(Dated: August 12, 2018)

The existence of pseudomagnetic helicons is predicted for strained Dirac and Weyl materials. The corresponding collective modes are reminiscent of the usual helicons in metals in strong magnetic fields but can exist even without a magnetic field due to a strain-induced background pseudomagnetic field. The properties of both pseudomagnetic and magnetic helicons are investigated in Weyl matter using the formalism of the consistent chiral kinetic theory. It is argued that the helicon dispersion relations are affected by the electric and chiral chemical potentials, the chiral shift, and the energy separation between the Weyl nodes. The effects of multiple pairs of Weyl nodes are also discussed. A simple setup for experimental detection of pseudomagnetic helicons is proposed.

I. INTRODUCTION

Electromagnetic collective excitations play an important role in various plasmas ¹ including relativistic ones. The latter are usually studied in the context of the early universe ², the relativistic heavy-ion collisions ³,⁴, and the degenerate states of dense matter in compact stars ⁵. Since the low-energy quasiparticle excitations in the recently discovered Dirac ⁶,⁷ and Weyl ⁸,⁹,₁₀,₁¹ materials are described by the massless Dirac/Weyl equations, the properties of their collective effects should resemble those in relativistic plasmas. By taking into account that the massless Dirac/Weyl quasiparticles carry a well-defined chirality, an imbalance between the number densities of opposite chiralities. In Weyl and Dirac materials, the pseudomagnetic field can be induced by various types of strains ¹₂,¹₃,¹₄,¹₅. In the case of Cd₃As₂ material, for example, it is estimated that the magnitude of the corresponding field could reach about B₅ ≈ 0.3 T when a static torsion is applied to a nanowire ¹₅ and about B₅ ≈ 15 T when a thin film is bent ²₄. Since Weyl nodes in condensed matter materials always come in pairs of opposite chirality (this stems from the Niesen–Ninomiya theorem ²₅), the pseudomagnetic field by itself does not break the time-reversal symmetry in Weyl materials.

Plasmons are perhaps the best known and characteristic collective excitations in a plasma. They are gapped excitations whose minimal energy is determined by the Langmuir (plasma) frequency. Recently, we showed ²⁶,²⁷ that plasmons in relativistic matter in constant magnetic and pseudomagnetic fields are, in fact, chiral (pseudo)magnetic plasmons. Their chiral nature is manifested in the oscillations of the chiral charge density, which are absent for ordinary electromagnetic plasmons. Moreover, the constant pseudomagnetic field B₅ affects the dependence of plasmon frequencies already in the linear order in the wave-vector. Similar modifications to the energy dispersion of these plasmons can be also induced by the chiral shift parameter b (i.e., the momentum-space separation of the Weyl nodes) in Weyl materials. Interestingly, even in the absence of the chiral shift and external fields, the chiral chemical potential leads to a splitting of the plasmon frequencies in the linear order in the wave vector ²₇.

For a long time it was believed that low-frequency electromagnetic waves cannot propagate in metals. However, the authors of Refs. ²₈,²₉ showed that there exist transverse low-energy gapless excitations propagating along the background magnetic field in uncompensated metals (i.e., metals with different electron and hole densities), which were called helicons. Their counterparts propagating in ionospheres of planets are known as whistlers. The pioneer study of helicons in Weyl materials was performed in Ref. ³₀, where it was shown that the dispersion law of these collective excitations encodes information on the chiral shift parameter b. In this paper, we extend the corresponding study to the case of a background pseudomagnetic field, a nonzero chiral chemical potential, and temperature. The two
FIG. 1. The illustration of two limiting setups for observing helicons. While the usual helicons can be induced in Weyl or Dirac materials in a background magnetic field (left panel), the pseudomagnetic helicons should exist in Weyl or Dirac materials with torsion/strain-induced pseudomagnetic field (right panel).

limiting setups for observing helicons with magnetic $B$ and pseudomagnetic $B_5$ fields are schematically illustrated in the left and right panels in Fig. 1, respectively. Using the consistent chiral kinetic theory, we show that pseudomagnetic helicon can exists in Weyl and Dirac materials under strain.

The paper is organized as follows. The polarization vector and the characteristic equation for the low-energy collective excitations are derived in Sec. II. The pseudomagnetic helicons are analyzed in Sec. III. In Sec. IV we generalize the study of pseudomagnetic helicons to the case of Weyl materials with multiple pairs of Weyl nodes, as well as to the case of Dirac materials. The main results are summarized in Sec. V. In Appendix A, we present the key details of the consistent chiral kinetic theory. Some useful technical formulas and results are given in Appendices B and C.

II. POLARIZATION VECTOR AND CHARACTERISTIC EQUATION

In this section, we use the consistent chiral kinetic theory \[26, 27\] in order to derive the polarization vector and the characteristic equation for the low-energy collective excitations in Weyl materials with one pair of Weyl nodes in an effective background field $B_{0,\lambda} \equiv B_0 + \lambda B_{0,5}$, where $B_0$ is an ordinary magnetic field, $B_{0,5}$ is a strain-induced pseudomagnetic field, and $\lambda = \pm$ is the fermion chirality. It should be noted that the consistent formulation of the chiral kinetic theory amends the original formulation of Refs. \[31–33\] to the case of Weyl materials with a nonzero chiral shift parameter $b$ (odd under time reversal symmetry) and the energy separation between the Weyl nodes $b_0$ (odd under the parity transformation). Moreover, in the presence of pseudoelectromagnetic fields, the consistent formulation of the chiral kinetic theory \[26, 27\] is required by the local conservation of the electric charge. (For similar arguments in the context of quantum field theory, see Refs. \[34, 35\].) Such a formulation is also essential for the correct description of the anomalous Hall effect in Weyl materials \[36–38\], as well as for ensuring the absence of the chiral magnetic effect (CME) current in an equilibrium state of Weyl matter \[35, 39, 40\].

In this study we assume that a Weyl material is subjected only to static background magnetic fields and strains. Therefore, background pseudoelectric and electric fields are absent, $E_0 = E_{0,5} = 0$. Furthermore, for simplicity, we set $B_0 \parallel \hat{z}$ and $B_{0,5} \parallel \hat{z}$, where $\hat{z}$ denotes the unit vector pointing in the $+z$ direction. In addition to the background magnetic and pseudomagnetic fields, collective modes in Weyl materials may induce weak oscillating electromagnetic fields $E'$ and $B'$. As usual in the linear regime \[1, 2\], the corresponding fields take the form of plane waves, i.e.,

$$E' = E e^{-i \omega t + i \mathbf{k} \cdot \mathbf{r}}, \quad B' = B e^{-i \omega t + i \mathbf{k} \cdot \mathbf{r}},$$

with the frequency $\omega$ and the wave vector $\mathbf{k}$. The Maxwell equations imply that $B' = c(k \times E')/\omega$ and

$$\mathbf{k} (\mathbf{k} \cdot \mathbf{E}') - k^2 \mathbf{E}' = -\frac{\omega^2}{c^2} \left( n_0^2 \mathbf{E}' + 4\pi \mathbf{P}' \right),$$

where

$$P^{\prime \prime} = P^{\prime \prime} e^{-i \omega t + i \mathbf{k} \cdot \mathbf{r}} = i \frac{J^{\prime \prime}}{\omega} = \chi^{ml} E'^l$$

is the polarization vector, $J^{\prime \prime}$ is the oscillating part of the current, see Eq. (A10), $\chi^{ml}$ is the electric susceptibility tensor, and $m, l = 1, 2, 3$ denote spatial indices. Further, $n_0$ denotes the material’s background refractive index, which in the case of Dirac semimetal Cd$_3$As$_2$ is $n_0 \approx 6$ \[41\]. In order to simplify our analysis here, we will neglect the
dependence of the refractive index on the frequency. This is well justified for a relatively narrow range of frequencies relevant for helicon modes. From Eqs. (2) and (3) we derive the following characteristic equation:

$$\det \left[ \omega^2 \varepsilon^{lm} - \varepsilon^2 k^2 \delta^{lm} + \varepsilon^2 k^l k^m \right] = 0,$$

where

$$\varepsilon^{lm} = n_0^2 \delta^{lm} + 4\pi \lambda^{lm}$$

is the dielectric tensor. The dielectric tensor $\varepsilon^{lm}$ can be determined by using the consistent chiral kinetic theory. The key details of the corresponding formalism are reviewed in Appendix A. (Note that the fields $E_{\lambda}$ and $B_{\lambda}$ in Appendix A represent the total effective electric and magnetic fields, including the background as well as oscillating ones.) In the study of collective excitations, it is convenient to use the following anazatz for the distribution function

$$f_{\lambda} = f^{(eq)}_{\lambda} + f'_{\lambda},$$

where $f^{(eq)}_{\lambda}$ is the equilibrium distribution function given in Eq. A5, and

$$f'_{\lambda} = f^{(1)}_{\lambda} e^{-i\omega t + ik \cdot r}$$

is a perturbation related to the oscillating fields $E'$ and $B'$. To the leading order in perturbation theory, the chiral kinetic equation (A11) takes the form

$$i \left( [1 + \kappa_{\lambda}]\omega - (\mathbf{v} \cdot \mathbf{k}) - \frac{e}{c} (\mathbf{v} \cdot \Omega_{\lambda})(\mathbf{B}_{0,\lambda} \cdot \mathbf{k}) \right) f^{(1)}_{\lambda} = \frac{e}{c} (\mathbf{v} \times \mathbf{B}_{0,\lambda}) \cdot \partial_{\mathbf{p}} f^{(1)}_{\lambda} = e \left[ (\tilde{E} \cdot \mathbf{v}) + \frac{e}{c} (\mathbf{v} \cdot \Omega_{\lambda})(\tilde{E} \cdot \mathbf{B}_{0,\lambda}) \right] \frac{\partial f^{(eq)}_{\lambda}}{\partial \epsilon_{\mathbf{p}}},$$

where $\Omega_{\lambda} = \lambda e \mathbf{p}/(2p^2)$ is the Berry curvature [12], $p \equiv |\mathbf{p}|$, and $\mathbf{v}$ denotes the quasiparticle velocity, defined in Eq. (A4) with $\mathbf{B}_{\lambda} \rightarrow \mathbf{B}_{0,\lambda}$. In the kinetic equation, we also used the following shorthand notations:

$$\kappa_{\lambda} \equiv \frac{e}{c} (\mathbf{v} \cdot \Omega_{\lambda}) = \lambda \hbar \frac{e (\tilde{p} \cdot \mathbf{B}_{0,\lambda})}{2cp^2},$$

$$\tilde{E} = \mathbf{E} + \frac{\lambda e B_{0,\lambda}}{2c p^2} (\tilde{p} \cdot (\mathbf{k} \times \mathbf{E})), $$

and $\tilde{p} = p/p$. Note that the second term in Eq. (7) originates from the dependence of the quasiparticle dispersion relation on the oscillating part of the magnetic field $B'$; i.e.,

$$\epsilon_{\mathbf{p}} = v_F p \left[ 1 - \frac{e}{c} ((\mathbf{B}_{0,\lambda} + \mathbf{B}') \cdot \Omega_{\lambda}) \right].$$

By making use of the cylindrical coordinates with the $z$-axis pointing along the effective magnetic field $\mathbf{B}_{0,\lambda}$ and $\phi$ being the azimuthal angle of momentum $\mathbf{p}$, Eq. (7) can be rewritten in the following form:

$$\frac{v_F e B_{0,\lambda}}{c p} \partial f^{(1)}_{\lambda} = \frac{\partial f^{(eq)}_{\lambda}}{\partial \epsilon_{\mathbf{p}}},$$

where we dropped all terms quadratic in $B_{0,\lambda}$. Here it is appropriate to recall that, by construction, the chiral kinetic theory is reliable only to the linear order in $B_{0,\lambda}$ [32, 33].

As one can see, Eq. (11) takes the following conventional form (see, e.g., Ref. [2]):

$$\frac{\partial f^{(1)}_{\lambda}}{\partial \phi} + i(a_1 + a_2 \cos \phi) f^{(1)}_{\lambda} = Q(\phi),$$

where the function of the azimuthal angle on the right-hand side is given by

$$Q(\phi) = a_3 \cos(\phi_E - \phi) + a_4 + a_5 \frac{\tilde{p}_\perp \tilde{k}_\parallel + \tilde{p}_\parallel \tilde{k}_\perp \cos \phi}{p^2} \left[ E_{\perp} p_{\perp} k_{\parallel} \sin (\phi - \phi_E) - E_{\parallel} p_{\parallel} k_{\perp} \sin (\phi_E) - E_{\perp} k_{\parallel} p_{\parallel} \sin (\phi) \right],$$

and

$$a_1 = \frac{c p \omega (1 - \kappa_{\lambda})}{e v_F B_{0,\lambda}}, \quad a_2 = \frac{c p \tilde{k}_\perp}{e B_{0,\lambda}}, \quad a_3 = \frac{c p \tilde{k}_\parallel E_{\perp}}{B_{0,\lambda} \epsilon_{\mathbf{p}}}, \quad a_4 = \frac{c p \tilde{E}_{\parallel}}{B_{0,\lambda} \epsilon_{\mathbf{p}}}, \quad a_5 = \frac{i \lambda e v_F}{2\omega B_{0,\lambda} \epsilon_{\mathbf{p}}}. $$
Here subscripts $\parallel$ and $\perp$ denote parallel and perpendicular components of a vector with respect to the magnetic field direction and $\phi_E$ denotes the azimuthal angle of $\mathbf{E}$, which, similarly to $\phi$, is measured from the $\mathbf{k}_\perp$ direction in the plane perpendicular to the magnetic field.

To the linear order in effective magnetic field strength $B_{0,\lambda}$, the equilibrium distribution function $f^{(eq)}_\lambda$ can be expanded as follows:

$$f^{(eq)}_\lambda \approx f^{(0)}_\lambda - \frac{\lambda e v_F \hbar B_{0,\lambda} p_\parallel}{2 p^2 \mathcal{C}} \frac{\partial f^{(0)}_\lambda}{\partial \mathbf{p}} + O(B_{0,\lambda}^2),$$

(15)

where $f^{(0)}_\lambda$ is the equilibrium function $f^{(eq)}_\lambda$ at $B_{0,\lambda} = 0$.

As stated in the Introduction, the main goal of this study is to investigate the spectrum of (pseudo)magnetic helicons in Weyl materials. The corresponding collective excitations are gapless modes closely related to the cyclotron resonances. By following the same approach that is used in nonrelativistic plasmas [2], it is convenient to replace the distribution function $f^{(1)}_\lambda(\phi)$ with a new function,

$$g(\phi) = e^{i a_2 \sin \phi} f^{(1)}_\lambda(\phi),$$

(16)

which, in view of Eq. (12), satisfies the following equation:

$$\frac{\partial g}{\partial \phi} + i a_1 g = e^{i a_2 \sin \phi} Q(\phi).$$

(17)

By taking into account that $g(\phi)$ is a periodic function of the azimuthal angle $\phi$, the solution to Eq. (17) can be obtained in the form of a Fourier series,

$$g(\phi) = \sum_{n=-\infty}^{\infty} g_n e^{i n \phi},$$

(18)

where coefficients $g_n$ are given by

$$g_n = -\frac{i}{2 \pi (a_1 + n)} \int_0^{2 \pi} e^{i a_2 \sin \tau - i n \tau} Q(\tau) d\tau.$$

(19)

Here, the integration over the variable $\tau$ can be performed analytically. The corresponding explicit expressions for $g_n$ are presented in Appendix B.

For gapless collective excitations such as helicons, it is convenient to consider the long-wavelength limit, i.e., $v_F k \ll \Omega_c |p = p^*|$, where $p^* \sim \sqrt{\mu_2^* + \mu_2^* \pi^2 T^2 / v_F}$ is a characteristic momentum in a chiral plasma, and

$$\Omega_c \simeq \frac{e v_F B_{0,\lambda}}{c_\mathcal{P}} + O(B_{0,\lambda}^2)$$

(20)

is an analog of the cyclotron frequency for massless fermions in the (pseudo)magnetic field that depends on momentum $p$. In the long-wavelength limit, the analysis significantly simplifies because one can neglect the dependence of $f^{(1)}_\lambda$ on the wave vector $\mathbf{k}$. Furthermore, by utilizing the same approximation as in Ref. [30], we will include only the lowest three (i.e., $n = 0, \pm 1$) Fourier harmonics in the solution. By using the definitions in Eq. (14) and the explicit expressions for the coefficients $g_n$ in Appendix B, we obtain the following results:

$$f^{(1)}_{\lambda, 0} = -i \frac{e v_F p_\parallel (1 + \kappa_\lambda)}{p \omega} \frac{(\mathbf{E} \cdot \hat{\mathbf{z}})}{\mathcal{C}} \frac{\partial f^{(eq)}_\lambda}{\partial \mathbf{p}},$$

(21)

$$f^{(1)}_{\lambda, \pm} = -i \frac{e v_F p_\perp (1 + \kappa_\lambda)}{2 p} \frac{E_\pm i E_y}{\omega \pm \Omega_c} \frac{\partial f^{(eq)}_\lambda}{\partial \mathbf{p}} e^{\pm i \phi},$$

(22)

for the $n = 0$ and $n = \pm 1$ Fourier harmonics of $f^{(1)}_\lambda$, respectively. By making use of these results, we derive the expression for the polarization vector $\mathbf{P}$, i.e.,

$$\mathbf{P} = \sum_{\lambda = \pm} \sum_{p, a} \frac{i e}{\omega} \int \frac{d^3 p}{(2 \pi \hbar)^3} \left\{ e(E \times \hat{\mathbf{z}} \times \mathbf{E}) + e \frac{(\mathbf{v} \cdot \mathbf{E}) (\mathbf{k} \times \mathbf{E})}{c} + e \frac{(\delta \mathbf{v} \cdot \mathbf{E}) B_{0,\lambda}}{c} \right\} f^{(eq)}_\lambda$$

$$+ \frac{e^2 \hbar v_F}{2 \omega^2} \int \frac{d^3 p_1}{(2 \pi \hbar)^3} \frac{1}{p} [\mathbf{k} \times \mathbf{E}] \frac{\partial f^{(0)}_\lambda}{\partial \mathbf{p}} f^{(eq)}_\lambda + \frac{1}{\omega} \int \frac{d^3 p}{(2 \pi \hbar)^3} \left[ v + e \frac{(\mathbf{v} \cdot \mathbf{E}) B_{0,\lambda}}{c} \right] f^{(1)}_{\lambda, n}$$

$$- \frac{e^3}{2 \pi^2 \omega \hbar^2} \sum_{n = -1}^{1} \sum_{\lambda = \pm} \sum_{p, a} \frac{e}{\omega} \int \frac{d^3 p}{(2 \pi \hbar)^3} \left| e_p f^{(1)}_{\lambda, n} (\mathbf{k} \times \mathbf{E}) - i \frac{e^3}{2 \pi^2 \omega \hbar^2} (\mathbf{b} \times \mathbf{E}) + i \frac{e^3 b_0}{2 \pi^2 \omega \hbar^2} (\mathbf{k} \times \mathbf{E}),$$

(23)
where $\sum_{p,a}$ denotes the summation over contributions of particles and antiparticles (holes), and we used the expression for the current consistent with the local charge conservation [26, 27]. Here,

$$ \delta v = \frac{2ev_F}{c} \hat{p} (\mathbf{B} \cdot \Omega) - \frac{ev_F}{c} B (\hat{p} \cdot \Omega) = \frac{\lambda e v_F}{2 \omega^2} \left\{ 2\hat{p} (\hat{p} \cdot [k \times E]) - [k \times \mathbf{E}] \right\} $$  \hspace{1cm} (24)

is the correction to velocity, which follows from the oscillating magnetic field in the dispersion relation [10]. The details of calculation of the polarization vector $\mathbf{P}$ in the limit of small frequencies $\omega \ll \Omega_{c,p=p^*}$ are given in Appendix C. The final result in the leading order in $B_{0,\lambda}$ takes the following form:

$$ 4\pi \mathbf{P} = A_1 (\mathbf{E} \times \hat{z}) + A_2 (\hat{k} \times \mathbf{E}) + A_3 (\mathbf{b} \times \mathbf{E}) + A_4 (\mathbf{E} - \hat{z}(\mathbf{E} \cdot \hat{k})) + A_5 \hat{z}(\mathbf{E} \cdot \hat{k}), $$ \hspace{1cm} (25)

where

$$ A_1 = \sum_{\lambda=\pm} i \frac{2ec\mu_{\lambda}}{3B_{0,\lambda} v_F^2 \hbar^2 \pi \omega} \left( \mu_{\lambda}^2 + \pi^2 T^2 \right) = i \frac{\hat{A}_1}{\omega}, $$ \hspace{1cm} (26)

$$ A_2 = i \frac{2ke^2 (eb_0 + \mu_5)}{\pi \omega^2 \hbar^2} \equiv i \frac{k\hat{A}_2}{\omega^2}, $$ \hspace{1cm} (27)

$$ A_3 = -i \frac{2e^3}{\pi \omega \epsilon \hbar^2} \equiv i \frac{\hat{A}_3}{\omega}, $$ \hspace{1cm} (28)

$$ A_4 = \sum_{\lambda=\pm} \frac{2e^2}{3\pi \hbar^3 v_F^2 B_{0,\lambda}^2} \left( \mu_{\lambda}^2 + 2\pi^2 \mu_5^2 T^2 + \frac{7\pi^4 T^4}{15} \right), $$ \hspace{1cm} (29)

$$ A_5 = -\sum_{\lambda=\pm} \frac{2e^2}{3\pi \hbar^3 v_F^2 \omega^2} \left( \mu_{\lambda}^2 + \pi^2 T^2 \right) = \frac{\hat{A}_5}{\omega^2}. $$ \hspace{1cm} (30)

At zero temperature, we obtain

$$ \hat{A}_1 \to 0 = \sum_{\lambda=\pm} \frac{2ec\mu_{\lambda}^3}{3\pi \hbar^3 B_{0,\lambda} v_F^2}, $$ \hspace{1cm} (31)

$$ A_4 \to 0 = \sum_{\lambda=\pm} \frac{2e^2 \mu_{\lambda}^4}{3\pi \hbar^3 B_{0,\lambda}^2 v_F^5}, $$ \hspace{1cm} (32)

$$ \hat{A}_5 \to 0 = -\sum_{\lambda=\pm} \frac{2e^2 \mu_{\lambda}^2}{3\pi \hbar^3 v_F^2}. $$ \hspace{1cm} (33)

(Note that the other two coefficients, i.e., $\hat{A}_2$ and $\hat{A}_3$, do not depend on temperature.) Thus, the dielectric tensor [5] reads

$$ \epsilon^{ml} = \delta^{ml} n_0^2 + A_1 \epsilon^{ml3} + A_2 \epsilon^{mlj} \hat{k}^j + A_3 \epsilon^{mlj} \mathbf{b}^j + A_4 (\delta^{ml} - \delta^{m3} \delta^{l3}) + A_5 \delta^{m3} \delta^{l3}. $$ \hspace{1cm} (34)

It is worth noting that contrary to the case of the usual helicons in metals, the dielectric tensor in Weyl materials is modified by the chiral shift $\mathbf{b}$, as can be seen from the fourth term in Eq. [34]. The dielectric tensor is also affected by the pseudomagnetic field $\mathbf{B}_{0,5}$ and the chiral chemical potential $\mu_5$. By taking into account that $b_0 = -\mu_5 / e$ in equilibrium, we find that $\epsilon^{ml}$ is symmetric with respect to the replacement $(\mathbf{B}_{0,5}, \mu_5) \rightarrow (\mathbf{B}_{0,5}, \mu)$. It is also worth noting that the interband (i.e., particle-hole) contributions, which may be important in the optical range, can be ignored in the study of low-energy helicons. In fact, the corresponding effects can be effectively accounted for by renormalizing the background refractive index $n_0$ [39].

It is well known that helicons are absent at $\mathbf{k} \perp \mathbf{B}_0$ [1–4]. Therefore, for simplicity, we can set $\mathbf{k} = (0, 0, k_{||})$. Then, the characteristic equation [4] takes the form

$$ A_1^2 \omega^4 b_1^2 \left( c^2 k_{||}^2 - (n_0^2 + A_4) \omega^2 \right) - (n_0^2 + A_5) \left[ (c^2 k_{||}^2 - (n_0^2 + A_4) \omega^2)^2 + \omega^4 (A_1 - A_2 - b_{||} A_3)^2 \right] = 0. $$ \hspace{1cm} (35)

Before solving this equation, let us briefly discuss the role of coefficients $A_i$ (where $i = 1, 5$). As in the case of usual helicons in metals, the existence of pseudomagnetic ones relies on the off-diagonal components of the dielectric tensor, which are given by coefficients $A_1$, $A_2$, and, in the case of $\mathbf{b} \neq 0$, by $A_3$. The first coefficient is related to the nondissipative Hall conductivity, albeit generalized to the case of nonzero values of the pseudomagnetic field and the chiral chemical potential. The coefficient $A_2$ is proportional to the combination of the energy separation of the
Weyl nodes and the chiral chemical potential, $e b_0 + \mu_5$, that vanishes in equilibrium \[34, 35\]. While in our analysis below we will eventually assume the state of equilibrium, it is interesting to note that the helicon properties could be substantially modified in Weyl materials out of equilibrium, e.g., in steady states with $E_0 \cdot B_0 \neq 0$, which are characterized by $e b_0 + \mu_5 \neq 0$. The third term, $A_3$, is related to the anomalous Hall effect in Weyl materials \[36, 38\]. The other two coefficients, i.e., $A_1$ and $A_2$, affect only diagonal components of the dielectric tensor $\varepsilon_{\mu\nu}$ and, thus, are not crucial for the existence of helicons. However, they could provide quantitative corrections to the dispersion relations of collective excitations.

### III. LOW-ENERGY COLLECTIVE MODES

In this section we study the helicon-type solutions to the characteristic equation \[35\] and investigate their properties. The analysis of the corresponding equation shows that due to the large factor $(n_0^2 + A_5)$, the effect of the chiral shift perpendicular to a background (pseudo)magnetic field $b_{\perp}$ is numerically small for the helicon dispersion relation. Therefore, we consider below only the case $b = (0, 0, b_1)$, which admits simple analytical solutions for the collective excitation frequencies. Then, Eq. \[35\] reduces to the following equation:

$$(n_0^2 \omega^2 - c^2 k^2 + \omega^2 A_1)^2 + \omega^4 (A_1 - A_2 - A_3 b_{\parallel})^2 = 0,$$

where we also dropped the overall factor $(n_0^2 + A_5)$ because the equation $(n_0^2 + A_5) = 0$ has only a high-energy gapped solution with frequency proportional to the Langmuir (plasma) frequency

$$\Omega_c = \sqrt{\frac{4 \alpha}{3 \pi \hbar^2}} \left( \mu^2 + \mu_5^2 + \frac{\pi^2 T^2}{3} \right).$$

Here $\alpha \equiv e^2 / (\hbar v_F)$ is the fine structure constant. In view of our approximation of small $\omega$, this solution is unreliable. The corresponding gapped excitations (namely, the chiral magnetic plasmons) were properly analyzed in Refs. \[26, 27\].

The solutions to Eq. \[35\] are

$$\omega_{\pm} = \pm \frac{\hat{A}_1 - \hat{A}_3 b_{\parallel}}{2(n_0^2 + A_4)} + \frac{4k (c^2 k + \hat{A}_2) (n_0^2 + A_4) + (\hat{A}_3 b_{\parallel} - \hat{A}_1)^2}{2(n_0^2 + A_4)},$$

where coefficients $\hat{A}_1$, $\hat{A}_2$, $\hat{A}_3$, and $A_4$ are given by Eqs. \[26\] through \[30\]. In the long-wavelength limit, we find

$$\omega_+ \simeq \frac{\hat{A}_2 k}{\hat{A}_1 - \hat{A}_3 b_{\parallel}} - \frac{\hat{A}_2 k}{\hat{A}_1 - \hat{A}_3 b_{\parallel}} + k^2 \frac{c^2 |\hat{A}_1 - \hat{A}_3 b_{\parallel}|^2 - \hat{A}_2^2 (n_0^2 + A_4)}{|\hat{A}_1 - \hat{A}_3 b_{\parallel}|^3} + O(k^3),$$

$$\omega_- \simeq \frac{\hat{A}_2 k}{\hat{A}_1 - \hat{A}_3 b_{\parallel}} + k^2 \frac{c^2 |\hat{A}_1 - \hat{A}_3 b_{\parallel}|^2 - \hat{A}_2^2 (n_0^2 + A_4)}{|\hat{A}_1 - \hat{A}_3 b_{\parallel}|^3} + O(k^3).$$

The gapped solution $\omega_+$ is unreliable since it is outside the validity of the low-frequency approximation used in the derivation. The frequency of the gapless mode is physical and corresponds to a helicon, i.e., $\omega_h = \omega_-$. In the limit of zero temperature, $T \to 0$, the corresponding result reads

$$\omega_h \simeq \frac{3k(e b_0 + \mu_5) c e \hbar v_F^2 (B_0^2 - B_{0,5}^2)}{2 B_0 c^2 \mu^2 + 3 \mu_5^2 - 2 B_{0,5} c^2 \mu_5 (\mu_5^2 + 3 \mu_5^2) + 3(B_0^2 - B_{0,5}^2) e^2 \hbar v_F^2 b_{\parallel}} + \frac{3k^2 c^2 \hbar v_F^2 (B_0^2 - B_{0,5}^2)}{2 B_0 c^2 \mu^2 + 3 \mu_5^2 - 2 B_{0,5} c^2 \mu_5 (\mu_5^2 + 3 \mu_5^2) + 3(B_0^2 - B_{0,5}^2) e^2 \hbar v_F^2 b_{\parallel}}$$

$$\omega_h \simeq \frac{9k^2(e b_0 + \mu_5) c e \hbar v_F^2 (B_0^2 - B_{0,5}^2) [B_0^2 (\mu^4 + 6 \mu_5^2 + \mu_5^2) + B_{0,5}^2 (\mu^4 + 6 \mu_5^2 + \mu_5^2) - 8 B_0 B_{0,5} \mu_5 (\mu_5^2 + \mu_5^2)] + 9(B_0^2 + B_{0,5}^2) e^2 \hbar v_F^2 b_{\parallel}}{2 [B_0 \mu^2 + 3 \mu_5^2 - B_{0,5} \mu_5 (\mu_5^2 + 3 \mu_5^2)]^2 [2 B_0 c^2 \mu^2 + 3 \mu_5^2 - 2 B_{0,5} c^2 \mu_5 (\mu_5^2 + 3 \mu_5^2)] + 9(B_0^2 + B_{0,5}^2) e^2 \hbar v_F^2 b_{\parallel}} + O(k^3),$$

(41)
where we kept only the leading and subleading terms in $B_0$ and $B_{0,5}$ in the numerators and denominators. It is instructive to consider two special cases

$$
\omega_h \big|_{B_0,5 \to 0, \mu_5 \to 0} \approx \begin{cases} 
\frac{2b_0B_0c\varepsilon v_F^2 k^2}{\pi c^2 h^2 \mu \Omega^2_c + 2B_0 e^4 v_F^2 b_||} + \frac{eB_0c^2 \pi v_F^2 k^2}{\pi h^2 \Omega^2_c \mu + 2B_0 e^4 v_F^2 b_||} - \frac{4B_0 e^7 v_F^2 k^2 b_0^2}{\pi h^2 \Omega^2_c (\pi c^2 h^2 \mu \Omega^2_c + 6B_0 e^4 v_F^2 b_||)} 
\end{cases}$$

$$
\omega_h \big|_{B_0 \to 0, \mu_\to 0} \approx \begin{cases} 
\frac{2(eb_0 + \mu_5)B_{0,5}\varepsilon v_F^2 k^2}{\pi c^2 h^2 \mu \Omega^2_c + 2B_{0,5} e^4 v_F^2 b_||} + \frac{eB_{0,5}c^2 \pi v_F^2 k^2}{\pi h^2 \Omega^2_c \mu_5 + 2B_{0,5} e^4 v_F^2 b_||} - \frac{4B_{0,5} e^7 v_F^2 k^2 (eb_0 + \mu_5)^2}{\pi h^2 \Omega^2_c (\pi c^2 h^2 \mu_5 \Omega^2_c + 6B_{0,5} e^4 v_F^2 b_||)} 
\end{cases}
$$

(42)

(43)

Note that Eq. (42) agrees with the results obtained in Ref. [30]. It should be emphasized, though, that the default choice of parameters in Ref. [30], i.e., $b_0 \neq 0$ and $\mu_5 = 0$, effectively describes an out-of-equilibrium state of a Weyl plasma. In such a regime, the dispersion is linear in the wave vector. On the other hand, we find that the assumption of equilibrium generically implies a quadratic dispersion relation for the helicon, i.e., it is qualitatively the same as in the usual metals. This is due to the fact that the linear term in Eq. (11) is proportional to $eb_0 + \mu_5$ and, thus, vanishes in equilibrium. In essence, this is the same argument that explains the absence of the CME current in Weyl materials in equilibrium [35, 38, 40].

One of the key predictions of this paper is the existence of a gapless helicon-type mode in a Weyl matter without a magnetic field. It is natural to call the corresponding gapless mode a pseudomagnetic helicon. Indeed, as we see from Eq. (43), a gapless mode can be naturally realized in parity-odd Weyl materials under strain. The corresponding materials are characterized by a strain-induced background pseudomagnetic field $B_{0,5}$ and a nonzero chiral chemical potential $\mu_5$. In equilibrium, the latter is determined by the energy separation between the Weyl nodes, i.e., $\mu_5 = -eb_0$. In such a state of Weyl materials, the helicon has a quadratic dispersion relation, see the second line in Eq. (13). On the other hand, out of equilibrium (e.g., in a steady state with $eb_0 + \mu_5 \neq 0$ produced by external fields with $E_0 \cdot B_0 \neq 0$), a linear dispersion relation could be realized too.

In order to discuss the qualitative properties of the pseudomagnetic helicons, it is convenient to define a characteristic scale for the chiral shift in Weyl materials. To this end, let us introduce the following reference value:

$$eb^* = 0.3 \frac{\pi h v_F}{c_3},$$

(44)

where $c_3 \approx 25.480$ Å is the lattice spacing and $b^*$ is comparable to the momentum space separation between the Dirac points in Cd$_3$As$_2$ [11]. In what follows, we will concentrate only on the equilibrium case $\mu_5 = -eb_0$ with nonzero pseudomagnetic field $B_{0,5}$ and set $B_0 = 0$. Also, in our numerical calculations below, we will use the value of the Fermi velocity of Cd$_3$As$_2$ [11], i.e., $v_F \approx 1.5 \times 10^8$ cm/s. It is expected, of course, that the main qualitative conclusions should remain valid for generic Dirac or Weyl materials.

The effect of the chiral shift parameter $b_0$ on the gapless mode $\omega_h$ is shown in Fig. 2. As one can see, the chiral shift decreases the helicon frequency. Quantitatively, however, the effect is rather weak.

---

FIG. 2. The helicon dispersion relation $\omega_h = \omega_+$ given by Eq. (23) for $b_0 = 0$ (red solid line), $b_0 = 0.5b^*$ (blue dashed line), $b_0 = b^*$ (green dotted line), and $b_0 = 2b^*$ (brown dot-dashed line). We set $B_{0,5} = 10^{-2}$ T, $B_0 = 0$, $\mu_5 = 5$ meV, and $\mu = 0$. 
The helicon dispersion relations at different values of $T$, $B_{0.5}$, $\mu$, and $\mu_5$ are plotted in Figs. 3 through 5. Comparing the left and the right panels in Fig. 3 one can see that the dispersion law of the pseudomagnetic helicons changes from the quadratic form at $\mu_5 \neq 0$, $\mu = 0$, and small $k$ to a linear one at $\mu_5 = 0$, $\mu \neq 0$, and large $k$. In the latter case, the approximate, quadratic in $k$, expression (40) is valid only for small $k$. Moreover, the frequency of the helicon mode in the left panel is a few times lower than in the right one.

Further, we show the dependence of the frequency $\omega_h$ on the wave vector $k$ at different values of chiral and electric chemical potentials in the left and right panels in Fig. 4 respectively. In order to be consistent with the approximation of small pseudomagnetic fields

$$\frac{\hbar v_F^2 |eB_{0.5}|}{\epsilon (\mu_5^2 + \mu^2 + \pi^2T^2)} \ll 1,$$

we consider only relatively small pseudomagnetic fields $B_{0.5} \ll \bar{B}_5$ or sufficiently large electric and chiral chemical potentials $\mu, \mu_5 \gtrsim \bar{\mu}$, where

$$\bar{B}_5 = \frac{c(\mu_5^2 + \mu^2 + \pi^2T^2)}{\epsilon h v_F^2} \approx 6.853 \times 10^{-1}(\mu_5[\text{meV}])^2 \text{T},$$

$$\bar{\mu} = v_F \sqrt{\frac{\hbar |eB_{0.5}|}{c}} \approx 38.198 \sqrt{B_{0.5}[\text{T}]} \text{meV}.$$  

Similarly to the right panel in Fig. 3 the dispersion law of the pseudomagnetic helicons at $\mu_5 = 0$ and $\mu \neq 0$ (right panel) changes from a quadratic one at small $k$ to a linear one at large $k$. The dependence of the frequency $\omega_h$ on the wave vector $k$ at different values of the pseudomagnetic field is shown in the left and right panels in Fig. 4 for $\mu_5 = 5 \text{meV}$, $\mu = 0$ and $\mu_5 = 0$, $\mu = 5 \text{meV}$, respectively. Compared to the quadratic decrease of the helicon frequency with $\mu_5$ and $\mu$, the dependence of $\omega_h$ on $B_{0.5}$ is almost linear. Finally, we would like to note that the results for a finite background magnetic field $\bar{B}_0$ applied to the system with nonzero chemical potential $\mu$ can be obtained by replacing $(B_{0.5}, \mu_5) \rightarrow (B_0, \mu)$.

Up to now we studied helicons in a Weyl material with a single pair of Weyl nodes. However, all experimentally discovered Weyl materials [13–18] have multiple pairs of Weyl nodes. It is natural, therefore, to investigate how the physical properties of helicons are affected by the presence of several pairs of Weyl nodes. Another important question is the existence of the pseudomagnetic helicons in Dirac materials. Naively, by taking into account the topological triviality of a Dirac point, one may simply suggest that there should be no pseudomagnetic field and, thus, no pseudomagnetic helicons in Dirac materials. However, some Dirac semimetals (e.g., $A_3\text{Bi}$ where $A=\text{Na,K,Rb}$) are, in fact, $\mathbb{Z}_2$ Weyl semimetals [42], whose Dirac points come from two superimposed pairs of Weyl nodes with opposite chiral shifts. In such a case, a strain-induced pseudomagnetic field is possible and, as a result, pseudomagnetic helicons can exist. The properties of pseudomagnetic helicons in the case of Weyl and Dirac materials with multiple pairs of Weyl nodes are studied in the next section.
Dirac materials somewhat more complicated. Pseudomagnetic fields of different directions and amplitudes. This makes the analysis of strained multipair Weyl or Eq. (23), but will include an additional sum over the pair index $\xi$ is straightforward to derive the expression for the polarization vector. The final result will have the same form as in view of different orientations of $\mathbf{b}$ separation that, in general, the pairs of Weyl nodes are characterized by different values of the chiral shift $\mu$ represents results obtained for $\mu = 0$, $\mu = 5$ meV, and $\mu = 50$ meV, respectively. The same values, albeit for the electric chemical potential $\mu$, are used in the left panel. The left panel is plotted for $\mu = 0$, while the right one represents results obtained for $\mu = 5$. We set $b_{\parallel} = 0.5 b^*$, $T = 0$, $B_0 = 0$, and $B_{0.5} = 10^{-2}$ T.

FIG. 5. The dispersion relation of the low-energy collective mode $\omega_k = \omega_-$ defined by Eq. (38). Red solid, blue dashed, green dotted, brown dot-dashed, and black thin solid lines correspond to $\mu = 10$ meV, $\mu = 20$ meV, $\mu = 30$ meV, $\mu = 40$ meV, and $\mu = 50$ meV, respectively. The left panel is plotted for $\mu = 5$ meV, $\mu = 0$, while the right one represents results obtained for $\mu = 5$, $\mu = 0$. We set $b_{\parallel} = 0.5 b^*$, $T = 0$, and $B_0 = 0$.

IV. EFFECTS OF MULTIPLE PAIRS OF WEYL NODES

In order to study how the presence of several pairs of Weyl nodes affects the physical properties of pseudomagnetic helicons, in this section we consider simple models of Weyl materials with two and three pairs of Weyl nodes, as well as a model of Dirac material with two Dirac points. Formally, the presence of several pairs of Weyl nodes could be taken into account by adding the pair index $\xi$ to the one-particle distribution functions, i.e., $f_{\lambda} \rightarrow f_{\lambda}^{(\xi)}$. Note that, in general, the pairs of Weyl nodes are characterized by different values of the chiral shift $b^{(\xi)}$ and the energy separation $b^{(\xi)}_{0.5}$. By taking this into account and adding the partial contributions due to each pair of Weyl nodes, it is straightforward to derive the expression for the polarization vector. The final result will have the same form as in Eq. (23), but will include an additional sum over the pair index $\xi$.

While the case of a purely magnetic field could be straightforwardly analyzed by using the results in the previous sections without qualitative changes, the case of a strained Weyl material is different. Indeed, contrary to the usual magnetic field, the pseudomagnetic one is connected with the chiral shift $b^{(\xi)}$ and consequently depends on the pair index. In view of different orientations of $b^{(\xi)}$, in general, quasiparticles of the corresponding pairs experience pseudomagnetic fields of different directions and amplitudes. This makes the analysis of strained multipair Weyl or Dirac materials somewhat more complicated.

Let us begin our study with the general expression for the axial vector potential of an arbitrary pair of Weyl nodes.
in a strained material, i.e.,

\[
(A_i^5)_{(\xi)} = -\frac{c}{v_F} \left\{ \sum_{j=1}^{3} (u_{ij} - \delta_{ij} u_{jj}) b_j^{(\xi)} + \frac{b^2 c_i}{\epsilon^2} b_{ij}^{(\xi)} u_{ji} \right\}
\]

where \(u\) is a displacement vector, \(u_{ij} \equiv (\partial_i u_j + \partial_j u_i)/2\) is a strain tensor, and \(c_i\) is a lattice constant in \(i\) direction. The corresponding pseudomagnetic field equals

\[
(B_i^{(\xi)})_{(\xi)} = -\frac{c}{v_F} \left\{ \frac{1}{2} \sum_{j,k,l=1}^{3} \epsilon_{ijk} (\partial_j u_k - 2\delta_{k(i} \partial_j u_{l)}) b_j^{(\xi)} + \sum_{j,k=1}^{3} \frac{b^2 c_i}{\epsilon^2} \delta_{ij} \partial_k u_k b_k^{(\xi)} \right\}.
\]

The amplitude and the direction of this field strongly depend on the directions of the chiral shifts, as well as on the type of strain. Therefore, in the following subsections we will consider three simplified cases: (i) static torsion along the \(+z\) axis in a Weyl material, (ii) static bending along the \(+y\) axis in a Weyl material, and (iii) static torsion along the \(+z\) axis in a Dirac material. For the sake of simplicity, we assume that an external magnetic field is absent.

### A. Weyl materials with torsion

The static torsion along the \(+z\) axis is characterized by the following displacement vector:

\[
u = u_0 z \hat{r} \times \hat{z},
\]

where \(u_0\) is a constant which depends on the magnitude of a torsion and sample details. Let us begin with the simplest model of a Weyl material with two pairs of Weyl nodes. The first pair is characterized by the chiral shift \(b^{(1)} = (0, 0, b_z)\). Further, we assume that the chiral shift \(b^{(2)} = (b_x, 0, 0)\) of the second pair is orthogonal to \(b^{(1)}\) because the case of parallel \(b^{(1)}\) and \(b^{(2)}\) is rather trivial.

Using Eq. (49), one can easily find the following pseudomagnetic fields for the quasiparticles in the vicinity of the first and second pairs of Weyl nodes:

\[
B^{(1)}_{0.5} = \frac{c u_0 b_x}{v_F} \hat{z} \equiv B_{0.5} \hat{z},
\]

\[
B^{(2)}_{0.5} = -\frac{B_{0.5} b_x}{2b_z} \hat{x},
\]

respectively. It is worth noting that the quasiparticles of the second pair of Weyl nodes experience the pseudomagnetic field directed opposite to the chiral shift \(b^{(2)}\). Their contribution to the polarization vector reads

\[
4\pi \mathbf{P}^{(2)} = A^{(2)}_1 (\mathbf{E} \times \hat{x}) + A^{(2)}_2 (\hat{k} \times \mathbf{E}) + A^{(2)}_3 (\mathbf{b}^{(2)} \times \mathbf{E}) + A^{(2)}_4 (\mathbf{E} - \hat{x}(\mathbf{E} \cdot \hat{x})) + A^{(2)}_5 \hat{x}(\mathbf{E} \cdot \hat{x}).
\]

Here coefficients \(A^{(\xi)}_j\) with \(j = 1, 5\) and \(\xi = 1, 2\) are given by Eqs. (26) through (30) with \(\mu \rightarrow \mu^{(\xi)}_\lambda = \mu + \lambda \mu^{(\xi)}_5\), \(b_0 \rightarrow b^{(\xi)}_{0}\), and \(B_{0,\lambda} \rightarrow B^{(\xi)}_{0,\lambda} = \lambda B^{(\xi)}_{0,5}\). Then, we easily find the total dielectric tensor in the model under consideration:

\[
\varepsilon^{ml} = \delta^{ml} n_0^2 + 4\pi \left( \chi^{(1)} \right)^{ml} + 4\pi \left( \chi^{(2)} \right)^{ml} = \delta^{ml} n_0^2 + A^{(2)}_1 \epsilon^{ml1} + A^{(2)}_1 \epsilon^{ml1} + \left( A^{(1)}_2 + A^{(2)}_2 \right) \epsilon^{ml1} + A^{(1)}_3 \left( \delta^{ml} - \delta^{ml1} \delta^{1l} \right) + A^{(2)}_3 (\delta^{ml} + \delta^{ml1} \delta^{1l} - \delta^{ml1} \delta^{1l} + A^{(1)}_5 \delta^{ml3} \delta^{1l} + A^{(2)}_5 \delta^{ml2} \delta^{1l}.
\]

By solving the characteristic equation \(1\) with the dielectric tensor \(54\), we find that there are gapless collective excitations in the strained Weyl material with two pairs of Weyl nodes whose frequency dependence on the wave vector for different values of \(b_z\) is plotted in Fig. 4. As one can see, the frequency of the gapless mode in the long-wavelength limit depends linearly on the wave vector even in equilibrium, i.e., at \(\mu^{(1)}_5 = -\epsilon b^{(1)}_0\) and \(\mu^{(2)}_5 = -\epsilon b^{(2)}_0\). The corresponding dependence can be approximated as

\[
\omega \simeq v_1 |k| + O(k^3),
\]
where

\[ v_1 = \tilde{A}_5^{(1)} \left[ c^2 \tilde{A}_5^{(2)} + (\tilde{A}_1^{(1)} + \tilde{A}_1^{(2)})^2 \right] \left\{ \tilde{A}_5^{(1)} (\tilde{A}_1^{(1)} + \tilde{A}_1^{(2)}) (\tilde{A}_1^{(1)} - b_z \tilde{A}_3) + \sqrt{\tilde{A}_5^{(1)}} \left[ \tilde{A}_5^{(1)} (\tilde{A}_2^{(1)} + \tilde{A}_2^{(2)})^2 (\tilde{A}_1^{(1)} - b_z \tilde{A}_3)^2 \right] \right\}^{-1} \]

\[ + \left( c^2 \tilde{A}_5^{(2)} + (\tilde{A}_2^{(1)} + \tilde{A}_2^{(2)})^2 \right) \left( \tilde{A}_5^{(1)} \tilde{A}_5^{(2)} (n_0^2 + \tilde{A}_4^{(1)} + \tilde{A}_4^{(2)}) - \tilde{A}_5^{(1)} (\tilde{A}_1^{(1)} - b_z \tilde{A}_3)^2 - \tilde{A}_5^{(2)} (\tilde{A}_1^{(2)} - b_z \tilde{A}_3)^2 \right)^{1/2} \]

This result shows that the presence of the second pair of Weyl nodes does affect the physical properties of pseudomagnetic helicons in a nontrivial way, namely, the quadratic dependence of the frequency on the wave vector is replaced by a linear one.

The effect becomes even more dramatic when another pair of Weyl nodes (with a chiral shift perpendicular to the other two) is added to the model. To see this, let us assume that there are three pairs of Weyl nodes with the chiral shifts orthogonal to each other, i.e., \( b^{(1)} = (0, 0, b_z), b^{(2)} = (b_x, 0, 0), \) and \( b^{(3)} = (0, b_y, 0). \) Under the same torsion, the pseudomagnetic field for the quasiparticles in the vicinity of the third pair of Weyl nodes is

\[ B_{0.5}^{(3)} = -\frac{B_{0.5} b_y}{2b_z} \hat{y}. \]

The corresponding contribution to the polarization vector reads

\[ 4\pi \mathbf{P}^{(3)} = A_1^{(3)} (\mathbf{E} \times \hat{y}) + A_2^{(3)} (\hat{k} \times \mathbf{E}) + A_3(b^{(3)} \times \mathbf{E}) + A_4^{(3)} (\mathbf{E} - \hat{y}(\mathbf{E} \cdot \hat{y})) + A_5^{(3)} \hat{y}(\mathbf{E} \cdot \hat{y}). \]

By taking into account the contributions from all three pairs of Weyl nodes in the characteristic equation, we find that the corresponding collective mode becomes gapped. In other words, there is no gapless helicon in the spectrum. The case of a Weyl material with more than three pairs of nodes can be straightforwardly analyzed by using the results obtained here.

**B. Weyl materials with bending**

Let us briefly discuss the case where a pseudomagnetic field is induced by bending the film of a Weyl material with three pairs of mutually orthogonal Weyl nodes: \( b^{(1)} = (0, 0, b_z), b^{(2)} = (b_x, 0, 0), \) and \( b^{(3)} = (0, b_y, 0). \) By using the model of Ref. \[24\], we assume that the bending along the +\( y \) axis can be described by the following displacement vector:

\[ \mathbf{u} = u_1 \hat{x} + \hat{z}, \]
where \( u_1 \) is a constant which depends on the magnitude of banding and sample properties. From the general result in Eq. (49), we find the following pseudomagnetic fields for all three Weyl nodes:

\[
B_{0,5}^{(1)} = cu_1 \left( \frac{v_F^2}{c^2} + \frac{b_z}{2v_F} \right) \hat{y} \equiv \tilde{B}_{0,5} \hat{y}, \quad (60)
\]

\[
B_{0,5}^{(2)} = B_{0,5}^{(3)} = 0. \quad (61)
\]

Note that a nonzero pseudomagnetic field is produced only for the pair with \( b \parallel \hat{z} \), and its direction is orthogonal to the chiral shift. This is qualitatively different from the case of torsion discussed in the previous subsection, where the pseudomagnetic fields were either along or against the directions of the chiral shifts, see Eqs. (51), (52), and (57). In the case of bending, on the other hand, the two pairs with the chiral shifts orthogonal to the \( +z \) axis do not experience any pseudomagnetic field at all.

Thus, in the model at hand, the polarization vector for the first pair is given by Eq. (58) with the replacement \( A_j^{(3)} \rightarrow A_j^{(1)} (j = 1, 5), b_3^{(3)} \rightarrow b_1^{(1)}, \mu_j^{(3)} \rightarrow \mu_j^{(1)} = \mu + \lambda \mu_5^{(1)} \), and \( B_{0,\lambda}^{(3)} \rightarrow B_{0,\lambda}^{(1)} = \lambda \tilde{B}_{0,5} \). By making use of the results from our previous study \cite{27}, we find that coefficients (26) through (30) for the second and third pairs in the long-wavelength limit equal

\[
A_1^{(\xi)} = 0, \quad (62)
\]

\[
A_2^{(\xi)} = \frac{2k e^2 (3e b_0^{(\xi)} + 2 \mu_5^{(\xi)})}{3 \pi \omega^2 \hbar^2} \equiv \frac{k \tilde{A}_2^{(\xi)}}{\omega^2}, \quad (63)
\]

\[
A_3^{(\xi)} = A_3^{(1)} = A_3, \quad (64)
\]

\[
A_4^{(\xi)} = -\frac{4e^2}{3\pi \hbar^2 v_F \omega^2} \left( \mu_5^{(\xi)} + \frac{\mu_5^{(1)}}{3} \right) \equiv \frac{\tilde{A}_4^{(\xi)}}{\omega^2}, \quad (65)
\]

\[
A_5^{(\xi)} = A_5^{(1)}, \quad \tilde{A}_5^{(\xi)} = \tilde{A}_4^{(\xi)}, \quad (66)
\]

where \( \xi = 2, 3 \). Note that while \( A_1^{(\xi)} = 0 \), the coefficients \( A_4^{(\xi)} \) for the second and third pairs depend on frequency. This has a profound effect on the properties of collective modes, i.e., they become gapped. There are three solutions to Eq. (4). One of them describes a longitudinal mode with the gap of the order of the Langmuir frequency. The other two are

\[
\omega_{\pm} \simeq \sqrt{(A_{1,1} - A_{3,1}) b_0^y - 4 A_{1,2} (n_0^2 + A_{4,0}) \mp \frac{A_{1,1} - A_{3,1} b_0^x}{2(n_0^2 + A_{4,0})} \pm \frac{A_{2,2}}{[(A_{1,1} - A_{3,1} b_0^y)^2 - 4 A_{1,2} (n_0^2 + A_{4,0})]^{1/2}}}
\]

\[
+ k^2 C_2 \left( [(A_{1,1} - A_{3,1} b_0^y)^2 - 4 A_{1,2} (n_0^2 + A_{4,0})] - A_{2,2} (n_0^2 + A_{4,0}) \right) \left( [(A_{1,1} - A_{3,1} b_0^y)^2 - 4 A_{1,2} (n_0^2 + A_{4,0})]^{3/2} + O(k^3). \right) \quad (67)
\]

Here, for simplicity, we ignored the small corrections proportional to \( b_x \) and \( b_y \), and introduced the following notation:

\[
A_{1,1} = \sum_{\xi=1}^3 \tilde{A}_1^{(\xi)}, \quad (68)
\]

\[
A_{2,2} = \sum_{\xi=1}^3 \tilde{A}_2^{(\xi)}, \quad (69)
\]

\[
A_{3,1} = 3 A_3, \quad (70)
\]

\[
A_{4,0} = A_4^{(1)}, \quad (71)
\]

\[
A_{4,2} = \tilde{A}_4^{(2)} + \tilde{A}_4^{(3)}, \quad (72)
\]

\[
A_{5,2} = \sum_{\xi=1}^3 \tilde{A}_5^{(\xi)}. \quad (73)
\]

By analyzing Eq. (67), we find that the transverse modes are also gapped and their energies are reminiscent of the transverse plasma frequencies \( \omega_{\pm}^{(\xi)} \) of the chiral pseudomagnetic plasmons \cite{27}.

In conclusion, the physical properties of pseudomagnetic helicons in a multipair Weyl material are qualitatively different from those with a single pair of Weyl nodes. They are unlike the magnetic helicons, for which the multipair case is a trivial generalization of a single pair one.
C. Dirac materials

Let us consider the pseudomagnetic helicons in the experimentally relevant model of the Dirac material with two Dirac points, e.g., for A$_3$Bi (where A=Na,K,Rb). In view of the $\mathbb{Z}_2$ structure of such a model [43], it can be viewed as a superposition of two pairs of Weyl nodes with opposite chiral shifts: $\mathbf{b}^{(1)} = (0,0,b_2)$ and $\mathbf{b}^{(2)} = (0,0,-b_2)$. Then, as follows from the analysis in Secs. IV A and IV B, strains produce equal in magnitude but opposite in direction pseudomagnetic fields for each pair of the Weyl nodes. The polarization vector for the first pair is given by

$$\mathbf{b}^{(1)} = (0,0,b_2)$$

and for the second pair

$$\mathbf{b}^{(2)} = (0,0,-b_2).$$

The necessary ingredients for the existence of these helicons are gapless helicon-type modes in strained Weyl materials. Unlike the usual helicons, these collective excitations exist even in the absence of a background magnetic field. The necessary ingredients for the existence of these helicons are a strain-induced pseudomagnetic field $\mathbf{B}_{0,5}$ and a chiral chemical potential $\mu_5$. The latter appears naturally in the equilibrium state of a parity-odd Weyl material with a nonzero energy separation $b_0$ between the Weyl nodes. We call this type of collective excitation a pseudomagnetic helicon.

V. SUMMARY AND DISCUSSIONS

By making use of the consistent chiral kinetic theory, we obtained and analyzed the spectrum of the low-energy gapless helicon-type modes in strained Weyl materials. Unlike the usual helicons, these collective excitations exist even in the absence of a background magnetic field. The necessary ingredients for the existence of these helicons are a strain-induced pseudomagnetic field $\mathbf{B}_{0,5}$ and a chiral chemical potential $\mu_5$. Note that the latter appears naturally in the equilibrium state of a parity-odd Weyl material with a nonzero energy separation $b_0$ between the Weyl nodes. We call this type of collective excitation a pseudomagnetic helicon.
We found that in the equilibrium state with $\mu_5 = -eb_0$, when both $B_{0.5}$ and $\mu_5$ are present, the pseudomagnetic helicon has a conventional, quadratic dependence of its frequency on the wave vector $k$. The situation changes qualitatively in the case $B_{0.5} \neq 0$ ($B_0 \neq 0$) but $\mu_5 = 0$ ($\mu = 0$), where the dispersion becomes approximately linear in $k$. We suggest also that linear dispersion relations for helicons are possible in the out-of-equilibrium states of Weyl materials with $eb_0 + \mu_5 \neq 0$. The corresponding (steady) states of matter could be induced, for example, by applying external electromagnetic fields with $E_0 \cdot B_0 \neq 0$. In this paper, we also studied the effects of temperature, as well as electric and chiral chemical potentials on the properties of helicons. We found, in particular, that all three of them have a tendency to decrease the helicon frequency for a given wave vector.

It is worth noting that the necessary ingredients for the existence of pseudomagnetic helicons are naturally present in Weyl materials, making them ideal platforms to study the anomalous physics. Indeed, the pseudomagnetic field $B_{0.5}$ can be induced by a strain and the chiral chemical potential $\mu_5$ in equilibrium is determined by the energy separation between Weyl nodes. The effect of the chiral shift $b$ on the pseudomagnetic helicon is weak, but may be detectable via the change of its frequency.

Further, we showed that the gapless collective modes can exist also in Weyl materials with many pairs of Weyl nodes, as well as in some Dirac materials. For the simplest model of a multipair Weyl material with two pairs of Weyl nodes under the static torsion, we found that the frequency of these modes is linear in the wave vector even in equilibrium. This result is clearly different from the usual, quadratic in $k$, dispersion law of the magnetic helicons in Weyl materials with many pairs of nodes or their pseudomagnetic counterparts for a single pair of Weyl nodes. Moreover, for a Weyl material with three pairs of Weyl nodes and mutually orthogonal chiral shifts, gapless modes are absent. The pseudomagnetic helicons are also absent when strains do not produce pseudomagnetic field for a certain pair of Weyl nodes. Moreover, we investigated the case of Dirac materials with two Dirac points. Owing to the nontrivial $Z_2$ structure, the pseudomagnetic helicons can propagate in these materials. The dispersion law of such helicons ranges from quadratic in $k$ when the Dirac points are separated in energy to linear when such a separation is absent. The case of a general Weyl matter with many pairs of Weyl nodes in the presence of pseudomagnetic as well as background magnetic fields deserves a further in-depth investigation. While such an analysis could be done, in principle, by using the results of the present study, it is rather cumbersome and will be reported elsewhere.

Last but not least, we would like to propose a simple experimental setup that should allow one to detect pseudomagnetic helicons. Based on the same idea that is used in metals, it requires measuring the amplitude of transmission of an electromagnetic wave through a Weyl or Dirac crystal as a function of an applied strain (which can be quantified by a bending or torsion angle), or as a function of the frequency at a fixed strain. Because of an interference of standing helicon waves inside the sample, the resulting signal should oscillate as the function of strain, after the strain reaches a sufficiently large magnitude. Note that overcoming a critical value of the strain corresponds to entering the regime of a sufficiently large pseudocyclotron frequency compared to the value of the pseudomagnetic helicon frequency. Indeed, this is the condition for the existence of pseudomagnetic helicons that can propagate without suffering too much damping. In such a setup, it is also possible to study the effects of the chiral shift parameter by changing the orientation of the crystal and/or by applying strains along different directions.

Appendix A: Equations of the consistent chiral kinetic theory

In this appendix, we briefly review the main aspects of the consistent chiral kinetic theory considered in Refs. [26, 27]. The time evolution of one-particle distribution functions $f_\lambda(t, \mathbf{p}, \mathbf{r})$ for the fermions of chirality $\lambda = \pm$ are governed in the chiral kinetic theory [32, 33] by the following equation in the collisionless limit:

$$\partial_t f_\lambda + \frac{1}{1 + \frac{e}{c}(\mathbf{B}_\lambda \cdot \Omega_\lambda)} \left[ (e \tilde{E}_\lambda + \frac{e}{c}(\mathbf{v} \times \mathbf{B}_\lambda) + \frac{e^2}{c}(\tilde{E}_\lambda \cdot \mathbf{B}_\lambda)\Omega_\lambda) \cdot \partial_\mathbf{p} f_\lambda + (\mathbf{v} + e(\tilde{E}_\lambda \times \Omega_\lambda) + \frac{e}{c}(\mathbf{v} \cdot \Omega_\lambda)\mathbf{B}_\lambda) \cdot \partial_\mathbf{r} f_\lambda \right] = 0,$$

where $\Omega_\lambda = \lambda \hbar \mathbf{p}/(2|\mathbf{p}|^3)$ is the Berry curvature [42], $\tilde{E}_\lambda = E_\lambda - (1/e)\partial_\mathbf{r} f_\lambda$, the factor $1/[1 + e(\mathbf{B}_\lambda \cdot \Omega_\lambda)/c]$ accounts for the correct definition of the phase-space volume that satisfies Liouville’s theorem [44, 45], and we introduced the
following effective electric and magnetic fields for fermions of a given chirality:

\[ \mathbf{E}_\lambda = \mathbf{E} + \lambda \mathbf{E}_5, \quad \mathbf{B}_\lambda = \mathbf{B} + \lambda \mathbf{B}_5. \]  

(A2)

In Weyl materials, the pseudoelectric field \( \mathbf{E}_5 \) can be generated by dynamical deformations of the sample and the pseudomagnetic field \( \mathbf{B}_5 \) can be induced by a static torsion or bending \( [20, 23, 24] \). The fermion energy \( \epsilon_\mathbf{p} \) in the presence of a weak effective magnetic field \( \mathbf{B}_\lambda, \hbar |e \mathbf{B}_\lambda|/(cp^2) \ll 1 \), is given by \([40]\)

\[ \epsilon_\mathbf{p} = v_F \mathbf{p} \left[ 1 - \frac{e}{c} (\mathbf{B}_\lambda \cdot \Omega_\lambda) \right], \]  

(A3)

where \( v_F \) is the Fermi velocity, \( \rho \equiv |\mathbf{p}|, e \) is an electric charge (\( e < 0 \) for the electron), \( c \) is the speed of light, and \( \mathbf{p}/\rho = \mathbf{p}/p \). The quasiparticle velocity is defined as follows:

\[ \mathbf{v} = \partial_\mathbf{p} \epsilon_\mathbf{p} = v_F \mathbf{p} \left[ 1 + 2 \frac{e}{c} (\mathbf{B}_\lambda \cdot \Omega_\lambda) \right] - \frac{e v_F}{c} \mathbf{B}_\lambda (\mathbf{p} \cdot \Omega_\lambda). \]  

(A4)

In equilibrium, the function \( f_\lambda \) is given by the Fermi-Dirac distribution

\[ f_\lambda^{(eq)} = \frac{1}{e^{(\mu_\lambda - \mu_\lambda^0)/T} + 1}, \]  

(A5)

where \( \mu_\lambda = \mu + \lambda \mu_5 \) denotes the effective chemical potential for the left- (\( \lambda = - \)) and right-handed (\( \lambda = + \)) fermions, \( \mu \) is the electric chemical potential, \( \mu_5 \) is the chiral chemical potential, and \( T \) is temperature. The equilibrium distribution function for holes (antiparticles) \( f_\lambda^{(eq)} \) is obtained by replacing \( \mu \rightarrow -\mu_\lambda \). In addition, in the chiral kinetic equation for the hole distribution function, one should change the sign of the electric charge and the Berry curvature \( \Omega_\lambda \rightarrow -\Omega_\lambda \).

By definition, the electric current density consists of the left- and right-handed fermion contributions, i.e., \( \rho = \sum_{\lambda = \pm} \rho_\lambda \), where

\[ \rho_\lambda = \sum_{\mathbf{p}, \lambda} e \int \frac{d^3 \mathbf{p}}{(2\pi \hbar)^3} \left[ 1 + \frac{e}{c} (\mathbf{B}_\lambda \cdot \Omega_\lambda) \right] f_\lambda. \]  

(A6)

The current densities of the left- and right-handed fermions are \([33, 40]\)

\[ \mathbf{j}_\lambda = \sum_{\mathbf{p}, \lambda} e \int \frac{d^3 \mathbf{p}}{(2\pi \hbar)^3} \left[ \mathbf{v} + \frac{e}{c} \epsilon_\mathbf{p} \mathbf{B}_\lambda (\partial_\mathbf{p} \cdot \Omega_\lambda) + \frac{e}{c} (\mathbf{v} \cdot \Omega_\lambda) \mathbf{B}_\lambda + e (\mathbf{E}_\lambda \times \Omega_\lambda) \right] f_\lambda + \sum_{\mathbf{p}, \lambda} e \partial_\mathbf{r} \times \int \frac{d^3 \mathbf{p}}{(2\pi \hbar)^3} f_\lambda \epsilon_\mathbf{p} \Omega_\lambda. \]  

(A7)

where \( \sum_{\mathbf{p}, \lambda} \) denotes the summation over particles and antiparticles (holes). Therefore, the electric current density is given by \( \mathbf{j} = \sum_{\lambda = \pm} \mathbf{j}_\lambda \). Note that the last term in Eq. (A7) is the magnetization current.

By using Eqs. (A6) and (A7) together with the Maxwell equations, one finds that the chiral and electric currents satisfy the following continuity equations:

\[ \partial_t \rho_\lambda + \partial_\mathbf{r} \cdot \mathbf{j}_\lambda = \frac{e^3}{2\pi^2 \hbar^2 c} \left[ (\mathbf{E} \cdot \mathbf{B}) + (\mathbf{E}_5 \cdot \mathbf{B}_5) \right]; \]  

(A8)

\[ \partial_t \rho + \partial_\mathbf{r} \cdot \mathbf{j} = \frac{e^3}{2\pi^2 \hbar^2 c} \left[ (\mathbf{E} \cdot \mathbf{B}_5) + (\mathbf{E}_5 \cdot \mathbf{B}_5) \right]. \]  

(A9)

The first equation describes the anomalous chiral charge nonconservation \([17]\) and can be understood as a pumping of the chiral charge between the Weyl nodes of opposite chiralities. The second equation, naively, describes the anomalous local nonconservation of the electric charge when both electromagnetic and pseudoelectromagnetic fields are present. As emphasized in Refs. \([26, 27]\), the conservation of the electric charge in the chiral kinetic theory must be enforced locally by using the consistent definition of the electric current \([34, 53, 48]\):

\[ J^\nu \equiv (cp + c\delta \rho, \mathbf{j} + \delta \mathbf{j}), \]  

(A10)

where

\[ \delta j^\mu = \frac{e^3}{4\pi^2 \hbar^2 c} \epsilon^{\mu \nu \rho \lambda} A^5_{\nu} F_{\rho \lambda}. \]  

(A11)

and \( A^5_{\nu} = b_{\nu} + \tilde{A}^5_{\nu} \) is the axial potential, which is an observable quantity. Indeed, while \( b_0 \) and \( b \) correspond to energy and momentum-space separations of the Weyl nodes, respectively, \( A^5_{\nu} \) describes strain-induced axial or, equivalently,
pseudoelectromagnetic field directly related to the deformation tensor \([13] [24]\). From a physics viewpoint, the additional contributions to electric current \([\text{A11}]\) capture the local changes of \(\rho\) and \(\mathbf{j}\) associated with the deformations of the crystal lattice that cannot be captured in other ways by the chiral kinetic theory of low-energy quasiparticles.

As is easy to check, the consistent electric current is nonanomalous, \(\partial_\nu J^\nu = 0\), and, therefore, the electric charge is locally conserved. It is useful to rewrite the topological contribution \([\text{A11}]\) explicitly in components

\[
\delta \rho = \frac{e^3}{2\pi^2 \hbar^2 c^2} (\mathbf{b} \cdot \mathbf{B}), \\
\delta \mathbf{j} = \frac{e^3}{2\pi^2 \hbar^2 c} b_0 \mathbf{B} - \frac{e^3}{2\pi^2 \hbar^2 c} (\mathbf{b} \times \mathbf{E}),
\]

where we assumed that the field \(\mathbf{B}_5\) is weak or, in other words, that \(\tilde{A}_5\) is negligible compared to the chiral shift \(\mathbf{b}\).

The first term in \(\delta \mathbf{j}\) at \(b_0 = -\mu_5/e\) leads to the cancellation of the CME current in the equilibrium state \([35] [32]\) as is required for solids \([30] [38]\). The second term in Eq. \([\text{A13}]\) describes the anomalous Hall effect in Weyl materials \([30] [38]\) in the framework of the semiclassical kinetic theory \([26]\).

**Appendix B: Coefficients \(g_n\)**

In this appendix, we present the explicit results for the Fourier coefficients \(g_n\) defined by Eq. \([19]\). The integral representation for the Fourier coefficients is given by

\[
g_n = -\frac{i}{2\pi(a_1 + n)} \int_0^{2\pi} d\tau e^{i\tau_2 \sin \tau - i\tau_2} \left\{ a_4 - \frac{a_5}{2p^2} E_{k} k_{\parallel} k_{\perp} p_{\perp} \sin \phi_E \right. \\
+ e^{i\phi} \left[ \frac{a_3}{2} e^{-i\phi_E} + \frac{a_5}{2p^2} E_{k} k_{\parallel} k_{\perp} p_{\parallel} \sin \phi_E + i \frac{a_5}{2p^2} E_{k} k_{\parallel} k_{\perp} p_{\perp} + \frac{a_5}{2p^2} E_{k} k_{\parallel} k_{\perp} p_{\parallel} e^{-i\phi_E} \right] \\
+ e^{-i\phi} \left[ \frac{a_3}{2} e^{i\phi_E} + \frac{a_5}{2p^2} E_{k} k_{\parallel} k_{\perp} p_{\parallel} \sin \phi_E - i \frac{a_5}{2p^2} E_{k} k_{\parallel} k_{\perp} p_{\perp} + \frac{a_5}{2p^2} E_{k} k_{\parallel} k_{\perp} p_{\parallel} e^{i\phi_E} \right] \\
+ i e^{-2i\phi} \frac{a_5 p^2}{4p^2} \left[ E_{k} k_{\perp} - e^{-i\phi_E} E_{k} k_{\perp} \right] \\
- i e^{-2i\phi} \frac{a_5 p^2}{4p^2} \left[ E_{k} k_{\perp} - e^{i\phi_E} E_{k} k_{\perp} \right] \left\} \right. \}
\]

where coefficients \(a_i\) with \(i = 1, 5\) are given by Eq. \([14]\). After performing the integration over \(\tau\), we derive

\[
g_n = -\frac{i}{a_1 + n} \left\{ J_n(a_2) \left[ a_4 - \frac{a_5}{2p^2} E_{k} k_{\parallel} k_{\perp} p_{\perp} \sin \phi_E \right] \\
+ J_{n-1}(a_2) \left[ \frac{a_3}{2} e^{-i\phi_E} + \frac{a_5}{2p^2} E_{k} k_{\parallel} k_{\perp} p_{\parallel} \sin \phi_E + i \frac{a_5}{2p^2} E_{k} k_{\parallel} k_{\perp} p_{\perp} + \frac{a_5}{2p^2} E_{k} k_{\parallel} k_{\perp} p_{\parallel} e^{-i\phi_E} \right] \\
+ J_{n+1}(a_2) \left[ \frac{a_3}{2} e^{i\phi_E} + \frac{a_5}{2p^2} E_{k} k_{\parallel} k_{\perp} p_{\parallel} \sin \phi_E - i \frac{a_5}{2p^2} E_{k} k_{\parallel} k_{\perp} p_{\perp} + \frac{a_5}{2p^2} E_{k} k_{\parallel} k_{\perp} p_{\parallel} e^{i\phi_E} \right] \\
+ i J_{n-2}(a_2) \left[ \frac{a_5 p^2}{4p^2} \left[ E_{k} k_{\perp} - e^{-i\phi_E} E_{k} k_{\perp} \right] - i J_{n+2}(a_2) \frac{a_5 p^2}{4p^2} \left[ E_{k} k_{\perp} - e^{i\phi_E} E_{k} k_{\perp} \right] \right\} \right. \}
\]

Here we used the table integral

\[
J_n(x) = \frac{1}{2\pi} \int_0^{2\pi} e^{i(n\theta - x \sin \theta)} d\theta,
\]

and the following identities for the Bessel functions: \(J_{-n}(x) = (-1)^n J_n(x)\) and \(J_n(-x) = (-1)^n J_n(x)\) (see formulas 8.411.1 and 8.404.2 in Ref. \([49]\)).
Appendix C: Polarization vector

In this appendix, we present the details of calculation of the polarization vector \( \mathbf{P} \) in the limit of small \( \omega \). The polarization vector \[^{19}\] at \( n = 0, \pm 1 \) reads as

\[
\mathbf{P} \simeq \sum_{\lambda = \pm} \sum_{p, a \neq 1} \frac{i e}{\omega} \int \frac{d^3 p}{(2\pi h)^3} \left[ e(\mathbf{E} \times \Omega_\lambda) + \frac{e}{\omega} (\mathbf{v} \cdot \Omega_\lambda) (\mathbf{k} \times \mathbf{E}) + \frac{e}{c} (\delta \mathbf{v} \cdot \Omega_\lambda) \mathbf{B}_{0, \lambda} \right] f_{\lambda}^{(eq)} + \sum_{\lambda = \pm} \frac{\lambda e^2 h v_F}{2\omega^2} \int \frac{d^3 p}{(2\pi h)^3} \frac{1}{p} f_{\lambda}^{(eq)} [\mathbf{k} \times \Omega_\lambda] (\tilde{p} \cdot [\mathbf{k} \times \mathbf{E}]) - i \frac{e^3}{2\pi^2 \omega c h^2} (\mathbf{b} \times \mathbf{E}) + i \frac{e^3 b_0}{2\pi^2 \omega^2 h^2} (\mathbf{k} \times \mathbf{E}) + \sum_{\lambda = \pm} \sum_{n = -1}^{1} \sum_{p, a \neq 1} i e \omega \int \frac{d^3 p}{(2\pi h)^3} v_F \tilde{p} \left[ 1 + 2 \frac{e}{c} (\mathbf{B}_{0, \lambda} \cdot \Omega_\lambda) \right] g_n e^{i n \phi} + O(B_{0, \lambda}^2),
\]

(C1)

where we neglected terms of order \( O(B_{0, \lambda}^3) \) and terms suppressed by powers of the wave vector, such as \( k f_{\lambda}^{(l)} \). Also, \( \delta \nu \) is defined in Eq. \[^{24}\]. Using the expansion of the equilibrium distribution function \[^{15}\], the first two terms in Eq. \[^{15}\] can be rewritten in the following form (we dropped the summation over particles and antiparticles):

\[
\mathbf{X}_1^{(a)} = -\frac{e^2}{\omega} \int \frac{d^3 p}{(2\pi h)^3} (\mathbf{E} \times \Omega_\lambda) f_{\lambda}^{(eq)} \simeq -i \frac{e^3 h v_F (\mathbf{E} \times \mathbf{B}_{0, \lambda})}{12c \omega} \int \frac{d^3 p}{(2\pi h)^3} \frac{1}{p^3} \frac{\partial f_{\lambda}^{(0)}}{\partial \tilde{p}} + O(B_{0, \lambda}^2),
\]

(C2)

\[
\mathbf{X}_1^{(b)} = -\frac{e^2}{\omega} \int \frac{d^3 p}{(2\pi h)^3} \frac{\lambda e^2 h v_F}{2\omega^2} (\mathbf{E} \cdot [\mathbf{k} \times \tilde{p}]) (\mathbf{k} \times \Omega_\lambda) f_{\lambda}^{(eq)} \simeq -\frac{e^3 v_F^2}{24\pi^2 h^2 \omega^2} \int \frac{dp}{p} f_{\lambda}^{(0)} [\mathbf{k} \times (\mathbf{k} \times \mathbf{E})] + O(B_{0, \lambda}^2),
\]

(C3)

\[
\mathbf{X}_1^{(c)} = \frac{i e^2}{\omega} \int \frac{d^3 p}{(2\pi h)^3} (\mathbf{v} \cdot \Omega_\lambda) f_{\lambda}^{(eq)} \simeq i (\mathbf{k} \times \mathbf{E}) \frac{\lambda e^2 T}{4\pi^2 h^2 \omega^2} \ln \left( \frac{1 + e^{\mu_\lambda/T}}{1 + e^{-\mu_\lambda/T}} \right) + O(B_{0, \lambda}^2),
\]

(C4)

\[
\mathbf{X}_1^{(d)} = \frac{i e^2}{\omega} \int \frac{d^3 p}{(2\pi h)^3} (\delta \mathbf{v} \cdot \mathbf{B}_{0, \lambda}) \mathbf{k} f_{\lambda}^{(eq)} \simeq i \frac{e^3 h v_F \mathbf{E} \cdot \mathbf{B}_{0, \lambda}}{12c \omega} \int \frac{d^3 p}{(2\pi h)^3} \frac{1}{p^3} \frac{\partial f_{\lambda}^{(0)}}{\partial \tilde{p}} + \frac{i \lambda e^2 v_F}{4\pi^2 h^2 \omega^2} (\mathbf{k} \times \mathbf{E}) + O(B_{0, \lambda}^2),
\]

(C5)

where \( f_{\lambda}^{(0)} = \frac{1}{e^{(\mu_\lambda/T) + 1}} \) is the equilibrium function at \( \mathbf{B}_{0, \lambda} = 0 \) and \( \epsilon_{\mathbf{p}}^{(0)} = v_F p \). By adding the contribution of holes (antiparticles), we obtain

\[
\mathbf{X}_1 = \sum_{p, a} \left( \mathbf{X}_1^{(a)} + \mathbf{X}_1^{(b)} + \mathbf{X}_1^{(c)} + \mathbf{X}_1^{(d)} \right) = -i \frac{e^3 h^2 v_F (\mathbf{E} \times \mathbf{B}_{0, \lambda})}{12c \omega} \int \frac{d^3 p}{(2\pi h)^3} \frac{1}{p^3} \frac{\partial f_{\lambda}^{(0)}}{\partial \tilde{p}} - \frac{\partial \bar{f}_{\lambda}^{(0)}}{\partial \tilde{p}} + \frac{i \lambda e^2 v_F}{4\pi^2 h^2 \omega^2} (\mathbf{k} \times \mathbf{E}) \left[ \ln \left( 1 + e^{\mu_\lambda/T} \right) - \ln \left( 1 + e^{-\mu_\lambda/T} \right) \right]
\]

\[
\left[ \left. -i \frac{e^3 h^2 v_F (\mathbf{E} \times \mathbf{B}_{0, \lambda})}{12c \omega} \int \frac{d^3 p}{(2\pi h)^3} \frac{1}{p^3} \frac{\partial f_{\lambda}^{(0)}}{\partial \tilde{p}} - \frac{\partial \bar{f}_{\lambda}^{(0)}}{\partial \tilde{p}} + \frac{i \lambda e^2 v_F}{4\pi^2 h^2 \omega^2} (\mathbf{k} \times \mathbf{E}) \right| \right. \left. - \frac{\lambda e^2 v_F}{24\pi^2 h^2 \omega^2} F \left( \frac{\mu_\lambda}{T} \right) + \frac{i \lambda e^2 v_F}{4\pi^2 h^2 \omega^2} (\mathbf{k} \times \mathbf{E}) + O(B_{0, \lambda}^2) \right]
\]

(C7)

where the replacements \( e \to -e \), \( \mu_\lambda \to -\mu_\lambda \), and \( \lambda \to -\lambda \) in the Berry curvature \( \Omega_\lambda \) were made for holes (antiparticles). Further, the function

\[
F (\nu_\lambda) \equiv -T \int \frac{dp}{p} \left( \frac{\partial f_{\lambda}^{(0)}}{\partial \tilde{p}} - \frac{\partial \bar{f}_{\lambda}^{(0)}}{\partial \tilde{p}} \right)
\]

(C8)

can be easily computed numerically. Thus, Eq. \[^{15}\] can be rewritten as

\[
\mathbf{P} \simeq \sum_{\lambda = \pm} \frac{e^3 v_F (\mathbf{E} \times \mathbf{B}_{0, \lambda})}{24\pi^2 h \omega c T} F \left( \frac{\mu_\lambda}{T} \right) - i \frac{e^3}{2\pi^2 \omega c h^2} (\mathbf{b} \times \mathbf{E}) + i \frac{e^2 (b_0 + \mu_\lambda)}{2\pi^2 \omega^2 h^2} (\mathbf{k} \times \mathbf{E}) + \sum_{\lambda = \pm} \sum_{n = -1}^{1} \sum_{p, a \neq 1} \frac{\pi e^2 v_F^2}{2\omega} \int_0^\infty \frac{dp}{(2\pi h)^3} \int_1^1 d\cos \theta \bar{p}_{\lambda}^2 \left( 1 + \frac{3 \lambda e^2 v_F}{2 c p^3} \right) (\mathbf{E} - \tilde{z} (\mathbf{E} \cdot \hat{z}) \bar{p}_{\lambda}^2 \left( 1 + \frac{3 \lambda e^2 v_F}{2 c p^3} \right) \frac{\partial f_{\lambda}^{(eq)}}{\partial \tilde{p}} + O(B_{0, \lambda}^2),
\]

(C9)

Let us consider the case of small frequencies \( \omega \ll \Omega_\lambda \|p\|^2 \), where \( \Omega_\lambda \) is given in Eq. \[^{20}\] and \( p^* \sim \sqrt{\mu_\lambda^2 + \mu_\lambda^2 + \pi^2 T^2 / v_F} \) is a characteristic momentum, relevant for helicons. In the zero order in \( \omega / \Omega_\lambda \), the fourth term of the above equation
equals
\[
\sum_{n=\pm} P_n^{(0)} \simeq \sum_{\lambda=\pm} \sum_{n=\pm} \sum_{p,a} \left[ n (E - \hat{z} \cdot \mathbf{E}) - i (\hat{z} \times \mathbf{E}) \right] \frac{e v_{FC}^2}{12 \pi^2 \hbar^3 B_0 \omega} \int_0^{\infty} dp \, \frac{p^3 \partial f^{(0)}_{\lambda}}{\partial \epsilon_p} + O(B_{0,\lambda}^2)
\]
\[
= \sum_{\lambda=\pm} \sum_{n=\pm} \sum_{p,a} \left[ n (E - \hat{z} \cdot \mathbf{E}) - i (\hat{z} \times \mathbf{E}) \right] \frac{e T^3}{2 \pi^2 \hbar^3 B_0 \omega} \operatorname{Li}_3 \left( -e^{\mu_\lambda/T} \right) + O(B_{0,\lambda}^2)
\]
\[
= i \sum_{\lambda=\pm} \left[ \mathbf{E} \times \hat{z} \right] \frac{e c \mu_\lambda}{6 \pi^2 \hbar^3 B_0 \omega} \left( \mu_\lambda^2 + \pi^2 T^2 \right) + O(B_{0,\lambda}^2).
\]

(C10)

To the leading order in small \( \omega/\Omega_c \), we have
\[
\sum_{n=\pm} P_n^{(1)} \simeq - \sum_{\lambda=\pm} \sum_{n=\pm} \sum_{p,a} \left[ (E - \hat{z} \cdot \mathbf{E}) - i n (\hat{z} \times \mathbf{E}) \right] \frac{e^2}{12 \pi^2 \hbar^3 B_0^2} \int_0^{\infty} dp \, \frac{p^4 \partial f^{(0)}_{\lambda}}{\partial \epsilon_p} + O(B_{0,\lambda}^2)
\]
\[
= - \sum_{\lambda=\pm} \sum_{n=\pm} \sum_{p,a} \left[ (E - \hat{z} \cdot \mathbf{E}) - i n (\hat{z} \times \mathbf{E}) \right] \frac{2 e^2 T^4}{\pi^2 \hbar^3 B_0 \omega^4} \operatorname{Li}_4 \left( -e^{\mu_\lambda/T} \right) + O(B_{0,\lambda}^2)
\]
\[
= \sum_{\lambda=\pm} \left[ \mathbf{E} - \hat{z} (\mathbf{E} \cdot \hat{z}) \right] \frac{e^2}{6 \pi^2 \hbar^3 B_0 \omega} \left( \mu_\lambda^4 + 2 \pi^2 T^2 + \frac{7 \pi^4 T^4}{15} \right) + O(B_{0,\lambda}^2).
\]

(C11)

The contribution of \( g_0 \) to the polarization vector is given by the last term in Eq. (C11). Its explicit form reads
\[
P_0 \simeq \mathbf{E} \cdot \hat{z} \sum_{p,a} \int_0^{\infty} dp \, \frac{e^2 v_p^2}{6 \pi^2 h \omega^2} \frac{\partial f^{(0)}_{\lambda}}{\partial \epsilon_p} + O(B_{0,\lambda}^2) = \mathbf{E} \cdot \hat{z} \sum_{p,a} \int_0^{\infty} dp \, \frac{e^2 T^2}{3 \pi^2 h v_p \omega} \operatorname{Li}_2 \left( -e^{\mu_\lambda/T} \right)
\]
\[
+ O(B_{0,\lambda}^2) = -\mathbf{E} \cdot \hat{z} \sum_{\lambda=\pm} \frac{e^2}{6 \pi^2 \hbar^3 v_p \omega^2} \left( \mu_\lambda^4 + \frac{\pi^2 T^2}{3} \right) + O(B_{0,\lambda}^2).
\]

(C12)

In the derivation above, we used the following table integral:
\[
\int \frac{d^3 p}{(2 \pi)^3} p^{n-2} \frac{\partial f^{(0)}_{\lambda}}{\partial \epsilon_p} = \frac{T^n \Gamma(n+1)}{2 \pi^2 v_p^{n+1}} \operatorname{Li}_n \left( -e^{\mu_\lambda/T} \right), \quad n \geq 0,
\]

(C13)

where \( \operatorname{Li}_n(x) \) is the polylogarithm function (see formula 1.1.14 in Ref. [50]) where \( \operatorname{Li}_n(x) \equiv \Gamma(x, n) \). We also used the following identities for the polylogarithm functions:
\[
\operatorname{Li}_2(-e^x) + \operatorname{Li}_2(-e^{-x}) = -\frac{x^2}{2} - \frac{\pi^2}{6},
\]
\[
\operatorname{Li}_3(-e^x) - \operatorname{Li}_3(-e^{-x}) = -\frac{x^3}{6} - \frac{\pi^2 x}{6},
\]
\[
\operatorname{Li}_4(-e^x) + \operatorname{Li}_4(-e^{-x}) = -\frac{x^4}{24} - \frac{\pi^2 x^2}{12} - \frac{7 \pi^4}{360}.
\]
