ldots, m) \subset \mathfrak{h}^* \) be the dual basis, so that \( \varepsilon_b(F_{-a,-\bar{a}}) = \delta_{ab} \). For \( c < 0 \) put \( \varepsilon_c = -\varepsilon_{-c} \). Thus the element \( \varepsilon_c \in \mathfrak{h}^* \) is defined for every index \( c = -m, \ldots, -1, 1, \ldots, m \).

Consider the root system of the Lie algebra \( f_m \) in \( \mathfrak{h}^* \). Put

\[
\eta_a = \varepsilon_a - \varepsilon_{a+1} \quad \text{for} \quad a = 1, \ldots, m-1.
\]

Also put \( \eta_m = \varepsilon_{m-1} + \varepsilon_m \) in the case \( f_m = \mathfrak{so}_{2m} \), and \( \eta_m = 2\varepsilon_m \) in the case \( f_m = \mathfrak{sp}_{2m} \). Then \( \eta_1, \ldots, \eta_m \) are the simple roots of \( f_m \). Denote by \( \Delta^+ \) the set of positive roots of \( f_m \).

These are the weights \( \varepsilon_a - \varepsilon_b \) and \( \varepsilon_a + \varepsilon_b \) where \( 1 \leq a < b \leq m \) in the case \( f_m = \mathfrak{so}_{2m} \), and the same weights together with \( 2\varepsilon_a \) where \( 1 \leq a \leq m \) in the case \( f_m = \mathfrak{sp}_{2m} \). We assume that in the case \( f_m = \mathfrak{so}_2 \) the root system of \( f_m \) is empty. Let \( \rho \) be halfsum of positive roots of \( f_m \), so that its sequence of labels \( (\rho_1, \ldots, \rho_m) \) is \( (m-1, \ldots, 0) \) in the case \( f_m = \mathfrak{so}_{2m} \), and is \( (m, \ldots, 1) \) in the case \( f_m = \mathfrak{sp}_{2m} \). For each \( a = 1, \ldots, m-1 \) put

\[
E_a = F_{-a,-a+1}, \quad F_a = F_{-a+1,-\bar{a}}, \quad H_a = F_{-a,-\bar{a}} - F_{-a+1,-a+1}. \tag{4.6}
\]

Put

\[
E_m = F_{-m,-m+1}, \quad F_m = F_{m,-m-1}, \quad H_m = F_{-m,-m-1} + F_{m,-m}. \tag{4.7}
\]

in the case \( f_m = \mathfrak{so}_{2m} \) with \( m > 1 \). In the case when \( f_m = \mathfrak{sp}_{2m} \), put

\[
E_m = F_{-m,-m}/2, \quad F_m = F_{m,-m}/2, \quad H_m = F_{-m,-m}. \tag{4.8}
\]

For every possible index \( a \) the three elements \( E_a, F_a, H_a \) of the Lie algebra \( f_m \) span a subalgebra isomorphic to \( \mathfrak{sl}_2 \). They satisfy the commutation relations

\[
[E_a, F_a] = H_a, \quad [H_a, E_a] = 2E_a, \quad [H_a, F_a] = -2F_a. \tag{4.9}
\]

So far we denoted by \( B_m \) the associative algebra \( U(f_m) \otimes \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \). Let us now use a different presentation of the same algebra. Namely, from now until the end of the next section, on we will regard \( B_m \) as the associative algebra generated by the algebras \( U(f_m) \) and \( \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \) with the cross relations

\[
[X, Y] = [\zeta_n(X), Y] \tag{4.10}
\]

for any \( X \in f_m \) and \( Y \in \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \). The brackets at the left hand side of the relation (4.10) denote the commutator in \( B_m \), while the brackets at the right hand side denote the commutator in the algebra \( \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \) embedded to \( B_m \). In particular, we will regard \( U(f_m) \) as a subalgebra of \( B_m \). An isomorphism of this \( B_m \) with the tensor product \( U(f_m) \otimes \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \) can be defined by mapping the elements \( X \in f_m \) and \( Y \in \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \) of \( B_m \) respectively to the elements

\[
X \otimes 1 + 1 \otimes \zeta_n(X) \quad \text{and} \quad 1 \otimes Y
\]

of \( U(f_m) \otimes \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \). Here we use (2.6). The action of the braid group \( \mathcal{B}_m \) on \( B_m \) is defined via its isomorphism of \( B_m \) with \( U(f_m) \otimes \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \). Since the map \( \zeta_n \)
is $\mathfrak{B}_m$-equivariant, the same action of $\mathfrak{B}_m$ is obtained by extending the actions of $\mathfrak{B}_m$ from the subalgebras $U(f_m)$ and $GD(\mathbb{C}^m \otimes \mathbb{C}^n)$ to $B_m$.

Now consider the following two sets of elements of the algebra $U(\mathfrak{h}) \subset U(f_m)$:

\[
\{ F_{aa} - F_{bb} + z, \ F_{aa} + F_{bb} + z \mid 1 \leq a < b \leq m, \ z \in \mathbb{Z} \}, \quad (4.11)
\]
\[
\{ F_{aa} + z \mid 1 \leq a \leq m, \ z \in \mathbb{Z} \}. \quad (4.12)
\]

In the case $f_m = \mathfrak{so}_{2m}$, denote by $\overline{U(\mathfrak{h})}$ the ring of fractions of the commutative algebra $U(\mathfrak{h})$ relative to the set of denominators (4.11). In the case $f_m = \mathfrak{sp}_{2m}$, denote by $\overline{U(\mathfrak{h})}$ the ring of fractions of $U(\mathfrak{h})$ relative to the union of sets (4.11) and (4.12). The elements of the ring $\overline{U(\mathfrak{h})}$ can also be regarded as rational functions on the vector space $\mathfrak{h}^\ast$. The elements of the subalgebra $U(\mathfrak{h}) \subset \overline{U(\mathfrak{h})}$ are then regarded as polynomial functions on $\mathfrak{h}^\ast$.

Denote by $\overline{B}_m$ the ring of fractions of $B_m$ relative to the same set of denominators as was used to define the ring of fractions $\overline{U(\mathfrak{h})}$. But now we regard these denominators as elements of $B_m$ using the embedding of $\mathfrak{h} \subset f_m$ into $B_m$. The ring $\overline{B}_m$ is defined due to the following relations in $B_m$. For $c < 0$ put $\varepsilon_c = -\varepsilon_{-c}$. Thus the element $\varepsilon_c \in \mathfrak{h}^\ast$ is defined for every $c = -m, \ldots, -1, 1, \ldots, m$. Then for any element $H \in \mathfrak{h}$ we have

\[
[H, F_{cd}] = (\varepsilon_d - \varepsilon_c)(H) F_{cd} \quad \text{for} \quad c, d = -m, \ldots, -1, 1, \ldots, m;
\]
\[
[H, x_{ci}] = -\varepsilon_c(H) x_{ci} \quad \text{and} \quad [H, \partial_{ci}] = \varepsilon_c(H) \partial_{ci} \quad \text{for} \quad c = 1, \ldots, m.
\]

So the ring $B_m$ obeys the Ore condition relative to our set of denominators. Using left multiplication by elements of $\overline{U(\mathfrak{h})}$, the ring $\overline{B}_m$ becomes a module of $\overline{U(\mathfrak{h})}$.

The ring $\overline{B}_m$ is also an associative algebra over $\mathbb{C}$. The action of the braid group $\mathfrak{B}_m$ on $B_m$ preserves the set of denominators, so that $\mathfrak{B}_m$ also acts by automorphisms of the algebra $\overline{B}_m$. Using the elements (4.6) and (4.7) when $f_m = \mathfrak{so}_{2m}$, or the elements (4.6) and (4.8) when $f_m = \mathfrak{sp}_{2m}$, for every simple root $\eta_a$ of $f_m$ define a linear map

\[
\xi_a : B_m \rightarrow \overline{B}_m
\]

by setting

\[
\xi_a(Y) = Y + \sum_{s=1}^{\infty} (s! H_a^{(s)})^{-1} E_a^s \hat{F}_a^s(Y) \quad (4.13)
\]

where

\[
H_a^{(s)} = (H_a)(H_a - 1) \cdots (H_a - s + 1)
\]

and $\hat{F}_a$ is the operator of adjoint action corresponding to the element $F_a \in B_m$,

\[
\hat{F}_a(Y) = [F_a, Y].
\]

For a given element $Y \in B_m$ only finitely many terms of the sum (4.13) differ from zero. In the case $f_m = \mathfrak{so}_2$ there are no roots of $f_m$, and no corresponding operators $B_m \rightarrow \overline{B}_m$. On the other hand, in the case when $f_m = \mathfrak{so}_{2m}$ with $m > 1$, by (4.4)

\[
\xi_m \sigma_m = \sigma_m \xi_{m-1},
\]

because
$\tilde{\sigma}_m : E_{m-1} \mapsto F_m , \ F_{m-1} \mapsto F_m , \ H_{m-1} \mapsto H_m .

Let $J$ and $\bar{J}$ be the right ideals of algebras $B_m$ and $\bar{B}_m$ respectively, generated by all elements of the subalgebra $n \subset \mathfrak{f}_m$. The following two properties of the linear operator $\xi_a$ go back to [Z, Section 2]. For any elements $X \in \mathfrak{h}$ and $Y \in B_m$,

\[
\begin{align*}
\xi_a(XY) & \in (X + \eta_a(X)) \xi_a(Y) + \bar{J}, \\
\xi_a(YX) & \in \xi_a(Y) (X + \eta_a(X)) + \bar{J}.
\end{align*}
\] (4.14)

See [KN1, Section 3] for detailed proofs of these two properties. The proofs use only the commutation relations (4.9), not the actual form of elements $E_a, F_a, H_a$.

The property (4.14) allows us to define a linear map $\bar{\xi}_a : \mathbb{B}_m \to \mathbb{J} \setminus \bar{\mathbb{B}}_m$ by

\[
\bar{\xi}_a(XY) = Z \xi_a(Y) + \bar{J} \quad \text{for} \quad X \in \mathbb{U}(\mathfrak{h}) \quad \text{and} \quad Y \in B_m,
\]

where the element $Z \in \mathbb{U}(\mathfrak{h})$ is defined by the equality

\[
Z(\mu) = X(\mu + \eta_a) \quad \text{for} \quad \mu \in \mathfrak{h}^*.
\]

when both $X$ and $Z$ are regarded as rational functions on $\mathfrak{h}^*$. The backslash in $\mathbb{J} \setminus \bar{\mathbb{B}}_m$ indicates that the quotient is taken relative to a right ideal of $\bar{\mathbb{B}}_m$. For the proofs of the next two propositions see [KN3, Section 4].

**Proposition 4.2.** For any simple root $\eta_a$ of $\mathfrak{f}_m$ we have the inclusion $\tilde{\sigma}(\mathbb{J}) \subset \ker \bar{\xi}_a$ where $\sigma = \sigma_a$ unless $\mathfrak{f}_m = \mathfrak{so}_2m$ and $a = m$, in which case $\sigma = \sigma'_m$.

Recall that $n'$ denotes the nilpotent subalgebra of $\mathfrak{f}_m$ spanned by all the elements $F_{cd}$ with $c < d$. Due to the relation $F_{cd} = -\varepsilon_{cd} F_{-d,-c}$ the subalgebra $n'$ is also spanned by the elements $F_{cd}$ with $c < d$ and $c < 0$. Now for any $a = 1, \ldots, m$ denote by $n'_a$ the vector subspace of $\mathfrak{f}_m$ spanned by all the elements $F_{cd}$ with $c < d$ and $c < 0$, except the element $E_a$. Denote by $J'$ the left ideal of $B_m$, generated by the elements $X - \zeta_n(X)$ where $X \in n'$. Under the isomorphism of $B_m$ with $\mathbb{U}(\mathfrak{f}_m) \otimes \mathcal{G}\mathcal{D}(\mathbb{C}^m \otimes \mathbb{C}^n)$, for any $X \in \mathfrak{f}_m$ the difference $X - \zeta_n(X) \in B_m$ is mapped to the element

\[
X \otimes 1 \in \mathbb{U}(\mathfrak{f}_m) \otimes 1 \subset \mathbb{U}(\mathfrak{f}_m) \otimes \mathcal{G}\mathcal{D}(\mathbb{C}^m \otimes \mathbb{C}^n).
\] (4.15)

Let $J'_a$ be the left ideal of $B_m$, generated by the elements $X - \zeta_n(X)$ with $X \in n'_a$, and by the element $E_a \in B_m$. Denote $J' = \mathbb{U}(\mathfrak{h})J'$ and $J'_a = \mathbb{U}(\mathfrak{h})J'_a$. Then both $J'$ and $J'_a$ are left ideals of the algebra $\bar{\mathbb{B}}_m$.

**Proposition 4.3.** For any simple root $\eta_a$ of $\mathfrak{f}_m$ we have $\bar{\xi}_a(\tilde{\sigma}(J'_a)) \subset J' + \bar{J}$ where $\sigma = \sigma_a$ unless $\mathfrak{f}_m = \mathfrak{so}_2m$ and $a = m$, in which case $\sigma = \sigma'_m$.

Proposition 4.2 allows us to define for any simple root $\eta_a$ a linear map

\[
\bar{\xi}_a : \mathbb{J} \setminus \bar{\mathbb{B}}_m \to \mathbb{J} \setminus \bar{\mathbb{B}}_m
\]

as the composition $\bar{\xi}_a \tilde{\sigma}$ applied to the elements of $\bar{\mathbb{B}}_m$ taken modulo $\bar{J}$. Here the simple reflection $\sigma \in \mathfrak{h}_m$ is chosen as in Proposition 4.2. In their present form, the operators $\bar{\xi}_1, \ldots, \bar{\xi}_m$ on the vector space $\mathbb{J} \setminus \bar{\mathbb{B}}_m$ have been defined in [KO]. We call them the Zhelobenko operators. For the proof of the next proposition see [KO, Sections 4 and 6].
Proposition 4.4. The Zhelobenko operators satisfy the braid relations corresponding to the Lie algebra \( \mathfrak{f}_m \). Namely, in the case \( \mathfrak{f}_m = \mathfrak{sp}_{2m} \) we have
\[
\begin{align*}
\xi_a \xi_{a+1} \xi_a &= \xi_a \xi_{a+1} \xi_a \quad &\text{for} \quad a = 1, \ldots, m-2; \\
\xi_a \xi_b &= \xi_b \xi_a \quad &\text{for} \quad a = 1, \ldots, b-2; \\
\xi_{m-1} \xi_m \xi_{m-1} \xi_m &= \xi_m \xi_{m-1} \xi_m \xi_{m-1}.
\end{align*}
\]

In the case when \( \mathfrak{f}_m = \mathfrak{so}_{2m} \) and \( m > 1 \), we have the same relations (4.16) and (4.17) between \( \xi_1, \ldots, \xi_{m-1} \) as in the case \( \mathfrak{f}_m = \mathfrak{sp}_{2m} \) above, and also the relations
\[
\begin{align*}
\xi_a \xi_m &= \xi_m \xi_a \quad &\text{for} \quad a = 1, \ldots, m-3, m-1; \\
\xi_{m-2} \xi_m \xi_{m-2} &= \xi_m \xi_{m-2} \xi_m.
\end{align*}
\]

For \( \mathfrak{f}_m = \mathfrak{sp}_{2m} \), by using any reduced decomposition of an element \( \sigma \in \mathcal{H}_m \) in terms of the involutions \( \sigma_1, \ldots, \sigma_m \), we can define a linear operator
\[
\tilde{\xi}_\sigma : \mathcal{J} \setminus \mathbb{B}_m \to \mathcal{J} \setminus \mathbb{B}_m
\] (4.19)
in the usual way, like in (4.1). This definition of \( \tilde{\xi}_\sigma \) is independent of the choice of a reduced decomposition of \( \sigma \) due to Proposition 4.4.

When \( \mathfrak{f}_m = \mathfrak{sp}_{2m} \), the number of the factors \( \sigma_1, \ldots, \sigma_m \) in any reduced decomposition \( \sigma \in \mathcal{H}_m \) will be denoted \( \ell(\sigma) \). This number is also independent of the choice of the decomposition, and is equal to the number of elements in the set
\[
\Delta_\sigma = \{ \eta \in \Delta^+ \mid \sigma(\eta) \notin \Delta^+ \}
\] (4.20)
where \( \Delta^+ \) denotes the set of positive roots of the Lie algebra \( \mathfrak{sp}_{2m} \).

Now suppose that \( \mathfrak{f}_m = \mathfrak{so}_{2m} \). Then by using any reduced decomposition in terms of \( \sigma_1, \ldots, \sigma_{m-1}, \sigma'_m \), we can define a linear operator (4.19) for every element \( \sigma \in \mathcal{H}'_m \).

Again, this definition is independent of the choice of a reduced decomposition of \( \sigma \) due to Proposition 4.4. It turns out that in this case we can extend the definition of the operator (4.19) to any element \( \sigma \in \mathcal{H}_m \), where \( m > 1 \). Note that in this case the action of the element \( \tilde{\sigma}_m \) on \( \mathbb{B}_m \) preserves the ideal \( \mathcal{J} \), and therefore induces a linear operator on the quotient vector space \( \mathcal{J} \setminus \mathbb{B}_m \). This operator will be again denoted by \( \tilde{\sigma}_m \). The extension of the definition of the operators (4.19) to \( \sigma \in \mathcal{H}_m \) is based on the next lemma, which has been proved in [KN3, Section 4].

Lemma 4.5. When \( \mathfrak{f}_m = \mathfrak{so}_{2m} \) and \( m > 1 \), the operators \( \tilde{\xi}_1, \ldots, \tilde{\xi}_{m-1}, \tilde{\sigma}_m \) on \( \mathcal{J} \setminus \mathbb{B}_m \) satisfy the same relations, as the \( m \) generators of the braid group \( \mathcal{B}_m \) respectively. Then we also have the relation
\[
\tilde{\xi}_m = \tilde{\sigma}_m \tilde{\xi}_{m-1} \tilde{\sigma}_m.
\] (4.21)

Now for \( \mathfrak{f}_m = \mathfrak{so}_{2m} \) with any \( m > 1 \), take any decomposition of an element \( \sigma \in \mathcal{H}_m \) in terms of the involutions \( \sigma_1, \ldots, \sigma_m \) such that the number of occurencies of \( \sigma_1, \ldots, \sigma_{m-1} \) in the decomposition is minimal possible. For \( \mathfrak{f}_m = \mathfrak{so}_{2m} \) the symbol \( \ell(\sigma) \) will denote this minimal number. Note that unlike for \( \mathfrak{f}_m = \mathfrak{sp}_{2m} \), here we do not count the occurencies of \( \sigma_m \) in the decomposition. All the decompositions of \( \sigma \in \mathcal{H}_m \) with the minimal number of
occurrences of $\sigma_1, \ldots, \sigma_{m-1}$ can be obtained from each other by using the braid relations between $\sigma_1, \ldots, \sigma_m \in \mathfrak{S}_m$ along with the relation $\sigma_m^2 = 1$.

By substituting the operators $\xi_1, \ldots, \xi_{m-1}, \xi_m$ on $\mathfrak{J} \setminus \mathfrak{B}_m$ for involutions $\sigma_1, \ldots, \sigma_m$ in such a decomposition of $\sigma \in \mathfrak{S}_m$, we obtain another operator on $\mathfrak{J} \setminus \mathfrak{B}_m$. The latter operator does not depend on the choice of a decomposition because of the first statement of Lemma 4.5, and because the operator $\tilde{\sigma}_m^2$ on the vector space $\mathfrak{J} \setminus \mathfrak{B}_m$ is the identity in the case $\tilde{f}_m = \mathfrak{so}_{2m}$ considered here. Moreover for $\sigma \in \mathfrak{S}_m' \subset \mathfrak{S}_m$, the operator on $\mathfrak{J} \setminus \mathfrak{B}_m$ obtained by the latter substitution coincides with the operator (4.19). Indeed, for $\tilde{f}_m = \mathfrak{so}_{2m}$ the operator (4.19) has been defined by substituting the Zhelobenko operators $\xi_1, \ldots, \xi_{m-1}, \xi_m$ for $\sigma_1, \ldots, \sigma_{m-1}, \sigma_m$ in any reduced decomposition of $\sigma \in \mathfrak{S}_m'$. The coincidence of the two operators for $\sigma \in \mathfrak{S}_m'$ now follows from the relation (4.21). Thus we have extended the definition of the operator (4.19) from $\sigma \in \mathfrak{S}_m'$ to all $\sigma \in \mathfrak{S}_m$.

Note that for $\tilde{f}_m = \mathfrak{so}_{2m}$ and $\sigma \in \mathfrak{S}_m'$, the number $\ell(\sigma)$ is equal to the length of a reduced decomposition of $\sigma$ in terms of $\sigma_1, \ldots, \sigma_{m-1}, \sigma_m$. Thus we have also extended the standard length function from the Weyl group $\mathfrak{S}_m'$ of $\mathfrak{so}_{2m}$ to the hyperoctahedral group $\mathfrak{S}_m$. Moreover for any $\sigma \in \mathfrak{S}_m$, not only for $\sigma \in \mathfrak{S}_m'$, the number $\ell(\sigma)$ equals the number of elements in the set (4.20), where $\Delta^+$ is the set of positive roots of $\mathfrak{so}_{2m}$.

From now onwards we shall consider $\tilde{f}_m = \mathfrak{so}_{2m}$ and $\tilde{f}_m = \mathfrak{sp}_{2m}$ simultaneously, and will work with the operators (4.19) for all elements $\sigma \in \mathfrak{S}_m$. In particular, in the case $\tilde{f}_m = \mathfrak{so}_{2m}$ we will assume that the operator (4.19) with $\sigma = \sigma_m$ acts as $\tilde{\sigma}_m$.

The restriction of the action (4.3), (4.4) of the braid group $\mathfrak{B}_m$ on $\tilde{f}_m$ to the Cartan subalgebra $\mathfrak{h}$ factors to an action of the hyperoctahedral group $\mathfrak{S}_m$. This is the standard action of the Weyl group of $\tilde{f}_m = \mathfrak{sp}_{2m}$. The resulting action of the subgroup $\mathfrak{S}_m' \subset \mathfrak{S}_m$ on $\mathfrak{h}$ is the standard action of the Weyl group of $\tilde{f}_m = \mathfrak{so}_{2m}$. The group $\mathfrak{S}_m'$ also acts on the dual vector space $\mathfrak{h}^*$, so that $\sigma(\varepsilon_c) = \varepsilon_{\sigma(c)}$ for any $\sigma \in \mathfrak{S}_m$ and any $c = -m, \ldots, -1, 1, \ldots, m$. Unlike in (4.2), here we use the natural action of the group $\mathfrak{S}_m$ by permutations of $-m, \ldots, -1, 1, \ldots, m$. Thus $\sigma_a \in \mathfrak{S}_m$ with $1 \leq a < m$ exchanges $a, a + 1$ and also exchanges $-a, -a - 1$ while $\sigma_m \in \mathfrak{S}_m$ exchanges $m, -m$. Note that we always have $\sigma(-c) = -\sigma(c)$. If we identify each weight $\mu \in \mathfrak{h}^*$ with the sequence $(\mu_1, \ldots, \mu_m)$ of its labels, then

$$\sigma : (\mu_1, \ldots, \mu_m) \mapsto (\mu_{\sigma^{-1}(m)} , \ldots , \mu_{\sigma^{-1}(1)} ) \quad \text{for} \quad \sigma \in \mathfrak{S}_m,$$

$$\sigma_m : (\mu_1, \ldots, \mu_m) \mapsto (\mu_1, \mu_m, \ldots, \mu_{m-1}, -\mu_m).$$

The shifted action of the group $\mathfrak{S}_m$ on the set $\mathfrak{h}^*$ is defined by the assignment

$$\mu \mapsto \sigma \circ \mu = \sigma(\mu + \rho) - \rho \quad \text{for} \quad \sigma \in \mathfrak{S}_m.$$

By regarding the elements of the commutative algebra $\overline{\mathfrak{U}(\mathfrak{h})}$ as rational functions on the vector space $\mathfrak{h}^*$ we can also define an action of the group $\mathfrak{S}_m$ on this algebra:

$$(\sigma \circ X)(\mu) = X(\sigma^{-1} \circ \mu) \quad \text{for} \quad X \in \overline{\mathfrak{U}(\mathfrak{h})}. \quad (4.22)$$

The next proposition has been also proved in [KN3, Section 4].

**Proposition 4.6.** For any $\sigma \in \mathfrak{S}_m$, $X \in \overline{\mathfrak{U}(\mathfrak{h})}$ and $Y \in \mathfrak{J} \setminus \mathfrak{B}_m$ we have the relations

$$\tilde{\xi}_\sigma(\sigma X Y) = (\sigma \circ X) \tilde{\xi}_\sigma(Y), \quad (4.23)$$

$$\tilde{\xi}_\sigma(Y X) = \tilde{\xi}_\sigma(Y)(\sigma \circ X).$$
5. Intertwining operators

Let \( \delta = (\delta_1, \ldots, \delta_m) \) be any sequence of \( m \) elements from \( \{1, -1\} \). The hyperoctahedral group \( \mathcal{H}_m \) acts on the set of all these sequences naturally, so that the generator \( \sigma_a \in \mathcal{H}_m \) with \( a < m \) acts on \( \delta \) as the transposition of \( \delta_a \) and \( \delta_{a+1} \), while the generator \( \sigma_m \in \mathcal{H}_m \) changes the sign of \( \delta_m \). Let \( \delta_+ = (1, \ldots, 1) \) be the sequence of \( m \) elements 1. Given any sequence \( \delta \), take the composition of the automorphisms of the ring \( \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \),

\[ x_{\bar{a}i} \mapsto \theta_i \partial_{\bar{a}i} \quad \text{and} \quad \partial_{\bar{a}i} \mapsto \theta_i x_{\bar{a}i} \quad \text{whenever} \quad \delta_a = -1. \]  

(5.1)

Here \( a \geq 1 \) and \( i = 1, \ldots, n \). Let us denote by \( \varpi \) this composition. In particular, the automorphism \( \varpi \) corresponding to \( \delta = (1, \ldots, 1, -1) \) coincides with the action of \( \tilde{\sigma}_m \) on \( \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \), see (4.5). In the case \( f_m = \mathfrak{sp}_{2m} \), the automorphism \( \varpi \) is involutive for any \( \delta \). But in the case \( f_m = \mathfrak{so}_{2m} \), the square \( \varpi^2 \) maps

\[ x_{\bar{a}i} \mapsto -x_{\bar{a}i} \quad \text{and} \quad \partial_{\bar{a}i} \mapsto -\partial_{\bar{a}i} \quad \text{whenever} \quad \delta_a = -1. \]

For any \( f_m \)-module \( V \), the action of \( X(\mathfrak{g}_n) \) on \( \mathcal{F}_m(V) = V \otimes \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \) is defined by the homomorphism \( \beta_m : X(\mathfrak{g}_n) \to \mathcal{U}(f_m) \otimes \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \), see Proposition 2.3. Further, the action of the Lie algebra \( f_m \) on the second tensor factor \( \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \) of \( \mathcal{F}_m(V) \) is defined by means of homomorphism \( \zeta_n : \mathcal{U}(f_m) \to \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \), see definition (2.6). Here any element of the ring \( \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \) acts on the vector space \( \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n) \) naturally. We can modify the latter action, by making any element \( Y \in \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \) act on \( \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n) \) via the natural action of \( \varpi(Y) \). Then we get another \( \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \)-module, with the same underlying vector space \( \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n) \) for every \( \delta \).

For any \( f_m \)-module \( V \), we can now define a bimodule \( \mathcal{F}_\delta(V) \) of \( f_m \) and \( X(\mathfrak{g}_n) \). Its underlying vector space is the same \( V \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n) \) for every \( \delta \). The action of \( X(\mathfrak{g}_n) \) on \( \mathcal{F}_\delta(V) \) is defined by pushing the homomorphism \( \beta_m \) forward through the automorphism \( \varpi \), applied to \( \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \) as to the second tensor factor of the target of \( \beta_m \). The action of \( f_m \) on \( \mathcal{F}_\delta(V) \) is also defined by pushing the homomorphism \( \zeta_n \) forward through the automorphism \( \varpi \). Thus the actions of \( X(\mathfrak{g}_n) \) and \( f_m \) on the bimodule \( \mathcal{F}_\delta(V) \) are respectively determined by the compositions of the homomorphisms

\[ X(\mathfrak{g}_n) \xrightarrow{\beta_m} \mathcal{U}(f_m) \otimes \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \xrightarrow{1 \otimes \varpi} \mathcal{U}(f_m) \otimes \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n), \]

\[ \mathcal{U}(f_m) \xrightarrow{1 \otimes \zeta_n} \mathcal{U}(f_m) \otimes \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \xrightarrow{1 \otimes \varpi} \mathcal{U}(f_m) \otimes \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n). \]

Note that here we have

\[ \mathcal{F}_m(V) = \mathcal{F}_{\delta_+}(V). \]

Now let \( \mu \in \mathfrak{h}^* \) be any weight of \( f_m \), such that

\[ \mu_a - \mu_b \notin \mathbb{Z} \quad \text{and} \quad \mu_a + \mu_b \notin \mathbb{Z} \quad \text{whenever} \quad 1 \leq a < b \leq m. \]  

(5.2)

In the case \( f_m = \mathfrak{sp}_{2m} \) also suppose that, in addition to (5.2),

\[ 2\mu_a \notin \mathbb{Z} \quad \text{whenever} \quad 1 \leq a \leq m. \]  

(5.3)

We shall now proceed to show how for every element \( \sigma \in \mathcal{H}_m \), the Zhelobenko operator (4.19) determines an \( X(\mathfrak{g}_n) \)-intertwining operator
\[ \mathcal{F}_m (M_\mu)_n \rightarrow \mathcal{F}_\delta (M_{\sigma \circ \mu})_n \quad \text{where} \quad \delta = \sigma (\delta_+). \quad (5.4) \]

In this section we keep regarding \( B_m \) as the associative algebra generated by \( U(f_m) \) and \( \mathcal{G}D(C^m \otimes C^n) \) with the cross relations \((4.10)\). Let \( I_\delta \) be the left ideal of algebra \( B_m \) generated by the elements \( x_{\bar{a},i} \) with \( \delta_a = -1 \), and the elements \( \partial_{\bar{a},i} \) with \( \delta_a = 1 \). Here \( a = 1, \ldots, m \) and \( i = 1, \ldots, m \). Note that in terms of the elements \( q_{ci} \) introduced immediately after stating Proposition 2.3, the left ideal \( I_\delta \) is generated by the elements \( q_{-\delta_a \bar{a},i} \) where again \( a = 1, \ldots, m \) and \( i = 1, \ldots, m \). In particular, the ideal \( I_{\delta_+} \) is generated by all the left derivations \( \partial_{ai} \). Let \( \hat{I}_\delta \) be the left ideal of \( \bar{B}_m \) generated by the same elements as the ideal of \( I_\delta \) of \( B_m \).

Consider the image of the ideal \( \hat{I}_\delta \) in the quotient space \( J \setminus \bar{B}_m \), that is the subspace \( J \setminus (\hat{I}_\delta + \bar{J}) \) in the quotient space \( J \setminus \bar{B}_m \). The image will be occasionally denoted by the same symbol \( \bar{I}_\delta \). In the context of the next proposition, this should cause no confusion.

**Proposition 5.1.** For any \( \sigma \in \mathfrak{H}_m \) the operator \( \tilde{\xi}_\sigma \) maps the subspace \( I_{\delta_+} \) to \( I_{\sigma (\delta_+)} \).

**Proof.** For any \( a = 1, \ldots, m - 1 \) consider the operator \( \hat{F}_a \) corresponding to the element \( F_a \in B_m \). By \((4.6)\) and \((2.6),(4.10)\) for any \( Y \in \mathcal{G}D(C^m \otimes C^n) \) we have

\[ \hat{F}_a(Y) = - \sum_{k=1}^n [x_{\bar{a},k} \partial_{a+1} Y]. \]

Similarly, in the case \( f_m = \mathfrak{sp}_{2m} \) by \((4.8)\) for any \( Y \in \mathcal{G}D(C^m \otimes C^n) \) we have

\[ \hat{F}_m(Y) = \sum_{k=1}^n [x_{\bar{m},k} x_{m,k} Y] / 2. \]

In the case \( f_m = \mathfrak{so}_{2m} \) we do not need to consider the operator \( \hat{F}_m \), because in this case the operator \((4.19)\) corresponding to \( \sigma = \sigma_m \) acts on \( J \setminus \bar{B}_m \) as \( \bar{\sigma}_m \) by our definition.

The above description of the action of \( \hat{F}_a \) with \( a < m \) on \( \mathcal{G}D(C^m \otimes C^n) \) shows that this action preserves each of the two \( 2n \) dimensional subspaces, spanned by the vectors

\[ x_{\bar{a},i} \quad \text{and} \quad x_{a+1, i} \quad \text{where} \quad i = 1, \ldots, n; \quad (5.5) \]

\[ \partial_{\bar{a},i} \quad \text{and} \quad \partial_{a+1, i} \quad \text{where} \quad i = 1, \ldots, n. \quad (5.6) \]

This action also maps to zero the \( 2n \) dimensional subspace, spanned by

\[ x_{\bar{a},i} \quad \text{and} \quad \partial_{a+1, i} \quad \text{where} \quad i = 1, \ldots, n. \quad (5.7) \]

Therefore for any \( \delta \), the operator \( \tilde{\xi}_a \) with \( a < m \) maps the left ideal \( \bar{I}_\delta \) of \( \bar{B}_m \) to the image of \( \bar{I}_\delta \) in \( J \setminus \bar{B}_m \), unless \( \delta_a = 1 \) and \( \delta_{a+1} = -1 \). The operator \( \tilde{\xi}_a \) on \( J \setminus \bar{B}_m \) was defined by taking the composition of \( \xi_a \) and \( \sigma_\delta \). Hence \( \tilde{\xi}_a \) with \( a < m \) maps the image of \( \bar{I}_\delta \) to the image of \( I_{\sigma(a)(\delta)} \), unless \( \delta_a = -1 \) and \( \delta_{a+1} = 1 \).

In the case \( f_m = \mathfrak{sp}_{2m} \), the action of \( \hat{F}_m \) on the vector space \( \mathcal{G}D(C^m \otimes C^n) \) maps to zero the \( n \) dimensional subspace spanned by the elements

\[ x_{\bar{m},i} = x_{1,i} \quad \text{where} \quad i = 1, \ldots, n. \quad (5.8) \]
Therefore the operator $\xi_{m}$ maps the left ideal $I_{\delta}$ of $B_{m}$ to the image of $I_{\delta}$ in $J \setminus B_{m}$, unless $\delta_{m} = 1$. Hence the operator $\xi_{m}$ on $J \setminus B_{m}$ maps the image of $I_{\delta}$ to the image of $I_{\sigma_{m}(\delta)}$, unless $\delta_{m} = -1$. In the case $f_{m} = so_{2m}$, we just note that $\sigma_{m}$ maps the image of $I_{\delta}$ in $J \setminus B_{m}$ to the image of $I_{\sigma_{m}(\delta)}$.

From now on we will denote the image of the ideal $I_{\delta}$ in the quotient space $J \setminus B_{m}$ by the same symbol. Put

$$\hat{\delta} = \sum_{a=1}^{m} \delta_{a} \varepsilon_{a} \in h^{*}.$$  

Then for every $\sigma \in \mathcal{H}_{m}$ we have the equality $\overline{\sigma(\hat{\delta})} = \sigma(\hat{\delta})$ where at the right hand side we use the action of the group $\mathcal{H}_{m}$ on $h^{*}$. Let $(\cdot, \cdot)$ be the standard bilinear form on $h^{*}$, so that the basis of weights $\varepsilon_{a}$ with $a = 1, \ldots, m$ is orthonormal. The above remarks on the action of the Zhelobenko operators on $I_{\delta}$ can now be restated as follows:

$$\text{if } (\hat{\delta}, \varepsilon_{a} - \varepsilon_{a+1}) \geq 0 \text{ then } \xi_{a}(I_{\delta}) \subset I_{\sigma_{a}(\delta)} \text{ for } a = 1, \ldots, m-1; \quad (5.9)$$

$$\text{if } (\hat{\delta}, \varepsilon_{m}) > 0 \text{ then } \xi_{m}(I_{\delta}) \subset I_{\sigma_{m}(\delta)} \text{ for } f_{m} = sp_{2m}. \quad (5.10)$$

We shall prove Proposition 5.1 by induction on the length of a reduced decomposition of $\sigma \in \mathcal{H}_{m}$ in terms of $\sigma_{1}, \ldots, \sigma_{m}$. This number has been denoted by $\ell(\sigma)$ in the case $f_{m} = sp_{2m}$, but may be different from the number denoted by $\ell(\sigma)$ in the case $f_{m} = so_{2m}$. Recall that in both cases $\ell(\sigma)$ equals the number of elements in the set (4.20), where $\Delta^{+}$ is the set of positive roots of $f_{m}$.

If $\sigma$ is the identity element of $\mathcal{H}_{m}$, Proposition 5.1 is tautological. Suppose that for some $\sigma \in \mathcal{H}_{m}$,

$$\xi_{\sigma}(I_{\delta_{+}}) \subset I_{\sigma(\delta_{+})}.$$  

Take $\sigma_{a} \in \mathcal{H}_{m}$ with $1 \leq a \leq m$, such that $\sigma_{a} \sigma$ has a longer reduced decomposition in terms of $\sigma_{1}, \ldots, \sigma_{m}$ than $\sigma$. If $f_{m} = so_{2m}$ and $a = m$, then $\xi_{\sigma_{m}} = \sigma_{m} \xi_{\sigma}$ and we need the inclusion

$$\tilde{\sigma}_{m}(I_{\sigma(\delta_{+})}) \subset I_{\sigma_{m}\sigma(\delta_{+})}, \quad (5.11)$$

which holds by the definition of the action of $\mathcal{H}_{m}$ on $J \setminus B_{m}$.

We may exclude the case when $f_{m} = so_{2m}$ and $a = m$, and assume that

$$\ell(\sigma_{a} \sigma) = \ell(\sigma) + 1. \quad (5.12)$$

Firstly, suppose that $a < m$ here. Let us then prove the inclusion

$$\xi_{a}(I_{\sigma(\delta_{+})}) \subset I_{\sigma_{a}\sigma(\delta_{+})}.$$  

By (5.9), the latter inclusion will have place if

$$(\overline{\sigma(\delta_{+})}, \varepsilon_{a} - \varepsilon_{a+1}) = (\sigma(\hat{\delta}_{+}), \varepsilon_{a} - \varepsilon_{a+1}) \geq 0.$$  

But the condition (5.12) for $a < m$ implies that $\varepsilon_{a} - \varepsilon_{a+1} \in \sigma(\Delta^{+})$. Indeed, because the root $\varepsilon_{a} - \varepsilon_{a+1}$ of $f_{m}$ is simple, $\sigma_{a}(\eta) \in \Delta^{+}$ for any $\eta \in \Delta^{+}$ such that $\eta \neq \varepsilon_{a} - \varepsilon_{a+1}$. Since $\ell(\sigma)$ and $\ell(\sigma_{a} \sigma)$ are the numbers of elements in $\Delta_{\sigma}$ and $\Delta_{\sigma_{a} \sigma}$ respectively, here $\varepsilon_{a} - \varepsilon_{a+1} \in \sigma(\Delta^{+})$. So $\varepsilon_{a} - \varepsilon_{a+1} = \sigma(\varepsilon_{b} - \varepsilon_{c})$ where $1 \leq b \leq m$ and $1 \leq |c| \leq m$. Thus
Now suppose that \( a = m \). Here we assume that \( f_m = \mathfrak{sp}_{2m} \). We need the inclusion
\[
\xi_m(\mathbf{1}_{\sigma(\delta_+)} \subset \mathbf{1}_{\sigma_m(\delta_+)}).
\]
It will have place if
\[
(\sigma(\delta_+), \varepsilon_m) = (\sigma(\delta_+), \varepsilon_b) > 0.
\]
But the condition (5.12) for \( a = m \) implies that \( 2\varepsilon_m \in \sigma(\Delta^+) \), where \( \Delta^+ \) is the set of positive roots of \( \mathfrak{sp}_{2m} \). Indeed, because the root \( 2\varepsilon_m \) of \( \mathfrak{sp}_{2m} \) is simple, \( \sigma_m(\eta) \in \Delta^+ \) for any \( \eta \in \Delta^+ \) such that \( \eta \neq 2\varepsilon_m \). Since \( \ell(\sigma) \) and \( \ell(\sigma_m) \) are the numbers of elements in \( \Delta_\sigma \) and \( \Delta_{\sigma_m} \) respectively, here \( 2\varepsilon_m \in \sigma(\Delta^+) \). So \( \varepsilon_m = \sigma(\varepsilon_b) \) where \( 1 \leq b \leq m \). Thus
\[
(\sigma(\delta_+), \varepsilon_m) = (\sigma(\delta_+), \sigma(\varepsilon_b)) = (\delta_+, \varepsilon_b) > 0. \tag{5.13}
\]

**Corollary 5.2.** For any \( \sigma \in \mathfrak{h}_m \) the operator \( \xi_\sigma \) on \( J \setminus \mathfrak{b}_m \) maps
\[
J \setminus (J' + I_{\delta_+} + J) \to J \setminus (J' + I_{\sigma(\delta_+)} + J).
\]

**Proof.** We will extend the arguments used in the proof of Proposition 5.1. In particular, we will again use the length of a reduced decomposition of \( \sigma \) in terms of \( \sigma_1, \ldots, \sigma_m \). If \( \sigma \) is the identity element of \( \mathfrak{h}_m \), then the required statement is tautological. Now suppose that for some \( \sigma \in \mathfrak{h}_m \) the statement of Corollary 5.2 is true. Take any simple reflection \( \sigma_a \in \mathfrak{h}_m \) with \( 1 \leq a \leq m \), such that \( \sigma_a \sigma \) has a longer reduced decomposition in terms of \( \sigma_1, \ldots, \sigma_m \) than \( \sigma \). In the case \( f_m = \mathfrak{so}_{2m} \) we may assume that \( a < m \), because in that case the required statement for \( \sigma_m \sigma \) instead of \( \sigma \) is provided by (5.11).

Thus we have the equality (5.12). With the above assumption on \( a \), we have proved that (5.12) implies
\[
(\sigma(\delta_+), \eta_a) \geq 0. \tag{5.13}
\]
Here \( \eta_a \) is the simple root corresponding to \( \sigma_a \). But (5.13) implies the equality
\[
J' + I_{\sigma(\delta_+)} = J_a' + I_{\sigma(\delta_+)} \tag{5.14}
\]
of left ideals of \( \mathfrak{b}_m \). Indeed, the left and right hand sides of (5.14) differ by the elements \( Y\zeta_n(E_a) \) where \( Y \) ranges over \( \mathfrak{b}_m \). The condition (5.13) implies that \( \zeta_n(E_a) \in I_{\sigma(\delta_+)} \), see the definition (2.6) and the arguments in the beginning of proof of Proposition 5.1. Using Proposition 4.3 and the induction step from our proof of Proposition 5.1, \( \xi_a \) maps
\[
J \setminus (J' + I_{\sigma(\delta_+)} + J) = J \setminus (J_a' + I_{\sigma(\delta_+)} + J) \to J \setminus (J' + I_{\sigma_m(\delta_+)} + J).
\]
This makes the induction step of our proof of Corollary 5.2. \( \square \)

Let \( I_{\mu, \delta} \) be the left ideal of the algebra \( \mathfrak{b}_m \) generated by \( I_{\delta} + J' \) and by the elements
\[
F_{-\alpha, -\alpha} - \zeta_n(F_{-\alpha, -\alpha}) - \mu_a \quad \text{where} \quad a = 1, \ldots, m.
\]
Recall that under the isomorphism of the algebra \( \mathfrak{b}_m \) with \( U(f_m) \otimes GD(\mathbb{C}^m \otimes \mathbb{C}^n) \), the difference \( X - \zeta_n(X) \in \mathfrak{b}_m \) for every \( X \in f_m \) is mapped to the element (4.15). Denote by \( I_{\mu, \delta} \) the subspace \( \overline{\mathfrak{b}_m} I_{\mu, \delta} \) of \( \mathfrak{b}_m \), this is also a left ideal of \( \mathfrak{b}_m \).
Theorem 5.3. For any element $\sigma \in H^m$ the operator $\tilde{\xi}_\sigma$ on $J \setminus B_m$ maps

$$J \setminus (I_{\mu,\delta} + J) \to J \setminus (I_{\sigma \circ \mu, \sigma(\delta) + J}).$$

Proof. Let $\kappa$ be a weight of $f_m$ with the sequence of labels $(\kappa_1, \ldots, \kappa_m)$. Suppose that the weight $\kappa$ satisfies the conditions (5.2) instead of $\mu$. In the case $f_m = sp_{2m}$ we also suppose that $\kappa$ satisfies the conditions (5.3) instead of $\mu$. Denote by $\tilde{I}_{\kappa, \delta}$ be the left ideal of $B_m$ generated by $I_{\delta} + J'$ and by the elements

$$F_{-a,-\bar{a}} - \kappa_a \quad \text{where} \quad a = 1, \ldots, m.$$ 

Proposition 4.6 and Corollary 5.2 imply that the operator $\tilde{\xi}_\sigma$ on $J \setminus B_m$ maps

$$J \setminus (\tilde{I}_{\kappa, \delta} + J) \to J \setminus (\tilde{I}_{\sigma \circ \kappa, \sigma(\delta) + J}).$$

Now choose $\kappa_a = \mu_a + n/2$ for $a = 1, \ldots, m$. \hspace{1cm} (5.15)

Then the conditions on $\kappa$ stated in the beginning of this proof are satisfied. For every $\sigma \in H^m$ we shall prove the equality of left ideals of $B_m$,

$$\tilde{I}_{\sigma \circ \kappa, \sigma(\delta)} = \tilde{I}_{\sigma \circ \mu, \sigma(\delta)}. \hspace{1cm} (5.16)$$

Theorem 5.3 will then follow. Denote $\delta = \sigma(\delta)$. Then by our choice of $\kappa$ we have

$$\sigma \circ \kappa = \sigma \circ \mu + n \delta/2 \hspace{1cm} (5.17)$$

where the sequence $\delta$ is regarded as a weight of $f_m$, by identifying the weights with their sequences of labels. Let $a$ run through $1, \ldots, m$. If $\delta_a = 1$ then by the definition (2.6),

$$\zeta_n(F_{-\bar{a},-\bar{a}}) - n/2 = -\sum_{k=1}^{n} x_{\bar{a}k} \partial_{\bar{a}k} \in I_\delta.$$ 

If $\delta_a = -1$ then the same definition (2.6) implies that

$$\zeta_n(F_{-\bar{a},-\bar{a}}) + n/2 = \sum_{k=1}^{n} \partial_{\bar{a}k} x_{\bar{a}k} \in I_\delta.$$ 

Hence the relation (5.17) implies the equality (5.16). \hspace{1cm} $\square$

Consider the quotient vector space $B_m / I_{\mu,\delta}$ for any sequence $\delta$. The algebra $U(f_m)$ acts on this quotient via left multiplication, being regarded as a subalgebra of $B_m$. The algebra $X(g_n)$ also acts on this quotient via left multiplication, using the homomorphism $\beta_m : X(g_n) \to B_m$. Recall that in Section 2, the target algebra $B_m$ of the homomorphism $\beta_m$ was defined as $U(f_m) \otimes GD(C^m \otimes C^n)$. Here we use a different presentation of the same algebra, by means of the cross relations (4.10). In particular, here the image of $\beta_m$ commutes with the subalgebra $U(f_m)$ of $B_m$; see Proposition 2.3, Part (ii). Thus here the vector space $B_m / I_{\mu,\delta}$ becomes a bimodule over $f_m$ and $X(g_n)$.

Consider the bimodule $F_{\delta}(M_\mu)$ over $f_m$ and $X(g_n)$, defined in the beginning of this section. This bimodule is equivalent to $B_m / I_{\mu,\delta}$. Indeed, let $Z$ run through $GD(C^m \otimes C^n)$. Then a bijective linear map
\[ F_\delta(M_\mu) \to B_m / I_{\mu, \delta} \]

 intertwining the actions of \( f_m \) and \( X(\mathfrak{g}_n) \) can be defined by mapping the element

\[ 1_\mu \otimes Z \in M_\mu \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n) \]

to the image of

\[ \varpi^{-1}(Z) \in \mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n) \subset B_m \]

in the quotient \( B_m / I_{\mu, \delta} \). The intertwining property here follows from the definitions of \( F_\delta(M_\mu) \) and \( I_{\mu, \delta} \). The same mapping determines a bijective linear map

\[ F_\delta(M_\mu) \to \overline{B}_m / I_{\mu, \delta}. \quad (5.18) \]

In particular, the space \( F_\delta(M_\mu)_n \) of \( n \)-coinvariants of \( F_\delta(M_\mu) \) is equivalent to the quotient \( J \setminus \overline{B}_m / I_{\mu, \delta} \) as a bimodule over the Cartan subalgebra \( \mathfrak{h} \subset f_m \) and over \( X(\mathfrak{g}_n) \). But Theorem 5.3 implies that the operator \( \xi_\sigma \) on \( J \setminus \overline{B}_m \) determines a linear map

\[ J \setminus \overline{B}_m / I_{\mu, \delta} \to J \setminus \overline{B}_m / I_{\sigma \circ \mu, \sigma(\delta_+)} \]. \quad (5.19) \]

The latter map intertwines the actions of \( X(\mathfrak{g}_n) \) on the source and the target vector spaces, because the image of \( X(\mathfrak{g}_n) \) in \( B_m \) relative to \( \beta_m \) commutes with the subalgebra \( U(f_m) \subset B_m \); see the definition (4.13). We also use Lemma 4.1, Part (ii). Recall that \( F_m(V) = F_{\delta_+}(V) \). Hence by using the equivalences (5.18) for the sequences \( \delta = \delta_+ \) and \( \delta = \sigma(\delta_+) \), the operator (5.19) becomes the desired \( X(\mathfrak{g}_n) \)-intertwining operator (5.4).

As usual, for any \( f_m \)-module \( V \) and any element \( \lambda \in \mathfrak{h}^* \) let \( V^\lambda \subset V \) be the subspace of vectors \textit{of weight} \( \lambda \), so that any \( X \in \mathfrak{h} \) acts on \( V^\lambda \) via multiplication by \( \lambda(X) \in \mathbb{C} \). It now follows from the property (4.23) of \( \xi_\sigma \) that the restriction of our operator (5.4) to the subspace of weight \( \lambda \) is an \( X(\mathfrak{g}_n) \)-intertwining operator

\[ F_m(M_\mu)_n^\lambda \to F_\delta(M_{\sigma \circ \mu})_{n}^{\sigma \circ \lambda} \quad \text{where} \quad \delta = \sigma(\delta_+). \quad (5.20) \]

At the end of Section 2, we defined the modules \( P_z \) and \( P'_z \) over the Yangian \( Y(\mathfrak{gl}_n) \). The underlying vector space of these modules is the Grassmann algebra \( \mathcal{G}(\mathbb{C}^n) \). This algebra is graded by 0, 1, \ldots, \( n \). The actions of \( Y(\mathfrak{gl}_n) \) on \( P_z \) and \( P'_z \) preserve the degree. Now for any \( N = 1, \ldots, n \) denote respectively by \( P_z^N \) and \( P'_z^{-N} \) the submodules in \( P_z \) and \( P'_z \) which consist of the elements of degree \( N \). Note that \( Y(\mathfrak{gl}_n) \) acts on the subspace of \( P_z \) of degree zero trivially, that is via the counit homomorphism \( Y(\mathfrak{gl}_n) \to \mathbb{C} \). That action of \( Y(\mathfrak{gl}_n) \) does not depend on \( z \). It will be convenient to denote by \( P_{z,0}^N \) the vector space \( \mathbb{C} \) with the trivial action of \( Y(\mathfrak{gl}_n) \).

Denote

\[ \nu_a = n/2 + \mu_a - \lambda_a \quad \text{for} \quad a = 1, \ldots, m. \quad (5.21) \]

Suppose that \( \nu_1, \ldots, \nu_m \in \{0, 1, \ldots, n\} \), otherwise the source \( X(\mathfrak{g}_n) \)-module in (5.20) would be zero by Corollary 2.6. Under our assumption, Corollary 2.6 implies that the the source \( X(\mathfrak{g}_n) \)-module in (5.20) is equivalent to

\[ P_{\mu_m+z}^{\nu_m} \otimes P_{\mu_{m-1}+z+1}^{\nu_{m-1}} \otimes \ldots \otimes P_{\mu_1+z+m-1}^{\nu_1} \quad (5.22) \]

pulled back through the automorphism (1.17) of \( X(\mathfrak{g}_n) \), where \( f(u) \) is given by (2.26) and \( z = \mp \frac{1}{2} \). A more general results is stated as Proposition 5.4 below. The tensor product
in (5.22) is that of $Y(\mathfrak{g}_n)$-modules. Then we employ the embedding $Y(\mathfrak{g}_n) \subset Y(\mathfrak{gl}_n)$ and the homomorphism $X(\mathfrak{g}_n) \rightarrow Y(\mathfrak{g}_n)$ defined by (1.18). By using the labels $\rho_1, \ldots, \rho_m$ of the halfsum $\rho$ of the positive roots of $\mathfrak{f}_m$, the tensor product (5.22) can be rewritten as

$$P^{\nu_m}_{\mu_m-\frac{1}{2}+\rho_m} \otimes \cdots \otimes P^{\nu_1}_{\mu_1-\frac{1}{2}+\rho_1}. \quad (5.23)$$

By using the labels $\rho_1, \ldots, \rho_m$ we can also rewrite the product (2.26) as

$$\prod_{a=1}^{m} \frac{u - \mu_a + \frac{1}{2} - \rho_a}{u - \mu_a - \frac{1}{2} - \rho_a}. \quad (5.24)$$

Let us now consider the target $X(\mathfrak{g}_n)$-module in (5.20). For each $a = 1, \ldots, m$ denote

$$\tilde{\mu}_a = \mu|_{\sigma^{-1}(a)|}, \quad \tilde{\nu}_a = \nu|_{\sigma^{-1}(a)|}, \quad \tilde{\rho}_a = \rho|_{\sigma^{-1}(a)|}.$$

The above description of the source $X(\mathfrak{g}_n)$-module in (5.20) can now be generalized to the target $X(\mathfrak{g}_n)$-module, which depends on an arbitrary element $\sigma \in \mathfrak{f}_m$.

**Proposition 5.4.** For $\delta = \sigma(\delta_+)$ the $X(\mathfrak{g}_n)$-module $F_{\delta}(M_{\sigma \circ \mu})_{\sigma \circ \lambda}^{\ast}$ is equivalent to the tensor product

$$P^{\delta_m \tilde{\nu}_m}_{\tilde{\mu}_m-\frac{1}{2}+\tilde{\rho}_m} \otimes \cdots \otimes P^{\delta_1 \tilde{\nu}_1}_{\tilde{\mu}_1-\frac{1}{2}+\tilde{\rho}_1}. \quad (5.25)$$

pulled back through the automorphism (1.17) of $X(\mathfrak{g}_n)$ where $f(u)$ equals (5.24).

**Proof.** First consider the bimodule $F_m(M_{\sigma \circ \mu})_n$ of $\mathfrak{h}$ and $X(\mathfrak{g}_n)$. By Corollary 2.6, this bimodule is equivalent to the tensor product

$$P^{\delta_m \tilde{\nu}_m}_{\tilde{\mu}_m-\frac{1}{2}+\tilde{\rho}_m} \otimes \cdots \otimes P^{\delta_1 \tilde{\nu}_1}_{\tilde{\mu}_1-\frac{1}{2}+\tilde{\rho}_1}. \quad (5.26)$$

pulled back through the automorphism (1.17) of $X(\mathfrak{g}_n)$ where $f(u)$ equals

$$\prod_{a=1}^{m} \frac{u - \delta_a \tilde{\mu}_a + \frac{1}{2} - \delta_a \tilde{\rho}_a}{u - \delta_a \tilde{\mu}_a - \frac{1}{2} - \delta_a \tilde{\rho}_a}. \quad (5.27)$$

For any $a = 1, \ldots, m$ the element $F_{-\tilde{a},-\tilde{a}} \in \mathfrak{h}$ acts on the tensor product (5.26) as

$$n/2 - \deg_a + (\sigma \circ \mu)_a$$

where $\deg_a$ is the degree operator on the $a$-th tensor factor, counting the factors from right to left. It acts on the vector space $G(\mathbb{C}^n)$ of that tensor factor as the Euler operator

$$\sum_{k=1}^{n} x_k \partial_k \in GD(\mathbb{C}^n). \quad (5.28)$$

A bimodule equivalent to $F_{\delta}(M_{\sigma \circ \mu})_n$ can be obtained by pushing forward actions of $\mathfrak{h}$ and $X(\mathfrak{g}_n)$ on (5.26) through the composition of automorphisms (2.30), for every tensor factor with number $a$ such that $\delta_a = -1$. Here we number the $m$ tensor factors of (5.26) by $1, \ldots, m$ from right to left. Then we also have to pull the resulting $X(\mathfrak{g}_n)$-module back through the automorphism (1.17), where the series $f(u)$ equals (5.27). The automorphism (2.30) maps the element (5.28) to
\[ \sum_{k=1}^{n} \partial_k x_k = n - \sum_{k=1}^{n} x_k \partial_k. \]

Hence if \( \delta_a = -1 \), the element \( F_{-\tilde{a}, -\tilde{a}} \in \mathfrak{h} \) acts on the modified tensor product as

\[ -n/2 + (\sigma \circ \mu)_a + \deg_a. \]

By equating the last displayed expression to \((\sigma \circ \lambda)_a\) and by using (5.21) together with the condition \( \delta_a = -1 \), we get the equation \( \deg_a = \tilde{\nu}_a \). But by Lemma 2.7, pushing forward the \( Y(\mathfrak{gl}_n) \)-module \( P_{-\tilde{\nu}_a} \) through the automorphism (2.30) of \( \mathcal{GD}(\mathbb{C}^n) \) yields the same \( Y(\mathfrak{gl}_n) \)-module as pulling back through the automorphism (1.3) of \( Y(\mathfrak{gl}_n) \) where

\[ g(u) = \frac{u - \tilde{\mu}_a + \frac{1}{2} - \tilde{\rho}_a}{u - \tilde{\mu}_a - \frac{1}{2} - \tilde{\rho}_a}. \]

Thus the \( X(\mathfrak{g}_n) \)-module \( F_\delta(M_{\sigma \circ \mu} \otimes G(\mathbb{C}_n)) \) is equivalent to the tensor product (5.25) pulled back through the automorphism (1.17) where the series \( f(u) \) is obtained by multiplying (5.27) by \( g(-u)g(u) \) for each index \( a \) such that \( \delta_a = -1 \); see the definition (1.18). But for any the element \( \sigma \in \mathcal{H}_m \) the product (5.24) equals

\[ \prod_{a=1}^{m} \frac{u - \tilde{\mu}_a + \frac{1}{2} - \tilde{\rho}_a}{u - \tilde{\mu}_a - \frac{1}{2} - \tilde{\rho}_a}. \quad (5.29) \]

If \( \delta_a = -1 \) then the factors of (5.27) and (5.29) indexed by \( a \) are equal to \( g(-u)^{-1} \) and \( g(u) \) respectively. If \( \delta_a = 1 \) then the factors of (5.27) and (5.29) indexed by \( a \) coincide. This comparison of (5.27) and (5.29) completes the proof. \( \square \)

The vector spaces of two equivalent \( X(\mathfrak{g}_n) \)-modules in Proposition 5.4 are

\( (M_{\sigma \circ \mu} \otimes G(\mathbb{C}_m \otimes \mathbb{C}^n))_{\sigma \circ \lambda} \) and \( G^{\tilde{\nu}_1}(\mathbb{C}_n) \otimes \ldots \otimes G^{\tilde{\nu}_m}(\mathbb{C}_n) \)

respectively. We can define a linear map from the latter vector space to the former, by mapping \( f_1 \otimes \ldots \otimes f_m \) to the class of \( 1_{\sigma \circ \mu} \otimes f \) in the space of \( n \)-coinvariants. Here

\[ f_1 \in G^{\tilde{\nu}_1}(\mathbb{C}_n), \ldots, f_m \in G^{\tilde{\nu}_m}(\mathbb{C}_n) \]

and \( f \in G(\mathbb{C}_m \otimes \mathbb{C}^n) \) is defined by (2.28). This linear map is an equivalence of the \( X(\mathfrak{g}_n) \)-modules in Proposition 5.4, see the remarks made after our proof of Corollary 2.6.

Thus for any \( \nu_1, \ldots, \nu_m \in \{0, 1, \ldots, n\} \) we have demonstrated how the Zhelobenko operator \( \xi_\sigma \) on \( J \setminus B_m \) determines an intertwining operator between the \( X(\mathfrak{g}_n) \)-modules (5.23) and (5.25) pulled back via the automorphism (1.17) of \( X(\mathfrak{g}_n) \), where \( f(u) \) is the same (5.24) for both modules. Hence this operator also intertwines the \( X(\mathfrak{g}_n) \)-modules.
an intertwining operator between them is unique up to a multiplier from $\mathcal{G}$. It was proved in [MN] that both $X(g_n)$-modules in (5.30) are irreducible under our assumptions on $\mu$. Hence an intertwining operator between them is unique up to a multiplier from $\mathcal{C}$. For our intertwining operator, this multiplier is determined by Proposition 5.9 below. Another expression for an intertwining operator of the $X(g_n)$-modules (5.30) was given in [N].

For any $a = 1, \ldots, m$ and $s = 1, \ldots, n$ let us define the elements $f_{as}$ and $g_{as}$ of the ring $\mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)$ as follows. Let us arrange the indices $1, \ldots, n$ into the sequence

$$1, 3, \ldots, n-1, n, \ldots, 4, 2 \quad \text{or} \quad 1, 3, \ldots, n-2, n, n-1, \ldots, 4, 2 \quad (5.31)$$

when $n$ is even or odd respectively. The mapping $k \mapsto \bar{k}$ reverses the sequence (5.31). We will write $i < j$ when $i$ precedes $j$ in this sequence. Note that then the elements $E_{ij} - \theta_i \theta_j E_{\bar{j} \bar{i}} \in \mathfrak{g}l_n$ with $i < j$ or $i = j$ span a Borel subalgebra of $\mathfrak{g}n \subset \mathfrak{g}l_n$, while the elements $E_{ii} - E_{\bar{i} \bar{i}}$ span the corresponding Cartan subalgebra of $\mathfrak{g}n$. Then $f_{as}$ and $g_{as}$ are the products of the elements $x_{ak}$ and $\partial_{ak}$ of $\mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)$ respectively, taken over the first $s$ indices $k$ in the sequence (5.31). For example, if $n \geq 4$ then $f_{a2} = x_{a1}x_{a3}$ and $g_{a2} = \partial_{a2}\partial_{a4}$. If $n = 3$ then $f_{a2} = x_{a1}x_{a3}$ but $g_{a2} = \partial_{a2}\partial_{a3}$. We also set $f_{a0} = g_{a0} = 1$.

Our proof of Proposition 5.9 will be based on the following four lemmas. The proof of the first lemma is very similar to the proof of the second one, and will be omitted.

**Lemma 5.5.** For any $a = 1, \ldots, m-1$ and $s, t = 0, 1, \ldots, n$ the operator $\bar{\xi}_a$ on $J \setminus B_m$ maps the image in $J \setminus B_m$ of $g_{\pi s}g_{a+1}^{-1}t \in B_m$ to the image in $J \setminus B_m$ of the product

$$\bar{\sigma}_a(g_{\pi s}g_{a+1}^{-1}t) \cdot \begin{cases} \frac{H_a - s + t + 1}{H_a + 1} & \text{if } s < t, \\ \frac{H_a + s - t + 1}{H_a + 1} & \text{if } s \geq t, \end{cases}$$

plus the images in $J \setminus B_m$ of elements of the left ideal in $B_m$ generated by $J'$ and (5.5).

**Lemma 5.6.** For any $a = 1, \ldots, m-1$ and $s, t = 0, 1, \ldots, n$ the operator $\bar{\xi}_a$ on $J \setminus B_m$ maps the image in $J \setminus B_m$ of $f_{\pi s}f_{a+1}^{-1}t \in B_m$ to the image in $J \setminus B_m$ of the product

$$\bar{\sigma}_a(f_{\pi s}f_{a+1}^{-1}t) \cdot \begin{cases} \frac{H_a - s + t + 1}{H_a + 1} & \text{if } s > t, \\ \frac{H_a + s - t + 1}{H_a + 1} & \text{if } s \leq t, \end{cases}$$

plus the images in $J \setminus B_m$ of elements of the left ideal in $B_m$ generated by $J'$ and (5.6).

**Proof.** By the definitions (2.6) and (4.6), we have

$$\zeta_n(E_a) = - \sum_{k=1}^{n} x_{a+1}k \partial_{\pi k} \quad \text{and} \quad \zeta_n(F_a) = - \sum_{k=1}^{n} x_{\pi k} \partial_{\pi+1}k. \quad (5.32)$$

By (4.5), we also have

$$\bar{\sigma}_a(f_{\pi s}f_{a+1}^{-1}t) = f_{a+1}^{-1}s f_{\pi t}. $$
Let us now use the symbol \( \equiv \) to indicate equalities in the vector space \( \mathcal{J} \setminus \mathcal{B}_m \) modulo the subspace, which is the image of the left ideal in \( \mathcal{B}_m \) generated by \( \mathcal{J}' \) and by the elements (5.6). The element \( E_a \in \mathcal{B}_m \) belongs to this left ideal. Therefore the operator \( \tilde{\xi}_a \) maps the image in \( \mathcal{J} \setminus \mathcal{B}_m \) of \( f_{\pi s} f_{a+1} f_{\pi t} \in \mathcal{B}_m \) to the image in \( \mathcal{J} \setminus \mathcal{B}_m \) of

\[
\tilde{\xi}_a (f_{\pi s} f_{a+1} f_{\pi t}) = \sum_{r=0}^{\infty} (r! H_a^{(r)})^{-1} E_r^{\alpha} (f_{\alpha+1} f_{\pi t})
\]

\[
\equiv \sum_{r=0}^{\infty} (r! H_a^{(r)})^{-1} \hat{E}_r^{\alpha} (f_{\alpha+1} f_{\pi t}).
\]

Let us now use (4.10) along with (5.32). By the definitions of \( f_{\pi s} f_{a+1} f_{\pi t} \) we have

\[
\hat{F}_a (f_{\alpha+1} f_{\pi t}) = - \sum_{k=1}^{n} [x_{a k} \partial_{a+1 k}, f_{\alpha+1} f_{\pi t}].
\]

If \( s \leq t \), then every summand above is zero, which proves the lemma in this case. Now suppose that \( s > t \). Then by using the proof of [KN2, Proposition 3.7],

\[
\tilde{\xi}_a (f_{\alpha+1} f_{\pi t}) \equiv \sum_{r=0}^{s-t} \frac{(s-t) \ldots (s-t-r+1)}{H_a \ldots (H_a-r+1)} f_{\alpha+1} f_{\pi t}.
\]

In the last line, the sum of the fractions corresponding to \( r = 0, \ldots, s-t \) equals

\[
\frac{H_a + 1}{H_a - s + t + 1};
\]

this equality can be easily proved by induction on the difference \( s-t \). Therefore

\[
\tilde{\xi}_a (f_{\alpha+1} f_{\pi t}) \equiv \frac{H_a + 1}{H_a - s + t + 1} f_{\alpha+1} f_{\pi t} = f_{\alpha+1} f_{\pi t} \frac{H_a + s - t + 1}{H_a + 1}
\]

as required in the case when \( s > t \). Here we also used the equality in the ring \( \mathcal{B}_m \),

\[
H_a f_{\alpha+1} f_{\pi t} = f_{\alpha+1} f_{\pi t} (H_a + s - t)
\]

which follows from (4.10), since

\[
\zeta_n (H_a) = \zeta_n (F_{a+1, a+1} - F_{a a}) = \sum_{k=1}^{n} (x_{a k} \partial_{a+1 k} - x_{a k} \partial_{a k}). \quad \Box
\]

**Lemma 5.7.** For any \( a = 1, \ldots, m-1 \) and \( s, t = 0, 1, \ldots, n \) the operator \( \tilde{\xi}_a \) on \( \mathcal{J} \setminus \mathcal{B}_m \) maps the image in \( \mathcal{J} \setminus \mathcal{B}_m \) of \( f_{\pi s} g_{a+1} f_{\pi t} \in \mathcal{B}_m \) to the image in \( \mathcal{J} \setminus \mathcal{B}_m \) of the product

\[
\tilde{\sigma}_a (f_{\pi s} g_{a+1} f_{\pi t}) = \begin{cases}
H_a + s + t + 1 & \text{if } s + t > n, \\
H_a + n + 1 & \text{if } s + t \leq n,
\end{cases}
\]

plus the images in \( \mathcal{J} \setminus \mathcal{B}_m \) of elements of the left ideal in \( \mathcal{B}_m \) generated by \( \mathcal{J}' \) and (5.7).
Proof. By (4.5),
\[ \tilde{\sigma}_a (f_{\pi s} g_{a+t}^s) = f_{a+1} g_{\pi t}. \]

Let now us the symbol \( \equiv \) to indicate equalities in \( \mathcal{J} \setminus \mathcal{B}_m \) modulo the subspace, which is the image of the left ideal in \( \mathcal{B}_m \) generated by \( \mathcal{J}' \) and by the elements (5.7). The elements \( E_a - \zeta_n(E_a) \) and \( \zeta_n(F_a) \) of \( \mathcal{B}_m \) belong to this left ideal, see (5.32). Using (4.10), the operator \( \xi_a \) maps the image in \( \mathcal{J} \setminus \mathcal{B}_m \) of \( f_{\pi s} g_{a+t}^s \in \mathcal{B}_m \) to the image in \( \mathcal{J} \setminus \mathcal{B}_m \) of
\[ \begin{align*}
\xi_a (f_{a+1}^s g_{\pi t}) &= \sum_{r=0}^{\infty} (r! H_a^{(r)})^{-1} E_a^r \tilde{F}_a^r (f_{a+1}^s g_{\pi t}) \\
&\equiv \sum_{r=0}^{\infty} (r! H_a^{(r)})^{-1} \zeta_n(E_a)^r \zeta_n(F_a)^r f_{a+1}^s g_{\pi t}.
\end{align*} \]

We have
\[ \zeta_n(F_a) f_{a+1}^s g_{\pi t} = - \sum_{k=1}^{n} x_{\pi k} \partial_{a+1} \bar{g}_{a+1} g_{\pi t} \]
by (5.32). If \( s + t \leq n \), then every summand in the above displayed sum is zero modulo the left ideal of \( \mathcal{B}_m \) generated by the elements (5.7), because then there is no factors \( x_{a+1}^i \) of \( f_{a+1}^s \) and \( \partial_{\pi t} \) of \( g_{\pi t} \) with the same index \( i \). This proves the lemma in this case. Now suppose that \( s + t > n \). Then, by using the proof of \([\text{KN}2, \text{Proposition 3.7}], \)
\[ \xi_a (f_{a+1}^s g_{\pi t}) = \sum_{r=0}^{s+t-n} (s+t-n) \ldots (s+t-n-r+1) \frac{H_a \ldots (H_a-r+1)}{H_a} f_{a+1}^s g_{\pi t} = \]
\[ \frac{H_a+1}{H_a-s-t+n+1} f_{a+1}^s g_{\pi t} = \frac{f_{a+1}^s g_{\pi t} H_a+s+t+1}{H_a+n+1} \]
as required. Here we have also used an equality in the ring \( \mathcal{B}_m \) which follows from (4.10),
\[ H_a f_{a+1}^s g_{\pi t} = f_{a+1}^s \pi g_{\pi t} (H_a+s+t). \]
\[ \square \]

Lemma 5.8. If \( \mathfrak{f}_m = \mathfrak{sp}_{2m} \), then for any \( s = 0, 1, \ldots, n \) the operator \( \xi_m \) on \( \mathcal{J} \setminus \mathcal{B}_m \) maps the image in \( \mathcal{J} \setminus \mathcal{B}_m \) of \( f_{\pi s} \in \mathcal{B}_m \) to the image in \( \mathcal{J} \setminus \mathcal{B}_m \) of the product
\[ \tilde{\sigma}_m (f_{\pi s}) \cdot \begin{cases} 
\frac{H_a+s+1}{H_a+n/2+1} & \text{if } s > n/2, \\
1 & \text{if } s \leq n/2,
\end{cases} \]
plus the images in \( \mathcal{J} \setminus \mathcal{B}_m \) of elements of the left ideal in \( \mathcal{B}_m \) generated by \( \mathcal{J}' \) and (5.8).

Proof. Let \( \mathfrak{f}_m = \mathfrak{sp}_{2m} \). Then \( \mathfrak{g}_n = \mathfrak{sp}_n \), so that the number \( n \) is even. By (4.5), we have
\[ \tilde{\sigma}_m (f_{\pi s}) = g_{\pi s} \quad \text{or} \quad \tilde{\sigma}_m (f_{\pi s}) = (-1)^{s-n/2} g_{\pi s} \]
when \( s \leq n/2 \) or \( s > n/2 \) respectively. Hence it suffices to consider for any \( s = 0, 1, \ldots, n \) the image in \( \mathcal{J} \setminus \mathcal{B}_m \) of the element \( \xi_m (g_{\pi s}) \in \mathcal{B}_m \). By the definitions (2.6) and (4.8),
\[
\zeta_n(E_m) = \sum_{k=1}^{n} \theta_k \partial_{\mu_k} \partial_{\nu_k} / 2 \quad \text{and} \quad \zeta_n(F_m) = \sum_{k=1}^{n} \theta_k x_{\mu_k} x_{\nu_k} / 2.
\]

Now let the symbol \( \equiv \) indicate equalities in \( \bar{J} \setminus \bar{B}_m \) modulo the subspace, which is the image of the left ideal in \( \bar{B}_m \) generated by \( \bar{J} \) and by the elements (5.8). The elements \( E_m - \zeta_n(E_m) \) and \( \zeta_n(F_m) \) of \( \bar{B}_m \) belong to this left ideal. Therefore by using (4.10),

\[
\xi_m(g_{m}) = \sum_{r=0}^{\infty} (r! H_m^{(r)})^{-1} E_m^r g_{m} E_m^r (g_{m}) = \sum_{r=0}^{\infty} (r! H_m^{(r)})^{-1} \zeta_n(E_m)^r \zeta_n(F_m)^r g_{m}.
\]

We have

\[
\zeta_n(F_m) g_{m} = \sum_{k=1}^{n} \theta_k x_{\mu_k} x_{\nu_k} g_{m} / 2.
\]

If \( s \leq n/2 \), then every summand in the above sum is zero modulo the left ideal of \( \bar{B}_m \) generated by the elements (5.8), because then for any index \( k \) there is no pair of factors \( \partial_{\mu_k} \) and \( \partial_{\nu_k} \) in the product \( g_{m} \). This proves the lemma in this case. Now suppose that \( s > n/2 \). Then, by using the proof of [KN2, Proposition 3.7] once again, we have

\[
\xi_m(g_{m}) \equiv \sum_{r=0}^{s-n/2} \frac{(s-n/2)\ldots(s-n/2-r+1)}{H_m \ldots (H_m-r+1)} g_{m} E_m =
\]

\[
\frac{H_m + 1}{H_m - s + n/2 + 1} g_{m} = \frac{H_m + s + 1}{H + n/2 + 1}
\]

as required. Here we also used the equality \( H_m g_{m} = g_{m} (H_m + s) \) in the ring \( \bar{B}_m \), which follows from (4.10), because \( m = 1 \) and for \( f_m = \mathfrak{sp}_{2m} \) by (2.6) and (4.8) we have

\[
\zeta_n(H_m) = -\zeta_n(F_1) = n/2 - \sum_{k=1}^{n} x_{1k} \partial_{1k}.
\]

Let us now state Proposition 5.9. We assume that the weight \( \mu \) satisfies the conditions (5.2), and also satisfies the conditions (5.3) in the case \( f_m = \mathfrak{sp}_{2m} \). We also assume that \( \nu_1, \ldots, \nu_m \in \{0, 1, \ldots, n\} \), see the definition (5.21). Let \( (\mu^*_1, \ldots, \mu^*_m) \) be the sequence of labels of the weight \( \mu + \rho \). Thus for each \( a = 1, \ldots, m \) we have \( \mu^*_a = \mu_a + m - a \) in the case \( f_m = \mathfrak{so}_{2m} \), and \( \mu^*_a = \mu_a + m - a + 1 \) in the case \( f_m = \mathfrak{sp}_{2m} \). Let \( (\lambda^*_1, \ldots, \lambda^*_m) \) be the sequence of labels of \( \lambda + \rho \). For each positive root \( \eta = \Delta^+ \) define a number \( z_\eta \in \mathbb{C} \),

\[
z_\eta = \begin{cases}
\lambda^*_b - \lambda^*_c & \text{if } \eta = \varepsilon_b - \varepsilon_c \quad \text{and} \quad \nu_b > \nu_c, \\
\mu^*_b - \mu^*_c & \text{if } \eta = \varepsilon_b + \varepsilon_c \quad \text{and} \quad \nu_b + \nu_c > n, \\
\lambda^*_b + \lambda^*_c & \text{if } \eta = 2\varepsilon_b \quad \text{and} \quad 2\nu_b > n, \\
\mu^*_b & \text{if } \eta = -\varepsilon_b \quad \text{and} \quad \nu_b < n, \\
1 & \text{otherwise}.
\end{cases}
\]
Note that in the first two cases above $1 \leq b < c \leq m$, while in the third case $1 \leq b \leq m$ and $\mathfrak{f}_m = \mathfrak{sp}_{2m}$. Let $v^\lambda_\mu$ be the image of the product $f_{\mathbf{1}_\nu_1} \cdots f_{\mathbf{m}_\nu_m} \in \bar{\mathfrak{B}}_m$ in the quotient vector space $\bar{\mathfrak{J}} \setminus \bar{\mathfrak{B}}_m / \bar{\mathfrak{I}}_{\mu,\delta_+}$. This image is a highest vector relative to the action of the Lie algebra $\mathfrak{g}_n$ on this space: it is annihilated by elements $E_{ij} - \theta_i \theta_j E_{ji} \in \mathfrak{g}_n$ with $i < j$.

**Proposition 5.9.** (i) The vector $v^\lambda_\mu$ is not in the zero coset of $\bar{\mathfrak{J}} \setminus \bar{\mathfrak{B}}_m / \bar{\mathfrak{I}}_{\mu,\delta_+}$.

(ii) Under the action of $\mathfrak{h}$ on $\bar{\mathfrak{J}} \setminus \bar{\mathfrak{B}}_m / \bar{\mathfrak{I}}_{\mu,\delta_+}$ the vector $v^\lambda_\mu$ is of weight $\lambda$.

(iii) For any $\sigma \in \tilde{\mathfrak{S}}_m$ the intertwining operator (5.19) determined by $\xi_\sigma$ maps the vector $v^\lambda_\mu$ to the image in $\bar{\mathfrak{J}} \setminus \bar{\mathfrak{B}}_m / \bar{\mathfrak{I}}_{\sigma \circ \mu,\sigma(\delta_+)}$ of $\bar{\sigma}(f_{\mathbf{1}_\nu_1} \cdots f_{\mathbf{m}_\nu_m}) \in \bar{\mathfrak{B}}_m$ multiplied by the product

$$
\prod_{\eta \in \Delta_\sigma} z_\eta.
$$

(5.33)

**Proof.** Part (i) of the proposition follows directly from the definition of the ideal $\bar{\mathfrak{I}}_{\mu,\delta_+}$. Let us prove Part (ii). The elements of $\mathfrak{h}$ act on $\bar{\mathfrak{J}} \setminus \bar{\mathfrak{B}}_m / \bar{\mathfrak{I}}_{\mu,\delta_+}$ via their left multiplication on $\bar{\mathfrak{B}}_m$. Let us indicate by $\equiv$ the equalities in $\bar{\mathfrak{B}}_m$ modulo the left ideal $\bar{\mathfrak{I}}_{\mu,\delta_+}$. Then by the definition (2.6) for each $a = 1, \ldots, m$ we have the relations in the algebra $\bar{\mathfrak{B}}_m$,

$$
F_{-\bar{a},-\bar{a}} f_{\mathbf{1}_\nu_1} \cdots f_{\mathbf{m}_\nu_m} = f_{\mathbf{1}_\nu_1} \cdots f_{\mathbf{m}_\nu_m} F_{-\bar{a},-\bar{a}} - \sum_{k=1}^{n} [x_{\bar{a}k} \partial_{\bar{a}k} - n/2, f_{\mathbf{1}_\nu_1} \cdots f_{\mathbf{m}_\nu_m}]
$$

$$
= f_{\mathbf{1}_\nu_1} \cdots f_{\mathbf{m}_\nu_m} (F_{-\bar{a},-\bar{a}} - \nu_a) \equiv f_{\mathbf{1}_\nu_1} \cdots f_{\mathbf{m}_\nu_m} (\zeta_n (F_{-\bar{a},-\bar{a}}) + \mu_a - \nu_a)
$$

$$
\equiv x^{\nu_{k_1}}_1 \cdots x^{\nu_{k_n}}_m (n/2 + \mu_a - \nu_a) = \lambda_a f_{\mathbf{1}_\nu_1} \cdots f_{\mathbf{m}_\nu_m}.
$$

Thus

$$
F_{-\bar{a},-\bar{a}} v^\lambda_\mu = \lambda_a v^\lambda_\mu \quad \text{for} \quad a = 1, \ldots, m.
$$

We will prove Part (iii) by induction on the length of a reduced decomposition of $\sigma$ in terms of $\sigma_1, \ldots, \sigma_m$. If $\sigma$ is the identity element of $\tilde{\mathfrak{S}}_m$, then the required statement is tautological. Now suppose that for some $\sigma \in \tilde{\mathfrak{S}}_m$ the statement of (iii) is true. Take any simple reflection $\sigma_a \in \tilde{\mathfrak{S}}_m$ with $1 \leq a \leq m$, such that $\sigma_a \sigma$ has a longer reduced decomposition in terms of $\sigma_1, \ldots, \sigma_m$ than $\sigma$. If $\mathfrak{f}_m = \mathfrak{so}_{2m}$ and $a = m$, then we have $\xi_{\sigma_m} \sigma = \xi_m \sigma$ and $\Delta_{\sigma_m} \sigma = \Delta_\sigma$, so that the induction step is immediate. We may now assume that $a < m$ in the case $\mathfrak{f}_m = \mathfrak{so}_{2m}$.

Take the simple root $\eta_a$ corresponding to the reflection $\sigma_a$. Let $\eta = \sigma^{-1}(\eta_a)$. Then $\eta \in \Delta^+$ and

$$
\sigma_a \sigma(\eta) = \sigma_a(\eta_a) = -\eta_a \notin \Delta^+.
$$

Hence

$$
\Delta_{\sigma_a} \sigma = \Delta_\sigma \sqcup \{\eta\}.
$$

Let $\kappa \in \mathfrak{h}^*$ be the weight with labels (5.15). Using the proof of Theorem 5.3, we get the equality of two left ideals of the algebra $\bar{\mathfrak{B}}_m$,

$$
\bar{\mathfrak{I}}_{(\sigma_a \sigma) \circ \mu, (\sigma_a \sigma)(\delta_+)} = \bar{\mathfrak{I}}_{(\sigma_a \sigma) \circ \kappa, (\sigma_a \sigma)(\delta_+)}.
$$

But modulo the second of these two ideals, the element $H_a$ equals
\((\sigma_a \sigma) \circ \kappa)(H_a) = (\sigma_a \sigma(\kappa + \rho) - \rho)(H_a) = (\kappa + \rho)(\sigma^{-1} \sigma_a(H_a)) - \rho(H_a) =
\]
\[-(\kappa + \rho)(\sigma^{-1}(H_a)) - 1 = -(\kappa + \rho)(H_\eta) - 1 = -\frac{2(\kappa + \rho, \eta)}{\eta, \eta} - 1. \quad (5.34)\]

Here \(H_\eta = \sigma^{-1}(H_a)\) is the coroot corresponding to the root \(\eta\), and we use the standard bilinear form on \(\mathfrak{h}^*\). Using only the definition (5.15), the right hand side of (5.34) equals

\[
-\mu_b^* + \mu_c^* - 1 \quad \text{if} \quad \eta = \varepsilon_b - \varepsilon_c,
\]

\[
-\mu_b^* - \mu_c^* - n - 1 \quad \text{if} \quad \eta = \varepsilon_b + \varepsilon_c,
\]

\[
-\mu_b^* - n/2 - 1 \quad \text{if} \quad \eta = 2\varepsilon_b.
\]

We will now use (iii) as the induction assumption. Denote \(\delta = \sigma(\delta_+)\). Consider five cases.

**I.** Suppose \(\eta = \varepsilon_b - \varepsilon_c\) where \(1 \leq b < c \leq m\), while \(\sigma(\varepsilon_b) = \varepsilon_a\) and \(\sigma(\varepsilon_c) = \varepsilon_{a+1}\). Then \(\sigma_a = \varepsilon_a - \varepsilon_{a+1}\) and \(\delta_a = \delta_{a+1} = 1\). Hence

\[
\bar{\sigma}(f_{1\nu_1} \cdots f_{m\nu_m}) = f_{\nu_b} f_{\rho_{a+1} \nu_c} Y
\]

where \(Y\) is an element of the subalgebra of \(\mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)\) generated by all \(x_{dk}\) and \(\partial_{dk}\) with \(d \neq \pi, a + 1\). Here Lemma 5.6 with \(s = \nu_b\) and \(t = \nu_c\) applies. With these \(s\) and \(t\), by substituting \(-\mu_b^* + \mu_c^* - 1\) for \(H_a\) in the fraction displayed in that lemma, the fraction becomes

\[
\frac{-\mu_b^* + \mu_c^* - 1 + \nu_b - \nu_c + 1}{-\mu_b^* - \mu_c^* - 1 + 1} = \frac{\lambda_b^* - \lambda_c^*}{\mu_b^* - \mu_c^*}. \quad (5.35)
\]

The condition \(s > t\) from Lemma 5.6 means here that \(\nu_b > \nu_c\).

**II.** Suppose \(\eta = \varepsilon_b - \varepsilon_c\) where \(1 \leq b < c \leq m\), but \(\sigma(\varepsilon_b) = -\varepsilon_{a+1}\) and \(\sigma(\varepsilon_c) = -\varepsilon_a\). Then \(\sigma_a = \varepsilon_a - \varepsilon_{a+1}\) again, but \(\delta_a = \delta_{a+1} = -1\). Hence

\[
\bar{\sigma}(f_{1\nu_1} \cdots f_{m\nu_m}) = g_{\nu_c} g_{\rho_{a+1} \nu_b} Y
\]

where \(Y\) is another element of the subalgebra of \(\mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)\) generated by all \(x_{dk}\) and \(\partial_{dk}\) with \(d \neq \pi, a + 1\). Now Lemma 5.5 with \(s = \nu_c\) and \(t = \nu_b\) applies. With these \(s\) and \(t\), by substituting \(-\mu_b^* + \mu_c^* - 1\) for \(H_a\) in the fraction displayed in Lemma 5.5, the fraction becomes the same number (5.35) as in the previous case, under the same condition \(\nu_b > \nu_c\).

**III.** Suppose \(\eta = \varepsilon_b + \varepsilon_c\) and \(1 \leq b < c \leq m\), while \(\sigma(\varepsilon_b) = \varepsilon_a\) and \(\sigma(\varepsilon_c) = -\varepsilon_{a+1}\). Then \(\sigma_a = \varepsilon_a - \varepsilon_{a+1}\) again, but \(\delta_a = 1\) and \(\delta_{a+1} = -1\). Hence

\[
\bar{\sigma}(f_{1\nu_1} \cdots f_{m\nu_m}) = f_{\nu_b} g_{\rho_{a+1} \nu_c} Y
\]

where \(Y\) is another element of the subalgebra of \(\mathcal{G}D(\mathbb{C}^m \otimes \mathbb{C}^n)\) generated by \(x_{dk}\) and \(\partial_{dk}\) with \(d \neq \pi, a + 1\). Here Lemma 5.7 with \(s = \nu_b\) and \(t = \nu_c\) applies. With these \(s\) and \(t\), by substituting \(-\mu_b^* - \mu_c^* - n - 1\) for \(H_a\) in the fraction displayed in that lemma, the fraction becomes the number

\[
\frac{-\mu_b^* - \mu_c^* - n - 1 + \nu_b + \nu_c + 1}{-\mu_b^* - \mu_c^* - n - 1 + n + 1} = \frac{\lambda_b^* + \lambda_c^*}{\mu_b^* + \mu_c^*}. \quad (5.36)
\]

The condition \(s + t > n\) from Lemma 5.7 means here that \(\nu_b + \nu_c > n\).
IV. Suppose \( \eta = \varepsilon_b + \varepsilon_c \) where \( 1 \leq b < c \leq m \), but \( \sigma(\varepsilon_b) = -\varepsilon_{a+1} \) and \( \sigma(\varepsilon_c) = \varepsilon_a \). Then \( \sigma_a = \varepsilon_a - \varepsilon_{a+1} \) again, but \( \delta_a = 1 \) and \( \delta_{a+1} = -1 \). Hence
\[
\bar{\sigma}(f_{1\nu_1} \cdots f_{m\nu_m}) = f_{a\nu_c} g_{a+1\nu_b} Y
\]
where \( Y \) is another element of the subalgebra of \( \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \) generated by \( x_{dk} \) and \( \partial_{dk} \) with \( d \neq \pi, a+1 \). Now Lemma 5.7 with \( s = \nu_c \) and \( t = \nu_b \) applies. With these \( s \) and \( t \), by substituting \( -\mu^*_b - \mu^*_c - n - 1 \) for \( H_a \) in the fraction displayed in that lemma, the fraction becomes the same number (5.36) as in the previous case, under the same condition \( \nu_b + \nu_c > n \).

V. Suppose \( f_m = \mathfrak{sp}_{2m} \) and \( \eta = 2\varepsilon_b \) with \( 1 \leq b \leq m \). Then \( \sigma(\varepsilon_b) = \varepsilon_m \) and \( \sigma_a = \sigma_m \), while \( \delta_m = 1 \). Hence
\[
\bar{\sigma}(f_{1\nu_1} \cdots f_{m\nu_m}) = f_{m\nu_b} Y
\]
where \( Y \) is now an element of the subalgebra of \( \mathcal{GD}(\mathbb{C}^m \otimes \mathbb{C}^n) \) generated by \( x_{dk} \) and \( \partial_{dk} \) with \( d \neq m = 1 \). Here Lemma 5.8 with \( s = \nu_b \) applies. With this \( s \), by substituting \( -\mu^*_b - n/2 - 1 \) for \( H_m \) in the fraction displayed in that lemma, the fraction becomes
\[
\frac{-\mu^*_b - n/2 - 1 + \nu_b + 1}{-\mu^*_b - n/2 - 1 + n/2 + 1} = \frac{\lambda^*_b}{\mu^*_b}.
\]
The condition \( s > n/2 \) from Lemma 5.8 means here that \( 2\nu_b > n \).

Thus in all the five cases above, by using the induction assumption, the intertwining operator
\[
J \backslash B_m / I_{\mu, \delta_+} \rightarrow I_{(\sigma_a \sigma) \circ \mu, (\sigma_a \sigma)(\delta_+)}
\]
determined by \( \bar{\xi} \) maps the vector \( \nu^\lambda_\mu \) to the image in \( J \backslash B_m / I_{(\sigma_a \sigma) \circ \mu, (\sigma_a \sigma)(\delta_+)} \) of
\[
\bar{\sigma}_a \bar{\sigma}^a(f_{1\nu_1} \cdots f_{m\nu_m}) \in B_m
\]
multiplied by the product (5.33) over the set \( \Delta_\sigma \), and by an extra factor \( z_\eta \) corresponding to the positive root \( \eta = \sigma^{-1}(\eta_a) \). This makes the induction step.

The product (5.33) in Proposition 5.9 does not depend on the choice of a reduced decomposition of \( \sigma \in \mathfrak{H}_m \) in terms of \( \sigma_1, \ldots, \sigma_m \). The uniqueness of the intertwining operator (5.30) thus provides another proof of the independence of our operator (5.20) on the decomposition of \( \sigma \), not involving Proposition 4.4. Proposition 5.9 also shows that our intertwining operator (5.20) is not zero.

6. Olshanski homomorphism

For a positive integer \( l \), take the vector space \( \mathbb{C}^{n+l} \). In the case of an alternating form on \( \mathbb{C}^n \) choose \( l \) to be even. Let \( e_1, \ldots, e_{n+l} \) be the vectors of the standard basis in \( \mathbb{C}^{n+l} \). Consider the decomposition \( \mathbb{C}^{n+l} = \mathbb{C}^n \oplus \mathbb{C}^l \) where the direct summands \( \mathbb{C}^n \) and \( \mathbb{C}^l \) are spanned by the vectors \( e_1, \ldots, e_n \) and \( e_{n+1}, \ldots, e_{n+l} \) respectively. This defines an embedding of the direct sum \( \mathfrak{gl}_n \oplus \mathfrak{gl}_l \) of Lie algebras to \( \mathfrak{gl}_{n+l} \). As a subalgebra of \( \mathfrak{gl}_{n+l} \), the summand \( \mathfrak{gl}_n \) is spanned by the matrix units \( E_{ij} \in \mathfrak{gl}_{n+l} \) where \( i, j = 1, \ldots, n \). The summand \( \mathfrak{gl}_l \) is spanned by the matrix units \( E_{ij} \) where \( i, j = n+1, \ldots, n+l \).
The subspace $\mathbb{C}^n \subset \mathbb{C}^{n+l}$ comes with a bilinear form chosen in Section 1. Now choose a bilinear form on the subspace $\mathbb{C}^l \subset \mathbb{C}^{n+l}$ in a similar way. Namely, let $i$ be any of the indices $n+1, \ldots, n+l$. If $i-n$ is even, then put $\bar{i} = i-1$. If $i-n$ is odd and $i < n+l$, then put $\bar{i} = i+1$. If $i = n+l$ and $l$ is odd, then put $\bar{i} = i$. Further, put $\theta_i = 1$ or $\theta_i = (-1)^{i-n-1}$ in the case of the symmetric or alternating form on $\mathbb{C}^n$. For any basis vectors $e_i$ and $e_j$ of the subspace $\mathbb{C}^l$ put $\langle e_i, e_j \rangle = \theta_i \delta_{ij}$. Equip the vector space $\mathbb{C}^{n+l}$ with the bilinear form which is the sum of the forms on the direct summands. The forms on $\mathbb{C}^l$ and $\mathbb{C}^{n+l}$ are of the same type (symmetric or alternating) as the form on $\mathbb{C}^n$.

Now consider the subalgebras $\mathfrak{g}_n$, $\mathfrak{g}_l$ and $\mathfrak{g}_{n+l}$ of the Lie algebras $\mathfrak{g}_l$, $\mathfrak{g}_l$ and $\mathfrak{g}_{n+l}$ respectively. We have an embedding of the direct sum $\mathfrak{g}_n \oplus \mathfrak{g}_l$ to the Lie algebra $\mathfrak{g}_{n+l}$, according to our choice of the bilinear forms made above. We also have an embedding of the direct product of Lie groups $G_n \times G_l$ to $G_{n+l}$. Let $C_l$ denote the subalgebra of $G_l$-invariants in the universal enveloping algebra $U(\mathfrak{g}_{n+l})$. Then $C_l$ contains the subalgebra $U(\mathfrak{g}_n) \subset U(\mathfrak{g}_{n+l})$. If $\mathfrak{g}_n = \mathfrak{sp}_n$ then $C_l$ coincides with the centralizer of the subalgebra $U(\mathfrak{sp}_l) \subset U(\mathfrak{sp}_{n+l})$. If $\mathfrak{g}_n = \mathfrak{so}_n$ then $C_l$ is contained in the centralizer of $U(\mathfrak{so}_l) \subset U(\mathfrak{so}_{n+l})$, but may not coincide with the centralizer.

Take the extended twisted Yangian $X(\mathfrak{g}_{n+l})$. The subalgebra of $X(\mathfrak{g}_{n+l})$ generated by

$$S_{ij}^{(1)}, S_{ij}^{(2)}, \ldots \quad \text{where} \quad i, j = 1, \ldots, n$$

is isomorphic to $X(\mathfrak{g}_n)$ as an associative algebra, see [MNO, Section 3.14]. Thus we have a natural embedding $X(\mathfrak{g}_n) \to X(\mathfrak{g}_{n+l})$, let us denote it by $\iota_l$. We also have a surjective homomorphism

$$\pi_{n+l} : X(\mathfrak{g}_{n+l}) \to U(\mathfrak{g}_{n+l}),$$

see (1.22). Note that the composition $\pi_{n+l} \iota_l$ coincides with the homomorphism $\pi_n$.

Further, consider the involutive automorphism $\omega_{n+l}$ of the algebra $X(\mathfrak{g}_{n+l})$, see the definition (1.20). The image of the composition of homomorphisms

$$\pi_{n+l} \omega_{n+l} \iota_l : X(\mathfrak{g}_n) \to U(\mathfrak{g}_{n+l})$$

belongs to subalgebra $C_l \subset U(\mathfrak{g}_{n+l})$. Moreover, together with the subalgebra of $G_{n+l}$-invariants in $U(\mathfrak{g}_{n+l})$, this image generates $C_l$. These two results are due to G. Olshanski [O2], for their detailed proofs see [MO, Section 4]. We will use the composition of the homomorphisms

$$\gamma_l = \pi_{n+l} \omega_{n+l} \iota_l \circ \omega_n.$$  

We will call it the **Olshanski homomorphism**. The images of the homomorphisms $\gamma_l$ and (6.1) in $U(\mathfrak{g}_{n+l})$ coincide. The reason for using the homomorphism $\gamma_l$ rather than the homomorphism (6.1) will become apparent when we state Theorem 6.1.

An irreducible representation of the group $G_n$ is called **polynomial** if it appears as a subrepresentation of some tensor power of the defining representation $\mathbb{C}^n$. According to [W, Sections V.7 and VI.3] the irreducible polynomial representations of the group $G_n$ are parameterized by all the partitions $\nu$ of $N = 0, 1, 2, \ldots$ such that $2
\nu_1' \leq n$ in the case $G_n = Sp_n$, and $\nu_1' + \nu_2' \leq n$ in the case $G_n = O_n$. Here $\nu'$ is the partition conjugate to $\nu$ while $\nu_1', \nu_2', \ldots$ are the parts of $\nu'$. Note that in the case $G_n = O_n$ we still have $2\nu_2' \leq n$. Denote by $W_\nu$ the irreducible polynomial representation of the group $G_n$ corresponding to $\nu$. Let $\nu_1, \nu_2, \ldots$ be the parts of $\nu$. 

Let \( \bar{\nu} \) be the weight of the Lie algebra \( \mathfrak{f}_m \) with the sequence of labels 
\[
(n/2 - \nu'_m, \ldots, n/2 - \nu'_1).
\]

Due to conditions on \( \nu \), the labels \( \bar{\nu}_1, \ldots, \bar{\nu}_m \) of \( \bar{\nu} \) in the case \( \mathfrak{f}_m = \mathfrak{sp}_{2m} \) are integers such that \( \bar{\nu}_1 \geq \ldots \geq \bar{\nu}_m \geq 0 \). In the case \( \mathfrak{f}_m = \mathfrak{so}_{2m} \) either all labels of \( \bar{\nu} \) are integers, or all if they are half-integers. In the case \( \mathfrak{f}_m = \mathfrak{so}_{2m} \) we have \( \bar{\nu}_1 \geq \ldots \geq \bar{\nu}_{m-1} \geq |\bar{\nu}_m| \).

Consider \( \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n) \) as a bimodule over \( \mathfrak{f}_m \) and \( G_n \). Then by [H, Subsection 3.8.9] when \( G_n = Sp_n \), or by [H, Subsection 4.3.5] when \( G_n = O_n \), we have a decomposition
\[
\mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n) = \bigoplus_{\nu} L_\nu \otimes W_\nu
\]
(6.2)
where \( \nu \) ranges over all parameters of irreducible polynomial representations of \( G_n \) such that \( \nu_1 \leq m \). Here \( L_\nu \) is the irreducible \( \mathfrak{f}_m \)-module of the highest weight \( \bar{\nu} \).

Let \( \lambda \) and \( \mu \) be parameters of any irreducible polynomial representations of the groups \( G_{n+l} \) and \( G_l \) respectively. Suppose that \( \lambda_1, \mu_1 \leq m \). Using the action of the group \( G_l \) on \( W_\lambda \) via its embedding to \( G_{n+l} \) (as the second direct factor of the subgroup \( G_n \times G_l \)) consider the vector space 
\[
\text{Hom}_{G_l}(W_\mu, W_\lambda).
\]
(6.3)
The subalgebra \( C_l \subset U(\mathfrak{g}_{n+l}) \) acts on this vector space through the action of \( U(\mathfrak{g}_{n+l}) \) on \( W_\lambda \). In the case \( G_n = Sp_n \), the vector space (6.3) is irreducible under the action of the algebra \( C_l \); see [D, Theorem 9.1.12]. In the case \( G_n = O_n \), the \( C_l \)-module (6.3) is either irreducible or splits to a direct sum of two irreducible \( C_l \)-modules. It is irreducible if \( W_\lambda \) is irreducible as a \( \mathfrak{so}_{n+l} \)-module, that is if \( 2\lambda'_1 \neq n + l \) by [W, Section V.9]. Note that in the case \( G_n = O_n \), the condition \( 2\lambda'_1 \neq n + l \) is sufficient but not necessary for the irreducibility of the \( C_l \)-module (6.3); see [N, Section 1.7].

In any case, the vector space (6.3) is irreducible under joint action of the subalgebra \( C_l \subset U(\mathfrak{g}_{n+l}) \) and of the subgroup \( G_n \subset G_{n+l} \); see again [N, Section 1.7]. Hence the following identifications of bimodules over \( C_l \) and \( G_n \) are unique up to rescaling of their vector spaces:
\[
\text{Hom}_{G_l}(W_\mu, W_\lambda) = \\
\text{Hom}_{G_l}(W_\mu, \text{Hom}_{\mathfrak{f}_m}(L_{\tilde{\lambda}}, \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^{n+l}))) = \\
\text{Hom}_{G_l}(W_\mu, \text{Hom}_{\mathfrak{f}_m}(L_{\tilde{\lambda}}, \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^l) \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n))) = \\
\text{Hom}_{\mathfrak{f}_m}(L_{\tilde{\lambda}}, L_{\tilde{\mu}} \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n)).
\]
(6.4)
We use the decompositions (6.2) for \( n + l \) and \( l \) instead of \( n \), and the identification
\[
\mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^{n+l}) = \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^l) \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n)
\]
(6.5)
of vector spaces. Thus in (6.4), the labels of the weights \( \tilde{\lambda} \) and \( \tilde{\mu} \) of \( \mathfrak{f}_m \) are respectively 
\[
(n/2 + l/2 - \lambda'_m, \ldots, n/2 + l/2 - \lambda'_1) \quad \text{and} \quad (l/2 - \mu'_m, \ldots, l/2 - \mu'_1).
\]

By pulling back via the Olshanski homomorphism \( \gamma_l : X(\mathfrak{g}_n) \to C_l \), the vector space (6.3) becomes a module over the extended twisted Yangian \( X(\mathfrak{g}_n) \). Using the above identifications, the vector space (6.4) than also becomes a module over \( X(\mathfrak{g}_n) \). But the target \( \mathfrak{f}_m \)-module \( L_{\tilde{\mu}} \otimes \mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^n) \) in (6.4) coincides with the \( \mathfrak{f}_m \)-module \( F_m(L_{\tilde{\mu}}) \).
Theorem 6.1. The action of $X(\mathfrak{g}_n)$ on the vector space (6.4) via the homomorphism $\gamma_l$ coincides with the action, obtained by pulling the action of $X(\mathfrak{g}_n)$ on the bimodule $F_m(L_\bar{\mu})$ back through the homomorphism (1.17) where

$$f(u) = 1 - m(u - l/2 \pm 1/2)^{-1}. \quad (6.6)$$

Proof. Take the action of the subalgebra $C_l \subset U(\mathfrak{gl}_{n+l})$ on the space $\mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^{n+l})$. The extended twisted Yangian $X(\mathfrak{g}_n)$ acts on this vector space via the homomorphism $\gamma_l : X(\mathfrak{g}_n) \to C_l$. Using the decomposition (6.5) we will show that for $i, j = 1, \ldots, n$ the generators $S_{ij}^{(1)}, S_{ij}^{(2)}, \ldots$ of $X(\mathfrak{g}_n)$ act on this vector space respectively as the coefficients at $u^{-1}, u^{-2}, \ldots$ of the series (2.8) multiplied by the series (6.6).

For any $i, j = 1, \ldots, n + l$ the element $F_{ij} \in U(\mathfrak{gl}_{n+l})$ acts on $\mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^{n+l})$ as the operator

$$\sum_{c=1}^m (x_{ci} \partial_{cj} - \theta_i \theta_j x_{cj} \partial_{ci}).$$

Here we use the standard coordinate functions $x_{ci}$ on $\mathbb{C}^m \otimes \mathbb{C}^{n+l}$ with $c = 1, \ldots, m$ and $i = 1, \ldots, n + l$. Then $\partial_{ci}$ is the left derivation on the Grassmann algebra $\mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^{n+l})$ relative to $x_{ci}$. The functions $x_{ci}$ with $c \leq n$ and $c > n$ correspond to the direct summands $\mathbb{C}^n$ and $\mathbb{C}^l$ of $\mathbb{C}^{n+l}$. Consider the $(n+l) \times (n+l)$ matrix whose $i,j$ entry is

$$\delta_{ij} + (u - l/2 \pm 1/2)^{-1} \sum_{c=1}^m (x_{ci} \partial_{cj} - \theta_i \theta_j x_{cj} \partial_{ci}).$$

Write this matrix and its inverse as the block matrices

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} \tilde{A} & \tilde{B} \\ \tilde{C} & \tilde{D} \end{bmatrix}$$

where the blocks $A, B, C, D$ and $\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D}$ are matrices of sizes $n \times n, n \times l, l \times n, l \times l$ respectively. The action of the algebra $X(\mathfrak{g}_n)$ on the vector space $\mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^{n+l})$ via the homomorphism $\gamma_l : X(\mathfrak{g}_n) \to C_l$ can now be described by assigning to the series $S_{ij}(u)$ with $i, j = 1, \ldots, n$ the $i,j$ entry of the matrix $\tilde{A}^{-1}$.

Introduce the $(n+l) \times 2m$ matrix whose $i,c$ entry for $c = -m, \ldots, -1$ is the operator of the left multiplication by $x_{ci}$ on $\mathcal{G}(\mathbb{C}^m \otimes \mathbb{C}^{n+l})$. For $c = 1, \ldots, m$ let the $i,c$ entry of this matrix be the operator $\theta_i \partial_{ci}$. Write this matrix as

$$\begin{bmatrix} P \\ \bar{P} \end{bmatrix}$$

where the blocks $P$ and $\bar{P}$ are matrices of sizes $n \times 2m$ and $l \times 2m$ respectively. Further, introduce the $2m \times (n+l)$ matrix whose $c,j$ entry for $c = -m, \ldots, -1$ is the operator $\partial_{cj}$. For $c = 1, \ldots, m$ let the $c,j$ entry of this matrix be the operator of left multiplication by $\theta_j x_{cj}$. Write this matrix as

$$\begin{bmatrix} Q & \bar{Q} \end{bmatrix}$$

where $Q$ and $\bar{Q}$ are matrices of sizes $2m \times n$ and $2m \times l$ respectively. Then
\[
\begin{bmatrix}
A & B \\
C & D
\end{bmatrix} = 1 + (u - l/2 \pm 1/2)^{-1}
\begin{bmatrix}
PQ - m & PQ \\
\bar{P}Q & P\bar{Q} - m
\end{bmatrix}
\]

which can be also written as the matrix

\[
1 + (u - l/2 \pm 1/2 - m)^{-1}
\begin{bmatrix}
PQ & PQ \\
\bar{P}Q & P\bar{Q}
\end{bmatrix}
\]

multiplied by the series \(f(u)\) determined by (6.6). Using a well known formula for \(\bar{A}^{-1}\),

\[
\bar{A}^{-1} = A - BD^{-1}C = f(u) \left( 1 + (u - l/2 \pm 1/2 - m)^{-1} PQ \right) - \left( u - l/2 \pm 1/2 - m \right)^{-2} P\bar{Q} \left( 1 + (u - l/2 \pm 1/2 - m)^{-1} \bar{P}\bar{Q} \right)^{-1} \bar{P}Q
\]

\[= f(u) \left( 1 + P(u - l/2 \pm 1/2 - m + \bar{Q}\bar{P})^{-1} Q \right). \quad (6.7)
\]

Consider the \(2m \times 2m\) matrix \(\bar{Q}\bar{P}\) appearing in the last line. For any indices \(a, b = -m, \ldots, -1, 1, \ldots, m\) the \(a, b\) entry of this matrix is the operator

\[
\delta_{ab} l/2 \pm \tilde{\zeta}_l(F_{ab})
\]

where \(\tilde{\zeta}_l : U(f_m) \to GD(C^m \otimes \mathbb{C}^{n+l})\) is the homomorphism corresponding to the action of the Lie algebra \(f_m\) on \(G(C^m \otimes \mathbb{C}^{n+l})\) via the tensor factor \(G(C^m \otimes \mathbb{C}^l)\) in (6.5), similar to the homomorphism (2.6). Namely for \(a, b = 1, \ldots, m\) we have

\[
\tilde{\zeta}_l(F_{ab}) = -\delta_{ab} l/2 + \sum_{k=n+1}^{n+l} x_{ak} \partial_{bk},
\]

\[
\tilde{\zeta}_l(F_{a,-b}) = \sum_{k=n+1}^{n+l} \theta_k x_{ak} x_{bk}, \quad \tilde{\zeta}_l(F_{-a,b}) = \sum_{k=n+1}^{n+l} \theta_k \partial_{ak} \partial_{bk}.
\]

Hence any entry of the \(2m \times 2m\) matrix

\[
(u - l/2 \pm 1/2 - m + \bar{Q}\bar{P})^{-1}
\]

can be obtained by applying the homomorphism \(\tilde{\zeta}_l\) to the respective entry of the matrix \(F(u \pm \frac{1}{2} - m)\); the latter entries are series in \(u^{-1}\) with coefficients in \(U(f_m)\). We now complete the proof by comparing the \(i, j\) entry of the \(n \times n\) matrix (6.7) with the series, obtained from (2.8) by replacing \(F_{ab}(u \pm \frac{1}{2} - m)\) there by \(\tilde{\zeta}_l(F_{ab}(u \pm \frac{1}{2} - m))\) for all indices \(a, b = -m, \ldots, -1, 1, \ldots, m\). \(\square\)

Set \(C_0 = U(g_n)\) and \(\gamma_0 = \pi_n\). Then Theorem 6.1 remains valid in the case \(l = 0\). In this case we assume that \(g_0 = \{0\}\). Note that our proof of Theorem 6.1 also implies Proposition 2.3, because the kernels of homomorphisms \(\tilde{\zeta}_l\) with \(l = 0, 1, 2, \ldots\) have only zero intersection. For \(f_m = \mathfrak{so}_2\) the latter follows directly from the definition (2.6). For \(f_m \neq \mathfrak{so}_2\) all irreducible finite-dimensional \(f_m\)-modules arise from the skew Howe duality.

Let \(\lambda\) and \(\mu\) be the parameters of any irreducible polynomial representations of \(G_{n+l}\) and \(G_l\) respectively. The vector space (6.3) is not zero if and only if
\[
\lambda_k \geq \mu_k \quad \text{and} \quad \lambda'_k - \mu'_k \leq n \quad \text{for every} \ k = 1, 2, \ldots ;
\]
(6.8)

see [N, Section 1.3]. Suppose that \(\lambda_1, \mu_1 \leq m\). Then we can identify the vector spaces (6.3) and (6.4). Then the algebra \(C_l\) acts on (6.4) irreducibly, if \(G_n = \text{Sp}_n\). If \(G_n = O_n\), then (6.4) is irreducible under the joint action of the algebra \(C_l\) and the group \(O_n\). In both cases, the \(G_{n+l}\)-invariant elements of \(U(\mathfrak{gl}_{n+l})\) act on (6.4) via multiplication by scalars. Then Theorem 6.1 has a corollary, which refers to the action of \(X(\mathfrak{g}_n)\) on the vector space (6.4) inherited from the bimodule \(F_m(L_{\bar{\mu}})\).

Corollary 6.2. The algebra \(X(\mathfrak{g}_n)\) acts on space (6.4) irreducibly, if \(G_n = \text{Sp}_n\). If \(G_n = O_n\), the space (6.4) is irreducible under the joint action of \(X(\mathfrak{g}_n)\) and \(O_n\).

Now suppose that \(f_m \neq \mathfrak{so}_2\). Then any irreducible finite-dimensional module \(V\) of \(f_m\) is equivalent to \(L_{\bar{\mu}}\) for some non-negative integer \(l\) and the label \(\mu\) of some irreducible polynomial representation of the group \(G_l\) with \(\mu_1 \leq m\). If \(V'\) is another irreducible finite-dimensional \(f_m\)-module, such that the vector space (0.10) is non-zero, then \(V'\) has to be equivalent to \(L_{\bar{\lambda}}\) for the label \(\lambda\) of some irreducible polynomial representation of \(G_{n+l}\) with \(\lambda_1 \leq m\). Thus any non-zero vector space (0.10) has to be of the form (6.4).

Acknowledgments

We are grateful to P. Kulish for amiable attention to this work. The first author has been supported by the RFBR grant 08-01-02934, the grant for Support of Scientific Schools 8065-2006-2, by the Atomic Energy Agency of the Russian Federation, and by the ANR grant 05-BLAN-0029-01. The second author has been supported by the EPSRC grant C511166, and by the EC grant MRTN-CT2003-505078. This work began when both authors visited the Max Planck Institute for Mathematics in Bonn. We are grateful to the staff of the institute for their kind help and generous hospitality.
