On the capacity functional of the infinite cluster of a
Boolean model

Günter Last∗ Mathew D. Penrose† Sergei Zuyev‡

June 26, 2024

Abstract

The original 2017 version of this paper [Last et al. (2017)] contains a major gap in the proofs. In the subsequent publication [Last et al. (2024)] we indicated how to fix this. For convenience of the reader, we here update the original paper to incorporate the suggested fix.

Consider a Boolean model in \( \mathbb{R}^d \) with balls of random, bounded radii with distribution \( F_0 \), centered at the points of a Poisson process of intensity \( t > 0 \). The capacity functional of the infinite cluster \( Z_\infty \) is given by \( \theta_L(t) = \mathbb{P}\{Z_\infty \cap L \neq \emptyset\} \), defined for each compact \( L \subset \mathbb{R}^d \).

We prove for any fixed \( L \) and \( F_0 \) that \( \theta_L(t) \) is infinitely differentiable in \( t \), except at the critical value \( t_c \); we give a Margulis-Russo type formula for the derivatives. More generally, allowing the distribution \( F_0 \) to vary and viewing \( \theta_L \) as a function of the measure \( F := tF_0 \), we show that it is infinitely differentiable in all directions with respect to the measure \( F \) in the supercritical region of the cone of positive measures on a bounded interval.

We also prove that \( \theta_L(\cdot) \) grows at least linearly at the critical value. This implies that the critical exponent known as \( \beta \) is at most 1 (if it exists) for this model. Along the way, we extend a result of H. Tanemura (1993), on regularity of the supercritical Boolean model in \( d \geq 3 \) with fixed-radius balls, to the case with bounded random radii.

Key words: continuum percolation, Boolean model, infinite cluster, capacity functional, percolation function, Reimer inequality, Margulis-Russo type formula

Foreword

This is a corrected version of our 2017 paper Last et al. (2017). The main issue needing correction is that Equations (4.4) and (4.5) of Last et al. (2017), the so-called stabilization and stopping radius properties of certain quantities $Z_K(\varphi, \varphi')$ and $R_{K,b}(\varphi, \varphi')$, can fail with the definitions of these quantities used in Last et al. (2017).

Indeed, suppose for example that $b = 1, K = \{o\}$ (where $o$ denotes the origin in $\mathbb{R}^d$) and $\varphi$ is such that $\text{dist}(o, Z(\varphi)) = \text{dist}(o, Z(\varphi')) \geq 99$, and moreover $Z(\varphi')$ provides a ‘bridge’ from $o$ to $Z(\varphi)$ (i.e., has a component that contains $o$ and also intersects $Z(\varphi)$).

Then using the definition in Last et al. (2017), we have $Z_K(\varphi, \varphi') = \emptyset$ so $R_{K,b}(\varphi, \varphi') = 1$. However, if we take $\psi = \varphi\big|_{B_9}$ then both (4.4) and (4.5) of Last et al. (2017) fail for $n = 1$. A version of this example was first suggested to us by Emil Schmitz. In his Master’s thesis, Schmitz (2022) describes a way to fix this error in dimension $d = 2$. We briefly indicated how to fix the issue in general dimensions in Last et al. (2024) (this work is independent of Schmitz (2022)). We present here a full corrected version of our paper (the fix in Last et al. (2024) itself contains a gap, which we fill in here; see the remark after (5.15).) We also took the opportunity to correct some unrelated, relatively minor slips along the way.

1 Introduction

The Boolean model is a fundamental model of random sets in stochastic geometry; see Hall (1988, Meester and Roy (1996, Stoyan et al. (1995, Schneider and Weil (2008). It is obtained by taking the union $Z$ of a collection of (in general, random) compact sets (known as grains) centered on the points of a homogeneous Poisson process of intensity $t$ in $d$-space. For a large class of grain distributions, it is known that for $t$ above a critical value $t_c$ that is dependent on the grain distribution, the resulting random set, denoted $Z(t)$, includes a unique infinite component, denoted $Z(\infty)$.

The random set $Z(\infty) = Z(\infty)(t)$ is an important and fascinating object of study. One way to investigate its distribution is through its capacity functional, defined as the set function $L \mapsto \theta_L(t) := \mathbb{P}\{Z(\infty)(t) \cap L \neq \emptyset\}$, defined for compact $L \subset \mathbb{R}^d$. If $L$ is a singleton, then $\theta(t) := \theta_{\{0\}}(t)$ is called the volume fraction of $Z(\infty)(t)$, and in the case where the grains are all translates of a fixed set $K_0$ (e.g. a unit ball), $\theta_{K_0}(t)$ is (loosely speaking) the proportion of grains that lie in $Z(\infty)$. More generally, the capacity functional of a random set and, in particular, of $Z(\infty)$, determines its distribution; see Schneider and Weil (2008).

In this article we investigate the capacity functional of $Z(\infty)$ as a function of the intensity $t$. We consider the case where the grains are balls with random radii with distribution $F_0$ for some probability measure $F_0$ on $\mathbb{R}^+$ with bounded support.

We show for any compact $L \subset \mathbb{R}^d$ that $\theta_L(t)$ is infinitely differentiable in $t$ for $t > t_c$ (it is identically 0 for $t < t_c$), thereby adding to earlier results on continuity of $\theta_L(t), t > t_c$, and give an explicit expression for the derivatives (Theorem 3.2). More generally, allowing $F_0$ to vary and viewing $\theta_L$ as a function of the measure $F := tF_0$, we show (Theorem 3.1) that it is infinitely differentiable in all directions with respect to the measure $F$ in the supercritical region of the cone of positive measures on a bounded interval.
We also prove (in Theorem 3.4) that \( \theta_L \) grows at least linearly in the right neighbourhood of the threshold \( t_c \). This is similar behaviour to that of the percolation function in discrete percolation models; see Grimmett (1999, Ch. 5) and the references therein. See Duminil-Copin and Tassion (2015) for a recent alternative proof of the discrete result, under the assumption of non-percolation at the critical point. It would be interesting to try to adapt this to the continuum.

In the course of proving the results mentioned above, we show (in Theorem 3.7) that if our Boolean model with random but bounded radii is supercritical in \( \mathbb{R}^d \), then it is also supercritical in a sufficiently thick slab. Previously, only the case with fixed radii had been considered, although the analogous result in the lattice is well known (Grinstead and Marstrand (1990)). Also noteworthy is the fact that our proof of Theorem 3.4 requires the continuum Reimer inequality (Gupta and Rao (1999)).

We believe that our methods could also be used to give smoothness of the \( n \)-point connectivity function as a function of \( t \) for \( t > t_c \). We also expect similar methods to be applicable for more general grains. See Section 7 for further discussion.

## 2 Preliminaries

Let \( d \in \mathbb{N} \) with \( d \geq 2 \). We shall be dealing with a stationary (spherical) Boolean model in \( \mathbb{R}^d \) which is described by means of a (marked) point process. Consider the space \( \mathbb{X} := \mathbb{R}^d \times \mathbb{R}_+ \) (where \( \mathbb{R}_+ := [0, \infty) \)), equipped with the Borel \( \sigma \)-field \( \mathcal{B}(\mathbb{X}) \) and the space \( \mathbb{N} \) of integer-valued locally finite measures \( \varphi \) on \( \mathcal{B}(\mathbb{X}) \). For \( b \in (0, \infty) \), let \( \mathbb{N}^b \) be the space of all \( \varphi \in \mathbb{N} \) that are supported by \( \mathbb{R}^d \times [0, b] \). Let \( \mathcal{N} \) denote the smallest \( \sigma \)-algebra of subsets of \( \mathbb{N} \) making the mappings \( \varphi \mapsto \varphi(D) \) measurable for all measurable \( D \subset \mathbb{X} \). It is often convenient to write \( z \in \varphi \) instead of \( \varphi(\{z\}) > 0 \).

A point process on \( \mathbb{X} \) is then a measurable mapping \( \Phi \) from some probability space \((\Omega, \mathcal{F}, \mathbb{P})\) into the measurable space \((\mathbb{N}, \mathcal{N})\). It is convenient to fix the mapping \( \Phi \) and to consider for any locally finite measure \( \mu \) on \( \mathcal{B}(\mathbb{X}) \) a probability measure \( \mathbb{P}_\mu \) on \((\Omega, \mathcal{F})\) such that the distribution \( \mathbb{P}_\mu(\{\Phi \in \cdot\}) \) of \( \Phi \) is that of a Poisson process with intensity measure \( \mu \). This means that under \( \mathbb{P}_\mu \) the point process \( \Phi \) has independent increments, with \( \Phi(D) \) Poisson distributed with mean \( \mu(D) \), for each bounded \( D \in \mathcal{B}(\mathbb{X}) \). See, e.g., Kallenberg (2002) or Last and Penrose (2016). Expectation under \( \mathbb{P}_\mu \) is denoted by \( \mathbb{E}_\mu \).

For \( r > 0 \), \( x \in \mathbb{R}^d \), we denote by \( B_r(x) \) the closed Euclidean ball of radius \( r \) centered at \( x \). Also we write 0 for the origin of \( \mathbb{R}^d \) and \( B_r \) for \( B_r(0) \).

Any \( \varphi \in \mathbb{N} \) is of the form \( \sum_i \delta_{z_i} = \sum_i \delta_{(z_i, r_i)} \), where the Dirac measure \( \delta_z \) at \( z \in \mathbb{X} \) is defined by \( \delta_z(D) = 1 \{ z \in D \} \) for every \( D \in \mathcal{B}(\mathbb{X}) \). We then define \( Z(\varphi) := \bigcup_i B_{r_i}(z_i) \). The balls \( B_{r_i}(z_i) \) are referred to as grains.

Connected components of \( Z(\varphi) \) are called clusters. Given \( \varphi \in \mathbb{N} \), let \( Z_\infty(\varphi) \) denote the union of the unbounded connected components of \( Z(\varphi) \), i.e. of the infinite clusters.

In this paper we deal with Poisson processes whose intensity measure is of the form \( \mu(d(x, r)) := dx \cdot F(dr) \), where \( dx \) is the \( d \)-dimensional Lebesgue measure and \( F \) is a finite measure on \( \mathbb{R}_+ \) (not necessarily a probability measure). When \( \mu \) is of this form, we shall write \( \mathbb{P}_F \) for \( \mathbb{P}_\mu \) and \( \mathbb{E}_F \) for \( \mathbb{E}_\mu \). Also let \( \Pi_F \) denote the distribution of \( \Phi \) under \( \mathbb{P}_F \), i.e. the probability measure on \((\mathbb{N}, \mathcal{N})\) given by \( \Pi_F(\cdot) = \mathbb{P}_F(\Phi \in \cdot) \). Set \( |F| = F(\mathbb{R}_+) \), the total mass of \( F \). Then \( |F| \) is called the density (or intensity) of the Poisson process under \( \mathbb{P}_F \).
We shall assume that $F$ has no atom at $\{0\}$; in any case the singletons do not contribute to percolation properties of $Z$ we study here.

Let $M$ (respectively $M_1, M_\pm$) denote the class of finite non-zero Borel measures (respectively, probability measures and finite signed measures) $F$ on $\mathbb{R}_+$ satisfying $F(\{0\}) = 0$. Given $b \in (0, \infty)$, we write $M^b$ (respectively $M_1^b, M_\pm^b$) for the measures that are supported by $[0, b]$, i.e. that satisfy $F([b, \infty)) = 0$. Let $M^2 := \cup_{b \in (0, \infty)} M^b$, the measures with bounded support. Likewise, set $M_1^1 := \cup_{b \in (0, \infty)} M_1^b$ and $M_\pm^1 := \cup_{b \in (0, \infty)} M_\pm^b$.

Let $F \in M$. Under $\mathbb{P}_F$, the set $Z := Z(\Phi)$ is called a Boolean model. It can be constructed, alternatively, by first generating an infinite independent sequence $\{R_i\}$ from the probability distribution $F(\cdot)/|F|$, and then placing balls of the corresponding radii at the points $\{X_i\}$ of a homogeneous Poisson point process with intensity $|F|$ in $\mathbb{R}^d$. This equivalence stems from the independent marking property of a Poisson process; for more details, see, e.g., Kallenberg (2002) or Last and Penrose (2016) Ch.5.

The point process $\Phi$ is stationary under $\mathbb{P}_F$, which means that for all $x \in \mathbb{R}^d$ we have $\mathbb{P}_F\{T_x \Phi \in \cdot\} = \mathbb{P}_F\{\Phi \in \cdot\}$, where for any $\mu \in \mathbb{N}$, the measure $T_x \mu \in \mathbb{N}$ is defined by

$$T_x \mu \{B \times C\} := \mu\{(B+x) \times C\},$$

with $B+x := \{y+x : y \in B\}$. Hence $Z(\Phi)$ is stationary as well, that is $\mathbb{P}_F\{Z+x \in \cdot\}$ does not depend on $x, x \in \mathbb{R}^d$. Since $Z_\infty(\Phi) + x = Z_\infty(T_{-x} \Phi)$ for all $x \in \mathbb{R}^d$, $Z_\infty(\Phi)$ is also stationary.

The volume fraction of the Boolean model is the probability that $Z$ covers a fixed point, for instance the origin 0, or in other words the proportion of space covered by grains:

$$\mathbb{P}_F\{0 \in Z\} = 1 - \exp\left[-\kappa_d \int r^d F(dr)\right],$$

where $\kappa_d := \pi^d/2\Gamma(d/2 + 1)$ stands for the volume of a $d$-dimensional unit ball.

Under $\mathbb{P}_F$ the sets $Z(\Phi)$ and $Z_\infty := Z_\infty(\Phi)$ are almost surely closed. They are random closed sets, see Molchanov (2005) or Schneider and Weil (2008). Our primary object of study here is $Z_\infty$. For each compact $L \subset \mathbb{R}^d$, let

$$\theta_L(F) := \mathbb{P}_F\{L \cap Z_\infty \neq \emptyset\},$$

so that $L \mapsto \theta_L(F)$ is the capacity functional of $Z_\infty$ under $\mathbb{P}_F$. As mentioned in Section 1, the capacity functional determines the distribution of $Z_\infty$. In particular we set

$$\theta(\cdot) := \theta_{\{0\}}(\cdot) = \mathbb{P}_F\{0 \in Z_\infty\} = \mathbb{E}_F|Z_\infty \cap [0, 1]^d|,$$

the volume fraction of $Z_\infty$ under $\mathbb{P}_F$ (also called the percolation function).

By ergodicity (see Meester and Roy (1996)), if $\theta(\cdot) > 0$ then $\mathbb{P}_F\{Z_\infty \neq \emptyset\} = 1$ and moreover the infinite cluster is $\mathbb{P}_F$-a.s. unique (i.e., $Z_\infty$ has only one connected component); see Meester and Roy (1996) Theorem 3.6). In this case we say that percolation occurs. Conversely, if $\theta(\cdot) = 0$ then $\mathbb{P}_F\{Z_\infty \neq \emptyset\} = 0$. Setting $U$ to be the class of $\varphi \in \mathbb{N}$ such that $Z(\varphi)$ has at most one unbounded component, we thus have

$$\mathbb{P}_F\{\Phi \in U\} = 1, \text{ for any } F \in M. \quad (2.1)$$

Given $F \in M$ (not necessarily a probability measure), consider the family of measures of the form $F^* = tF$ with $t > 0$. By a coupling argument, $\theta(tF)$ is nondecreasing in $t$. The critical value (or percolation threshold) $t_c(F)$ is the supremum of those $t$ such that
\( \theta(tF) = 0 \). If \( \int r^d F(dr) < \infty \) (for example, if \( F \in M^d \)), then \( 0 < t_c(F) < \infty \); see Gouéré (2008). If \( t_c(F) < 1 \) we say that \( F \) is strictly supercritical.

It is known that \( \theta(tF) \) is continuous in \( t \) at least for \( t \neq t_c(F) \), and right-continuous for all \( t \); see Meester and Roy (1996 Theorem 3.9). For \( d = 2 \), it is known Meester and Roy (1996 Theorem 4.5) that \( \theta(t_c(F)F) = 0 \) (and therefore \( \theta(tF) \) is continuous for all \( t \), and this is commonly believed to be true for \( d \geq 3 \) too.

**Remark 2.1.** For \( r \geq 0 \), the quantity \( \mathbb{P}_F\{B_r \subset Z_\infty(\Phi + \delta_{(0,r)})\} = \mathbb{P}_F\{B_r \cap Z_\infty \neq \emptyset\} = \theta_{B_r}(F) \) can be interpreted as the conditional probability (under \( \mathbb{P}_F \)) that \( B_r \) belongs to the infinite cluster given that \((0, r)\) belongs to \( \Phi \). Therefore \( \int \theta_{B_r}(F) F(dr)/|F| \) is the conditional (Palm) probability that a typical grain (centered at the origin) is a part of the infinite cluster, i.e. the proportion of grains belonging to the unbounded connected component.

Next we describe two important properties of Poisson processes which we use in this paper. One is the Mecke identity (see e.g. Last and Penrose (2016 Ch.4)):

\[
\mathbb{E}_\mu \int f(z, \Phi) \Phi(dz) = \mathbb{E}_\mu \int f(z, \Phi + \delta_z) \mu(dz) \tag{2.2}
\]

for any measurable \( f : X \times N \to \mathbb{R}_+ \). This identity characterises the Poisson process.

Another important result is the perturbation formula for functionals of Poisson processes, an analogue of the Margulis-Russo formula for Bernoulli fields. For bounded measurable \( f : N \to \mathbb{R} \), and \( z \in X \), define \( D_z f(\varphi) := f(\varphi + \delta_z) - f(\varphi) \), for all \( \varphi \in N \). For \( n \geq 2 \) and \((z_1, \ldots, z_n) \in X^n \) we define a function \( D_{z_1, \ldots, z_n}^n f : N(X) \to \mathbb{R} \) inductively by

\[
D_{z_1, \ldots, z_n}^n f := D_{z_1} D_{z_2, \ldots, z_n}^{n-1} f. \tag{2.3}
\]

The operator \( D_{z_1, \ldots, z_n}^n \) is symmetric in \( z_1, \ldots, z_n \); indeed, by induction

\[
D_{z_1, \ldots, z_n}^n f(\varphi) = \sum_{I \subset \{1, \ldots, n\}} (-1)^{|I|} f \left( \varphi + \sum_{i \in I} \delta_{z_i} \right) \tag{2.4}
\]

where \( |I| \) denotes the number of elements of \( I \).

**Proposition 2.2.** Let \( \mu \) be a locally finite measure and \( \nu \) a finite signed measure on \( B(X) \). Let \( f : N \to \mathbb{R} \) be measurable and bounded. If \( \mu + a\nu \) is a measure for some \( \nu > 0 \), then

\[
\frac{d^+}{ds} \mathbb{E}_{\mu + a\nu} f(\Phi) \bigg|_{s=0} = \int \mathbb{E}_\mu D_z f(\Phi) \nu(dz). \tag{2.5}
\]

If also \( \mu - a\nu \) is a measure, then \( \mathbb{E}_{\mu + a\nu} f(\Phi) \) is differentiable in \( s \) at \( s = 0 \).

The proof of this perturbation formula can be found in Zuev (1992 Theorem 2.1) (for the case \( \nu = \mu \)), for finite measures in Molchanov and Zuev (2000) Theorem 2.1, and for locally finite measures and square-integrable functions in Last (2014). It may also be found in Last and Penrose (2016).
3 Main results

3.1 Smoothness of the capacity functional

Our first result concerns differentiating the capacity functional $\theta$ with respect to the measure $F$. This can be useful to compare the percolation properties of different radius distributions. For example, in Gouéré and Marchand (2011) and in Meester et al. (1994) the percolation threshold for $F$ a Dirac measure (i.e. balls of fixed radius) has been compared with the percolation threshold for $F$ the sum of two Dirac measures (i.e. for balls of random radius with just two possible values), or with more general $F$. Gouéré and Marchand (2011) show that in sufficiently high dimensions the Dirac measure does not minimise the critical volume fraction (as had been previously conjectured) but do not quantify the phrase ‘sufficiently high’ and do not rule out the possibility that the Dirac measure minimises the critical volume fraction in low dimensions. With sufficient analytic tools, it might be possible to compare different radius distributions (perhaps with the same volume fraction) by calculus. For example, we could compare two measures $F_1$ and $F_2$ by passing continuously from one to the other.

Our result gives the directional derivative for $\theta_L(F)$ as we vary $F$. If we wish to keep the total measure (i.e., the density) constant then we need to add to $F$ a signed measure with total measure zero. More generally we may consider adding an arbitrary signed measure $G$ to $F$. We use notation for the classes of measures from Section 2 and $D^n$ from (2.3).

Theorem 3.1. Suppose that $F \in M^d$ with $t_c(F) < 1$, and $G \in M^d_{\pm}$ is such that $F + aG$ is a measure for some $a > 0$. Let $L \subset \mathbb{R}^d$ be compact. Then

$$\frac{d^+}{dh} \theta_L(F + hG) \bigg|_{h = 0} = \int \int \mathbb{P}_F \{L \cap Z_\infty(\Phi + \delta_{(x,r)}) \neq \emptyset, L \cap Z_\infty(\Phi) = \emptyset\} \times G(dr)dx,$$  

and the right-hand side of (3.1) is finite. If also $F - aG$ is a measure, then $\theta_L(F + hG)$ is infinitely differentiable in a neighbourhood of $h = 0$, then setting $\tilde{f}_L(\varphi) = 1\{L \cap Z_\infty(\varphi) \neq \emptyset\}$ for $\varphi \in \mathbb{N}$, for all $n \in \mathbb{N}$ we have

$$\frac{d^n}{dh^n} \theta_L(F + hG) \bigg|_{h = 0} = \int \cdots \int \mathbb{E}_F D^n_{(x_1,r_1),\ldots,(x_n,r_n)} \tilde{f}_L(\Phi) \times dx_1 G(dr_1) \cdots dx_n G(dr_n).$$  

We shall prove Theorem 3.1 in Section 5. The identity (3.1) tells us that the perturbation formula (2.3) remains valid for $f(\varphi) = 1\{L \cap Z_\infty(\varphi) \neq \emptyset\}$ with $\mu(dxdr) = dx F(dr)$ and $\nu(dxdr) = dx G(dr)$, though in this case both $\mu$ and $\nu$ are infinite (but $\sigma$-finite).

Our next theorem is a corollary of Theorem 3.1 and significantly adds to the known results mentioned in Section 2 concerning continuity of $\theta_L(tF)$ for fixed $F$, in the case of deterministically bounded radii. Recall that the Minkowski difference $A \ominus B$ of two sets $A, B \subset \mathbb{R}^d$ is defined by $\{x - y : x \in A, y \in B\}$. When $B = \{x\}$ for some $x \in \mathbb{R}^d$, we write simply $A - x$ for $A \ominus \{x\}$.
Theorem 3.2. Let \( F \in \mathcal{M}_1^d \), and let \( L \subset \mathbb{R}^d \) be compact. Then \( t \mapsto \theta_L(tF) \) is infinitely differentiable on \((t_c(F), \infty)\) and setting \( \tilde{f}_L(\varphi) = 1\{L \cap Z_\infty(\varphi) \neq \emptyset\} \) for all \( \varphi \in \mathbb{N} \), we have for \( t > t_c(F) \) and \( n \in \mathbb{N} \) that
\[
\frac{d^n \theta_L(tF)}{dt^n} = \int \cdots \int \mathbb{E}_{tF} D_{(x_1, r_1), \ldots, (x_n, r_n)}^{n} \tilde{f}_L(\Phi)\times dx_1 F(dr_1) \cdots dx_n F(dr_n). \tag{3.3}
\]
In particular, for \( t > t_c(F) \) we have
\[
\frac{d}{dt} \theta_L(tF) = \int \mathbb{P}_{tF} \{L \cap Z_\infty(\Phi + \delta(x, r)) \neq \emptyset, L \cap Z_\infty(\Phi) = \emptyset\} \times dx F(dr)
\]
\[
= \mathbb{E}_{tF} \int |(Z_\infty(\Phi + \delta(0,r)) \ominus L) \setminus (Z_\infty(\Phi) \ominus L)| F(dr). \tag{3.5}
\]

**Proof.** Let \( L \subset \mathbb{R}^d \) be compact. The infinite differentiability of \( \theta_L(tF) \), and the formula \( (3.3) \) for \( \frac{d^n \theta_L(tF)}{dt^n} \), follow from applying Theorem 3.1 to the measures \( F^* \) and \( G^* \) given by \( F^* = tF \) and \( G^* = F \); also \( (3.4) \) follows as a special case of \( (3.3) \). It remains to prove \( (3.5) \). By stationarity, \( T_x \Phi \) has the same distribution as \( \Phi \) under \( \mathbb{P}_{tF} \), so the right side of \( (3.4) \) equals
\[
\mathbb{E}_{tF} \int \mathbb{1}\{(L - x) \cap Z_\infty(\Phi + \delta(0,r)) \neq \emptyset, (L - x) \cap Z_\infty(\Phi) = \emptyset\} dx F(dr)
\]
\[
= \mathbb{E}_{tF} \int \mathbb{1}\{x \in (L \ominus Z_\infty(\Phi + \delta(0,r))) \setminus (L \ominus Z_\infty(\Phi))\} dx F(dr),
\]
and then \( (3.5) \) follows from the fact that for any Borel sets \( A, B, L \) we have \(|(L \ominus A) \setminus (L \ominus B)| = |(A \ominus L) \setminus (B \ominus L)|\). \( \square \)

**Remark 3.3.** Making use of the Mecke identity \( (2.2) \), we can also rewrite \( (3.4) \) as follows (see also Zuev (1992)):
\[
\frac{d}{dt} \theta_L(tF) = t^{-1} \mathbb{E}_{tF} \int \mathbb{1}\{L \cap Z_\infty(\Phi) \neq \emptyset, L \cap Z_\infty(\Phi - \delta(x, r)) = \emptyset\} \Phi(d(x,r)).
\]

### 3.2 Bounds for the capacity functional

Our next result provides a lower bound for the capacity functional of the infinite cluster. This bound is linear in the right neighbourhood of the critical value.

It is known for lattice percolation models that the percolation function grows at least linearly in the right neighbourhood of the threshold; see Chayes and Chayes (1986), or Grimmett (1999) and the references therein. Our result shows that this also holds for the spherical Boolean model.

**Theorem 3.4.** Let \( b > 0 \). Let \( F \in \mathcal{M}_1^d \) and let \( L \subset \mathbb{R}^d \) be compact. Set \( t_c := t_c(F) \) and \( \alpha := \mathbb{P}_{t_cF} \{B_b \subset Z(\Phi)\} \). Then
\[
\theta_L(tF) - \theta_L(t_c F) \geq \frac{\alpha(t - t_c) (1 - \theta_L(tF))}{t}, \quad t > t_c. \tag{3.6}
\]
Furthermore,
\[
\frac{\theta_L(tF) - \theta_L(t_c F)}{t - t_c} \geq \frac{\alpha(1 - \theta_L(t_c F))}{t_c} + o(1) \quad \text{as } t \downarrow t_c. \tag{3.7}
\]

Theorem 3.4 is proved in Section 6.

The bounds (3.6)-(3.7) also hold for the integrated percolation functions \( \int \theta_B, (tF) F(dr) \); see Remark 2.1. For a given \( F \), an explicit numerical lower bound for the right-hand side of (3.6) can be established by using the inequality
\[
1 - \theta_L(tF) \geq \mathbb{P}_{tF}\{L \cap Z = \emptyset\} = \exp\left[-t \int |B_r \ominus L| F(dr)\right]
\]
and applying a numerical estimation method for \( t_c \) such as that in Zuev and Sidorenko (1983), for example. Also, it is not difficult to estimate \( \alpha \) (the probability that \( B_0 \) is fully covered) explicitly from below.

Remark 3.5. Although the capacity functional \( t \mapsto \theta_L(tF) \) is believed to be continuous at the critical value \( t_c \), it is certainly not differentiable there. Indeed, if it is continuous, then \( \theta_L(t_c F) = 0 \) and the left-hand derivative of \( t \mapsto \theta_L(tF) \) at \( t_c \) vanishes. But Theorem 3.4 implies that the right-hand derivative, if it exists, is strictly positive.

Remark 3.6. Given the common belief for discrete percolation (see Grimmett (1999)), one might conjecture that \( \theta_L(tF) - \theta_L(t_c F) \sim (t - t_c)^\beta \) as \( t \downarrow t_c \) (at least in a logarithmic sense) for some critical exponent \( \beta > 0 \). If this holds, Theorem 3.4 implies \( \beta \leq 1 \).

### 3.3 Percolation in a slab when \( d \geq 3 \)

Given \( K > 0 \), let \( S(K) \) denote the slab \([0, K] \times \mathbb{R}^{d-1}\). An important result of Grimmett and Marstrand (1990) says that for Bernoulli lattice percolation if the parameter \( p \) is supercritical in \( \mathbb{Z}^d \), with \( d \geq 3 \), then for sufficiently large \( K \) the parameter \( p \) is also supercritical for the model restricted to a sufficiently large slab in \( \mathbb{Z}^d \).

To prove our results in the case \( d \geq 3 \), we need to adapt this result to the Boolean model. In the case where the balls have fixed radius, this was done in Tanemura (1993), and we now describe an extension to balls of random radius. This could potentially be of use elsewhere.

Given \( F \in \mathcal{M} \), let us denote by \( \Phi_F \) a Poisson process in \( X \) with distribution \( \Pi_F \), i.e. with \( \mathbb{P}\{\Phi_F \in \cdot\} = \mathbb{P}_F\{\Phi \in \cdot\} \). Given also any measurable function \( f : \mathbb{R}_+ \to \mathbb{R}_+ \), let us denote by \( \Phi_{F,F, f(\rho)} \) the image of \( \Phi_F \) under the mapping \( X \mapsto \sum_i \delta_{x_i, f(r_i)} \). Thus \( \Phi_{F,F, f(\rho)} \) has the same distribution as \( \Phi_{F,F, f^{-1}} \); it will be convenient for us to mention \( \rho \) in the notation, representing the radius of a ball in the system. For \( \varphi \in \mathcal{N} \) and \( A \in \mathcal{B}(X) \) let \( \varphi|_A \) denote the restriction of \( \varphi \) to \( A \), i.e. \( \varphi|_A(\cdot) = \varphi(\cdot \cap A) \). Finally, for \( B \subset \mathbb{R}^d \) write \([B]\) for \( B \times \mathbb{R}_+ \).

**Theorem 3.7.** Suppose \( d \geq 3 \) and let \( F \in \mathcal{M}^d \) with \( t_c(F) < 1 \). Then there exists \( K < \infty \) such that \( \mathbb{P}_F\{Z_\infty(\Phi|_S(K)) \neq \emptyset\} = 1 \), and
\[
\inf_{x \in S(K)} \mathbb{P}_F\{x \in Z_\infty(\Phi|_S(K))\} > 0. \tag{3.8}
\]
Proof. By assumption, \( F(\{0\}) = 0 \). By [Meester and Roy (1996) Theorem 3.7], for any \( b > 0 \) the value of \( t_c(F^b) \) depends continuously (in the weak topology) on \( F^b \in \mathcal{M}_0^1 \), so one can show that there exists \( a > 0 \) with \( t_c(F|_{[a,\infty)}) < 1 \), where \( F|_{[a,\infty)} \) denotes the restriction of the measure \( F \) to the interval \([a, \infty)\). Since there exist coupled Poisson point processes \( \Phi, \Phi' \) having distribution \( \Pi_F \) and \( \Pi_{F|_{[a,\infty)}} \) respectively with \( \Phi' \leq \Phi \) almost surely, it suffices to prove (3.8) using the measure \( F|_{[a,\infty)} \) rather than \( F \). In other words, we may assume without loss of generality that there exists \( a > 0 \) with \( F([0,a)) = 0 \), and then by scaling (see [Meester and Roy (1996)]) we can (and now do) assume \( a = 1 \).

For \( i = 3, 4, 5 \) choose \( t_i \) with \( t_c(F) < t_3 < t_4 < t_5 < 1 \). Then \( Z_\infty(\Phi_t,F) \neq \emptyset \) almost surely, so that by scaling, there exists \( \delta > 0 \) with \( 1/\delta \in \mathbb{N} \) such that also \( Z_\infty(\Phi_{t_i,F}(1-\delta)\rho) \neq \emptyset \) almost surely, and therefore also \( Z_\infty(\Phi_{t_i,F}\rho-\delta) \neq \emptyset \) since almost surely \( \rho \geq 1 \) so that \((1-\delta)\rho \leq \rho - \delta\).

Set \( [\rho]_\delta := \delta [\rho/\delta] \), i.e. the value of \( \rho \) rounded down to the nearest integer multiple of \( \delta \). Then \( [\rho]_\delta \geq \rho - \delta \), so that \( Z_\infty(\Phi_{t,F}[\rho]_\delta) \neq \emptyset \) almost surely. Note that since \( 1/\delta \in \mathbb{N} \) we have \([\rho]_\delta \geq 1 \) almost surely. By further scaling, we can (and do) choose \( \varepsilon > 0 \) such that \( Z_\infty(\Phi_{t,F}(1-2\varepsilon)[\rho]_\delta) \neq \emptyset \) almost surely.

Now let \( \eta = \varepsilon/(2d) \). Divide \( \mathbb{R}^d \) into half-open cubes denoted \( Q_z, z \in \mathbb{Z}^d, \) where \( Q_z \) has side length \( \eta \) and is centered at \( \eta z \). For \( x \in \mathbb{R}^d \) let \( \langle x \rangle_\eta \) denote the point at the center of the cube \( Q_z \) containing \( x \). For \( \varphi = \sum_i \delta_{(x_i,r_i)} \in \mathbb{N} \), let \( \langle \varphi \rangle_\eta := \sum_i \delta_{(\langle x_i \rangle_\eta,r_i)} \) (this counting measure can have multiplicities). Since \( |\langle x \rangle_\eta - x| \leq d\eta/2 \) for all \( x \in \mathbb{R}^d \), and since \( \eta \) is chosen so that \( d\eta < \varepsilon \), we have that \( Z_\infty(\Phi_{t,F}(1-\varepsilon)[\rho]_\delta) \neq \emptyset \) almost surely.

For \( t > 0 \), the occurrence of \( Z_\infty(\Phi_{t,F}(1-\varepsilon)[\rho]_\delta) \neq \emptyset \) is equivalent to existence of an infinite cluster in the following Bernoulli site percolation model on \( \mathbb{Z}^d \times \{1, 2, \ldots, \kappa\} \) for some \( \kappa \in \mathbb{N} \). Let \( r_1, \ldots, r_\kappa \) denote the possible values for \([\rho]_\delta \) (where \( \rho \) has distribution \( F(\cdot)/|F| \)), listed in increasing order. For \( 1 \leq i \leq \kappa \) set \( \pi_i := \mathbb{P}\{1-\varepsilon|[\rho]_\delta = r_i\} \). For \( y, z \in \mathbb{Z}^d \) and \( i, j \in \{1, \ldots, \kappa\} \), put \((y, i) \sim (z, j)\) if and only if \(|\eta y - \eta z| \leq r_i + r_j\). Let each site \((z, i)\) be occupied with probability \( p_{t,i} \), where we put \( p_{t,i} = 1 - \exp(-t|F|\eta^d\pi_i) \), independent of the other sites. Note that \( p_{t,i} \leq \kappa \) is supercritical, in that it strictly exceeds (in each entry) the vector \( (p_{t,i})_{i \leq \kappa} \) which also percolates.

By the result of [Grimmett and Marstrand (1990)] adapted to this site percolation model, there is a choice of \( K \) such that \( Z_\infty(\Phi_{F}(1-\varepsilon)|\rho|_\delta|_{\{S(K)\}}) \neq \emptyset \) almost surely. Therefore since \( dn \eta \leq \varepsilon \) we have \( Z_\infty(\Phi_{F}|_{\{S(K)\}}) \neq \emptyset \) almost surely. We may argue similarly to obtain (3.8), following the proof of Lemma 10.8 in [Penrose (2003)] with obvious modifications.

Let us describe how to adapt some of the steps of [Grimmett and Marstrand (1990)] to the site percolation model above. In Lemma 2 of [Grimmett and Marstrand (1990)], we may replace \((1 - p)^t\) by \((1 - \max_i p_{\lambda,i})^t\).

In Lemma 3 of [Grimmett and Marstrand (1990)], instead of the box \( B_m \) consider the box \( B_{2m[r_m]} \). Also the bound \((1 - p)^d k\) would be replaced by \((1 - \max_i p_{\lambda,i})^{-\kappa k}\) where \( B \) denotes the number of sites of \( \mathbb{Z}^d \) at distance at most \( 2r_\kappa \) from the origin.

In Lemma 4 of [Grimmett and Marstrand (1990)] we let \( T(n) \) denote the set of sites \((z, i)\) lying in \( B_n \cap \partial((\infty, n] \times \mathbb{Z}^{d-1}) \times \{1, \ldots, \kappa\} \) with all coordinates of \( z \) being nonnegative. \( \Box \)
4 A preparatory result

In this section, we present further notation followed by a key lemma (Lemma 4.2) which will be used repeatedly in the proof of Theorems 3.4 and 3.1. For $A \subset \mathbb{R}^d$ and $\varphi \in \mathbb{N}$, let $Z_A(\varphi)$ be the union of all the clusters of $Z(\varphi)$ which have non-empty intersection with $A$. In other words, set

$$Z_A(\varphi) := \bigcup_{i: x_i \leftrightarrow \varphi A} B_{r_i}(x_i), \quad \text{for} \quad \varphi = \sum_{i} \delta_{(x_i,r_i)},$$

(4.1)

where $x \leftrightarrow \varphi A$ means that $x$ lies in a component of $Z(\varphi)$ which intersects $A$.

Recall that $\varphi|_A$ denotes the restriction of $\varphi \in \mathbb{N}$ to $A \in \mathcal{B}(X)$ and $[B] = B \times \mathbb{R}_+$. Let $b \in (0, \infty)$. Given $\varphi, \varphi' \in \mathbb{N}^b$, after introducing

$$R'_{K,b}(\varphi, \varphi') := \min\{nd : n \in \mathbb{N}, Z_K(\varphi + \varphi') \subset B_{(n-1)b}\};$$

$$R''_{K,b}(\varphi, \varphi') := \min\{nb : n \in \mathbb{N}, Z_K(\varphi + \varphi'|_{B_{nb}}) \cap Z_\infty(\varphi) \neq \emptyset \}$$

$$= \min\{nb : n \in \mathbb{N}, K \cap Z_\infty(\varphi + \varphi'|_{B_{nb}}) \neq \emptyset \},$$

we define the following ‘radius of stabilization’:

$$R_{K,b}(\varphi, \varphi') := \min(R'_{K,b}(\varphi, \varphi'), R''_{K,b}(\varphi, \varphi')).$$

(4.2)

Here we use the convention $\min(\emptyset) := +\infty$ if needed. Also, below we shall sometimes write simply $R_K$ for $R_{K,1}$ and likewise $R'_K, R''_K$ for $R'_{K,1}, R''_{K,1}$ respectively.

It is straightforward to verify that the stopping radius property of $R_{K,b}$ (with respect to $\varphi'$) holds, i.e. for each $n \in \mathbb{N}$, if $R_{K,b}(\varphi, \varphi') = nb$ then for any $\psi \in \mathbb{N}_b$ we have

$$R_{K,b}(\varphi, \varphi'|_{B_{nb}} + \psi|_{\mathbb{R}^d, B_{nb}}) = R_{K,b}(\varphi, \varphi'|_{B_{nb}}).$$

(4.3)

The notions of stabilization and of stopping radius have proved fruitful in many other stochastic-geometrical contexts; see, for example, [Penrose (2007)].

For $F, G \in \mathcal{M}$ we denote by $\Phi_F, \Phi_G$ a pair of independent Poisson process with distribution $\Pi_F$ and $\Pi_G$, respectively, i.e. with $\mathbb{P}\{\Phi_F \in \cdot\} = \mathbb{P}_F\{\Phi \in \cdot\}$ and $\mathbb{P}\{\Phi_G \in \cdot\} = \mathbb{P}_G\{\Phi \in \cdot\}$. Recall from Section 3.3 the definition of the slab $S(K), K > 0$.

**Lemma 4.1.** Suppose $d \geq 3, b > 0$ and $F \in \mathcal{M}^b, G \in \mathcal{M}^b_\pm$ and $\varepsilon \in (0,1)$ are such that $F + \varepsilon G \in \mathcal{M}$, and $1 - \varepsilon > t_c(F)$. Then there exists $K \in (2b, \infty)$ and $\gamma \in (0,1/2)$ such that for all Borel $A \subset \mathbb{R}^d$, and $h \in (0, \varepsilon^2/2)$,

$$\max\{\mathbb{P}\{Z_{A}(\Phi_{F+\varepsilon G}\vert_{S(K)}) = \emptyset\},$$

$$\mathbb{P}\{Z_\infty(\Phi_{(1-\varepsilon)F}\vert_{S(K)}) \cap Z_A(\Phi_{\varepsilon F+\varepsilon G}\vert_{S(K)}) \neq \emptyset\}\} \geq \gamma.$$ 

(4.4)

**Proof.** Choose $K$ as in Theorem 3.7. Assume without loss of generality that $K \geq 2b$. Assume $\mathbb{P}\{Z_A(\Phi_{F+\varepsilon G}\vert_{S(K)}) \neq \emptyset\} \geq 1/2$ (otherwise (4.4) is immediate). Since $\mathbb{P}\{Y > 0\} \geq p\mathbb{P}\{X > 0\}$ for any $p \in (0,1)$ and Poisson variables $X, Y$ with $\mathbb{E}Y = p\mathbb{E}X$ (by Bernoulli’s inequality), also $\mathbb{P}\{Z_A(\Phi_{(1-\varepsilon)F}\vert_{S(K)}) \neq \emptyset\} \geq \varepsilon/4$. For $0 \leq h \leq \varepsilon^2/2$, we have

$$\varepsilon F + hG - (\varepsilon/2)(F + hG) = (\varepsilon/2)[F + (2h/\varepsilon)(1 - \varepsilon/2)G] \in \mathcal{M}.$$
Hence, also \( \mathbb{P}\{Z_A(\Phi'_{\epsilon F+hG}\mid S(K)) \neq \emptyset \} \geq \varepsilon/4 \). Given \( Z_A(\Phi'_{\epsilon F+hG}\mid S(K)) \neq \emptyset \), the set \( Z_A(\Phi'_{\epsilon F+hG}\mid S(K)) \) has non-empty intersection with \( S(K) \), and therefore by Theorem 3.7 and our choice of \( K \), the conditional probability that this set intersects with \( Z_{\infty}(\Phi_{(1-\varepsilon)F}\mid S(K)) \) is bounded below by a strictly positive constant \( \gamma_1 \). Hence we have (4.4) with \( \gamma = \gamma_1 \varepsilon/4 \).

Recall from Section 2 that \( \mathbb{M}^t \) denotes the class of measures on \((0, \infty)\) with bounded support. We now give the main result of this section.

**Lemma 4.2.** Let \( b \in (0, \infty) \), and suppose that \( F \in \mathbb{M}^b, G \in \mathbb{M}^b_+ \), and \( \varepsilon \in (0, 1) \) are such that \( t_\varepsilon(F) < 1 - \varepsilon \) and \( F + \varepsilon G \) is a measure. Then for any compact \( L \subset \mathbb{R}^d \), we have

\[
\limsup_{n \to \infty} \sup_{0 \leq h \leq \varepsilon^2/2} n^{-1} \log \mathbb{P}\{R_{L,b}(\Phi_{(1-\varepsilon)F}, \Phi'_{\epsilon F+hG}) > n\} < 0. \tag{4.5}
\]

Also, with \( 0 \) denoting the zero measure,

\[
\limsup_{n \to \infty} n^{-1} \log \mathbb{P}\{nb < R_{L,b}(0, \Phi_F) < \infty\} < 0. \tag{4.6}
\]

The \( \varepsilon^2 \) in the range of \( h \) in (4.5) arises because we need \( h \leq \varepsilon^2 \) to guarantee that \( \varepsilon F + hG \) is a measure. The fact that it is \( \varepsilon^2/2 \) rather than \( \varepsilon^2 \) in (4.5) is an artefact of the proof.

**Proof of Lemma 4.2.** Let \( F, G, \varepsilon \) be as in the statement of Lemma 4.2. First suppose \( d = 2 \). Using Corollary 4.1 of Meester and Roy (1996) as a starting-point, we can adapt the proof of Lemma 10.5 of Penrose (2003) to random radius balls, thereby showing that the probability that \( Z(\Phi_{(1-\varepsilon)F}) \) fails to cross the rectangle \([0, 3a] \times [0, a]\) decays exponentially in \( a \).

Given \( a > 0 \), specify a sequence \( D_1(a), D_2(a), \ldots \) of rectangles of aspect ratio 3, alternating between horizontal and vertical rectangles, with \( D_1(a) = [0, 3a] \times [0, a] \), and with \( D_n(a) \) crossing \( D_{n+1}(a) \) the short way for each \( n \). By the union bound and the exponential decay just mentioned, the probability that for some \( n \) there is no long-way crossing of \( D_n(a) \) in \( Z(\Phi_{(1-\varepsilon)F}) \) decays exponentially in \( a \). Hence the probability that \( Z(\Phi_{(1-\varepsilon)F}) \) fails to include a long-way crossing of \([0, 3a] \times [0, a]\) is exponentially decaying in \( a \). Likewise for the vertical rectangle \([0, a] \times [0, 3a]\).

Let \( E_a \) denote the event that \( Z(\Phi_{(1-\varepsilon)F}) \) includes long-way crossings of each of the rectangles \([-3a/2, -a/2] \times [-3a/2, 3a/2], [a/2, 3a/2] \times [-3a/2, 3a/2], [-3a/2, 3a/2] \times [-3a/2, -a/2] \) and \([-3a/2, 3a/2] \times [a/2, 3a/2] \) (whose union is the annulus \([-3a/2, 3a/2]^2 \setminus (-a/2, a/2)^2\)). By the preceding discussion, \( 1 - \mathbb{P}[E_a] \) decays exponentially in \( a \).

Suppose \( E_a \) occurs for some \( a \) with \( L \subset [-a/2, a/2]^2 \). Let \( h \geq 0 \). If \( R'_{L,b}(\Phi_{(1-\varepsilon)F}, \Phi'_{\epsilon F+hG}) > 3a + b \), then we must have \( Z'_L(\Phi_{(1-\varepsilon)F} + \Phi'_{\epsilon F+hG}\mid B_{3a+b}) \cap Z(\Phi_{(1-\varepsilon)F}) \neq \emptyset \), and therefore \( R'_{L,b}(\Phi_{(1-\varepsilon)F}, \Phi'_{\epsilon F+hG}) \leq 3a + 2b \). Hence \( R_{L,b}(\Phi_{(1-\varepsilon)F}, \Phi'_{\epsilon F+hG}) \leq 3a + 2b \) whenever \( E_a \) occurs, so the case \( d = 2 \) of (4.5) follows.

Now consider \( d \geq 3 \). Suppose \( 0 \leq h \leq \varepsilon^2/2 \). Choose \( b \in (0, \infty) \) with \( F \in \mathbb{M}^b \) and \( G \in \mathbb{M}^b_+ \). Set \( \Phi''_{F+hG} := \Phi_{(1-\varepsilon)F} + \Phi'_{\epsilon F+hG} \). Define the event \( A_u := \{R_{L,b}(\Phi_{(1-\varepsilon)F}, \Phi'_{\epsilon F+hG}) > u\} \). It suffices to prove that \( \mathbb{P}(A_u) \) decays exponentially in \( u \), uniformly over \( h \in [0, \varepsilon^2/2]\).

We now fix such \( h \). Let \( K \) be as in Lemma 4.1 and choose \( n_0 \in \mathbb{N} \) with \( L \subseteq B_{2b} \subset [-n_0K, n_0K]^d \).
For $n \in \mathbb{Z}$ let $S_n$ denote the slab $((n-1)K, nK] \times \mathbb{R}^{d-1}$ and let $H_n$ denote the half-space $\cup_{-\infty < m \leq n} S_m$. Given $u$ with $L \subset B_u$ and $n \geq n_0$, for $\varphi, \varphi' \in \mathbb{N}^b$ set

$$W_{u,n}(\varphi, \varphi') = Z_L((\varphi + \varphi')|[H_n \cap B_u])$$

and define the indicator functions

$$f_{u,n}(\varphi, \varphi') := 1\{Z((\varphi + \varphi')|[S_{n+1}]) \cap W_{u,n}(\varphi, \varphi') \neq \emptyset\};$$

$$g_{u,n}(\varphi, \varphi') := 1\{Z(\bigcup_{i=1}^n (\varphi + \varphi')|[S_{n+1}]) \cap W_{u,n}(\varphi, \varphi') = \emptyset\};$$

$$h_{u,n}(\varphi, \varphi') := 1\{Z_L((\varphi + \varphi')|[B_u]) \setminus H_n \neq \emptyset\}1\{R_{L,b}(\varphi, \varphi') > u\}.$$

Then we claim that $f_{u,n+1}(\varphi, \varphi') \leq f_{u,n}(\varphi, \varphi')$. Indeed,

$$h_{u,n}(\varphi, \varphi') \leq \prod_{m=n_0}^{n-2} f_{u,m}(\varphi, \varphi') g_{u,m}(\varphi, \varphi').$$

Denote by $\mathcal{F}_n$ the $\sigma$-field generated by $(\Phi(1-\varepsilon)|F|[H_n], \Phi'_{\varepsilon F+hG}|[H_n])$. If the conditional expectation of $f_{u,n}(\Phi(1-\varepsilon)|F', \Phi'_{\varepsilon F+hG})$ with respect to $\mathcal{F}_n$ is at least $1/2$, then by Lemma 4.1, with $A$ taken to be $W_{u,n}(\Phi(1-\varepsilon)|F', \Phi'_{\varepsilon F+hG})$ the conditional expectation of $1 - g_{u,n}(\Phi(1-\varepsilon)|F', \Phi'_{\varepsilon F+hG})$ is at least $\gamma$. (Lemma 4.1 is applicable when $A$ is a random closed set.) Hence, setting

$$V_{u,n} := f_{u,n}(\Phi(1-\varepsilon)|F', \Phi'_{\varepsilon F+hG}) g_{u,n}(\Phi(1-\varepsilon)|F', \Phi'_{\varepsilon F+hG}),$$

we have

$$\mathbb{E}[V_{u,n} | \mathcal{F}_n] \leq \max(1 - \gamma, 1/2) = 1 - \gamma.$$ 

Also, for each $n$, $V_{u,n+1}$ is $\mathcal{F}_n$-measurable and by (4.8) we have

$$\mathbb{E}[h_{u,n+2}(\Phi(1-\varepsilon)|F', \Phi'_{\varepsilon F+hG})] \leq \mathbb{E}\left[\prod_{i=n_0}^n V_{u,i}\right]$$

$$= \mathbb{E}\left[\mathbb{E}[V_{u,n}|\mathcal{F}_n] \times \prod_{i=n_0}^{n-1} V_{u,i}\right] \leq (1 - \gamma) \mathbb{E}\prod_{i=n_0}^{n-1} V_{u,i}$$

$$\leq \cdots \leq (1 - \gamma)^{n-n_0} \leq \exp(-\gamma(n-n_0)).$$

For each $i \in \{1, \ldots, d\}$ let $H_{n_i}^{i,+} := \{x \in \mathbb{R}^d : \pi_i(x) \leq Kn\}$ and $H_{n_i}^{i,-} := \{x \in \mathbb{R}^d : \pi_i(x) \geq -Kn\}$, where $\pi_i$ denotes projection onto the $i$th coordinate, set

$$h_{u,n,i}^{i,+}(\varphi, \varphi') := 1\{Z_L((\varphi + \varphi')|[B_u]) \setminus H_{n_i}^{i,+} \neq \emptyset\}1\{R_{L,b}(\varphi, \varphi') > u\},$$

define $h_{u,n,i}^{i,-}(\varphi, \varphi')$ similarly.
Now set \( \varphi := \Phi_{(1-\varepsilon)F} \) and \( \varphi' := \Phi'_{F+hG} \). Suppose \( A_u \) occurs; then \( R'_{L,b}(\varphi, \varphi') > u \) and therefore \( Z_{L}(\varphi + \varphi') \not\subseteq B_{u-b} \). This implies that for some \( i \leq d \) either \( Z_{L}((\varphi + \varphi')|B_{u}) \backslash H_{[u/dK]}^{i+} \neq \emptyset \) or \( Z_{L}((\varphi + \varphi')|B_{u}) \backslash H_{[u/dK]}^{-} \neq \emptyset \); also \( R'_{L,b}(\varphi, \varphi') > u \) and therefore \( h_{u,n}^{i+}(\varphi, \varphi') = 1 \) or \( h_{u,n}^{-}(\varphi, \varphi') = 1 \) for some \( i \in \{1, \ldots, d\} \). Therefore by applying the argument leading to (4.9) in each of the \( 2d \) positive or negative coordinate directions, and then the union bound, for \( u \) a multiple of \( b \) we have

\[
\mathbb{P}(A_u) \leq 2d\exp(-\gamma((u-b)/(dK)] - n_0 - 2)),
\]

which gives us the desired result (4.5) for \( d \geq 3 \).

To deduce (4.6), assume without loss of generality that \( \Phi_F \) is given as the superposition of \( \Phi_{(1-\varepsilon)F} \) and \( \Phi'_{F} \). If \( nb < R_{L,b}(0, \Phi_F) < \infty \), then \( R_{L,b}(\Phi_{(1-\varepsilon)F}, \Phi'_{F}) > nb \), so (4.6) will follow from taking \( h = 0 \) in (4.5). \( \square \)

5 Proof of Theorem 3.1

Suppose that \( b \in \mathbb{R}_+ \) and \( F \in M^b \) and \( G \in M^b_\pm \), with \( t_c(F) < 1 \) and \( F + aG \) a measure for some \( a > 0 \).

To ease notation, we shall assume additionally that \( b = 1 \); the result for a general \( b \) can be obtained by using the scaling property of the Boolean model, see, e.g., Meester and Roy (1996).

Choose \( \varepsilon \in (0, 1) \) with \( 1 - \varepsilon > t_c(F) \) and with \( F + \varepsilon G \) a measure. Keep \( F, G \) and \( \varepsilon \) fixed for the rest of this section.

Let \( G^+ \) and \( G^- \) be the positive and negative parts in the Hahn-Jordan decomposition of \( G \) (so that \( G^+ \) and \( G^- \) are mutually singular measures and \( G = G^+ - G^- \)). Let \( h \in [0, \varepsilon^2] \). Then \( \varepsilon F - hG^- \) is a measure. Recall from Section 2 that \( \Pi_F \) denotes the distribution of a Poisson process on \( \mathbb{R}^d \times \mathbb{R}_+ \) with intensity measure \( \mu(d(x, r)) = dx F(dr) \). Let \( \Phi_{(1-\varepsilon)F}, \Psi_{F-hG^-}, \Psi_{hG^-} \) and \( \Psi_{hG^+} \) be independent Poisson processes in \( \mathbb{R}^d \times \mathbb{R}_+ \) with respective distributions \( \Pi_{(1-\varepsilon)F}, \Pi_{F-hG^-}, \Pi_{hG^-} \) and \( \Pi_{hG^+} \). Set

\[
\Phi'_{F+hG} := \Psi_{F-hG^-} + \Psi_{hG^+};
\]

\[
\Phi_F := \Phi_{(1-\varepsilon)F} + \Psi_{F-hG^-} + \Psi_{hG^-};
\]

\[
\Phi_{F+hG} := \Phi_{(1-\varepsilon)F} + \Phi'_{F+hG},
\]

so that \( \Phi'_{F+hG}, \Phi_F \) and \( \Phi_{F+hG} \) are Poisson processes with distribution \( \Pi_{F+hG}; \Pi_F \), and \( \Pi_{F+hG} \), respectively. Also, for \( n \in \mathbb{N} \) define

\[
\Phi_{h,n} := \Psi_{F-hG^-} + \Psi_{hG^+}|B_n] + \Psi_{hG^-}|\mathbb{R}^d \setminus B_n],
\]

which is a Poisson process with intensity \( dx \times (\varepsilon F + hG)(dr) \) in \( B_n \), and with intensity \( dx \times \varepsilon F(dr) \) in \( \mathbb{R}^d \setminus B_n \). Since \( F \) and \( G \) are supported by \([0, 1] \), for \( \psi \in \mathbb{N}^1 \) we have

\[
Z(\Phi_{(1-\varepsilon)F} + \Phi_{h,n} + \psi) \cap B_{n-1} = Z(\Phi_{F+hG} + \psi) \cap B_{n-1}.
\]

(5.1)

Our next lemma gives us the first part (3.1) of Theorem 3.1, among other things.
Lemma 5.1. Let $L \subset \mathbb{R}^d$ be compact, and let $\psi \in \mathbb{N}^d$ with $\psi(\mathbb{X}) < \infty$. For $\varphi \in \mathbb{N}$, set $\bar{f}_{L,\psi}(\varphi) := 1\{L \cap \mathbb{Z}_\infty(\varphi + \psi) \neq \emptyset\}$. Then

$$
\frac{d^+}{dh} \mathbb{E}_{F+hG} \tilde{f}_{L,\psi}(\Phi)\bigg|_{h=0} = \int \int \mathbb{E}_F D(x,r) \tilde{f}_{L,\psi}(\Phi) G(dr) dx,
$$

(5.2)

and the right-hand side of (5.2) is finite. Also, given $h \in [0, \varepsilon^2]$ we have almost surely

$$
\tilde{f}_{L,\psi}(\Phi_{F+hG}) = \lim_{n \to \infty} \tilde{f}_{L,\psi}(\Phi_{(1-\varepsilon)F} + \Phi_{h,n}).
$$

(5.3)

Proof. To see (5.3), first suppose $\tilde{f}_{L,\psi}(\Phi_{F+hG}) = 1$. If also $\Phi_{F+hG} \in U$ (which is the case almost surely by (2.1)), there must be a path from $L$ through $Z(\Phi_{F+hG} + \psi) \cup (Z(\Phi_{(1-\varepsilon)F}) \setminus Z_{\infty}(\Phi_{(1-\varepsilon)F}))$ to $Z_{\infty}(\Phi_{(1-\varepsilon)F})$ if $L \cap Z_{\infty}(\Phi_{(1-\varepsilon)F}) \neq \emptyset$ we interpret this path as being empty). Choose such a path, and choose $m \in \mathbb{N}$ such that this path is contained in $B_{m-1}$. Then for $n \geq m$, by (5.1) we have $\tilde{f}_{L,\psi}(\Phi_{(1-\varepsilon)F} + \Phi_{h,n}) = 1$.

Conversely, suppose $\tilde{f}_{L,\psi}(\Phi_{F+hG}) = 0$. Then, recalling the definition (4.1) of $Z_L(\varphi)$, we have that $Z_L(\Phi_{F+hG} + \psi)$ is bounded so we can choose $m$ such that $Z_L(\Phi_{F+hG} + \psi) \subset B_{m-1}$. Then for $n \geq m$, by (5.1) we have $\tilde{f}_{L,\psi}(\Phi_{(1-\varepsilon)F} + \Phi_{h,n}) = 0$. Thus we have demonstrated (5.3).

For $h \in [0, \varepsilon^2]$ and $n \in \mathbb{N}$ set

$$
U_{h,n} = h^{-1}(\tilde{f}_{L,\psi}(\Phi_{(1-\varepsilon)F}) + \Phi_{h,n}^0) - \tilde{f}_{L,\psi}(\Phi_{(1-\varepsilon)F} + \Phi_{h,n-1}^0).
$$

By (5.3) and dominated convergence,

$$
\mathbb{E}\tilde{f}_{L,\psi}(\Phi_{F+hG}) = \lim_{n \to \infty} \mathbb{E}\tilde{f}_{L,\psi}(\Phi_{(1-\varepsilon)F} + \Phi_{h,n}^0).
$$

Also $\Phi_{(1-\varepsilon)F} + \Phi_{h,0}^0 = \Phi_F$ almost surely. Thus

$$
h^{-1}(\mathbb{E}\tilde{f}_{L,\psi}(\Phi_{F+hG}) - \mathbb{E}\tilde{f}_{L,\psi}(\Phi_F)) = \sum_{n=1}^{\infty} \mathbb{E}U_{h,n}.
$$

(5.4)

By Proposition (2.2) for each $n$ we have

$$
\lim_{h \to 0^+} \mathbb{E}U_{h,n} = \lim_{h \to 0^+} h^{-1}\mathbb{E}[\tilde{f}_{L,\psi}(\Phi_{(1-\varepsilon)F}) + \Phi_{h,n}^0] - \tilde{f}_{L,\psi}(\Phi_F)]
$$

$$
\quad - \lim_{h \to 0^+} h^{-1}\mathbb{E}[\tilde{f}_{L,\psi}(\Phi_{(1-\varepsilon)F} + \Phi_{h,n-1}^0) - \tilde{f}_{L,\psi}(\Phi_F)]
$$

$$
= \mathbb{E} \int \int_{B_n \setminus B_{n-1}} D(x,r) \tilde{f}_{L,\psi}(\Phi_F) dx G(dr).
$$

(5.5)

If we can take this limit through the sum on the right-hand side of (5.4), then we have the desired result (5.2). To justify this interchange, we seek to dominate the terms of (5.4) by those of a summable sequence, independently of $h$.

Note that $|U_{h,n}| \leq h^{-1}$. Also if $\Phi_{h,n}^0 = \Phi_{h,n-1}^0$ then clearly $U_{h,n} = 0$, so that

$$
\{U_{h,n} \neq 0\} \subset \{\Phi_{h,n}^0 \neq \Phi_{h,n-1}^0\}.
$$

(5.6)
Recall that we write $R_K$ for the radius of stabilization $R_{K,1}$ defined at (4.2). We assert the further event inclusion
\[
\{U_{h,n} \neq 0\} \subset \{R_L(\Phi_{(1-\varepsilon)F}, \Phi'_{\varepsilon F+hG} + \psi) > n - 1\} \cup \{\Phi_F \notin U\}. \tag{5.7}
\]
To see this, let $n \in \mathbb{N}$, and suppose $R_L(\varphi, \varphi') \leq n - 1$, where we now set
\[
\varphi = \Phi_{(1-\varepsilon)F}, \quad \varphi' = \Phi'_{\varepsilon F+hG} + \psi.
\]
By the definition of $R_L(\varphi, \varphi')$, we have either $R'_L(\varphi, \varphi') \leq n - 1$, or $R'_L(\varphi, \varphi') \leq n - 1$. We show that in both cases $U_{h,n} = 0$.

First suppose $R'_L(\varphi, \varphi') \leq n - 1$. In this case $L \cap Z_\infty(\varphi + \varphi'|[B_{n-1}]) \neq \emptyset$. From the definitions at the start of this section, we have that
\[
\Phi'_{h,n-1}|[B_{n-1}] = \Phi'_{\varepsilon F+hG}|[B_{n}]; \quad \Phi'_{h,n-1}|[B_{n-1}] = \Phi'_{\varepsilon F+hG}|[B_{n-1}]. \tag{5.8}
\]
Thus $\varphi'|[B_{n-1}] \leq \Phi_{h,n-1} + \psi$ and $\varphi'|[B_{n-1}] \leq \varphi'|[B_{n}] \leq \Phi_{h,n} + \psi$, so we obtain from the definition that $U_{h,n} = h^{-1}(1 - 1) = 0$ in this case.

Consider the other case, with $R'_L(\varphi, \varphi') \leq n - 1$. In this case we have $Z_L(\varphi + \varphi') \subset B_{n-2}$. Then any changes to $\varphi'$ outside $[B_{n-1}]$ do not cause any change to $Z_L(\varphi + \varphi')$, so for all locally finite point measures $\chi$ we have
\[
Z_L(\varphi + \varphi'|[B_{n-1}] + \chi|_{[\mathbb{R}^d \setminus B_{n-1}]} \cap Z_\infty(\varphi) = \emptyset,
\]
and from this, using (5.8) we can deduce that
\[
\hat{f}_{L,\psi}(\varphi + \Phi_{h,n-1}) = 1\{L \cap Z_\infty(\varphi + \varphi'|[B_{n-1}] + (\Phi_{h,n-1} + \psi)|_{[\mathbb{R}^d \setminus B_{n-1}]} \neq \emptyset\} = 0,
\]
and likewise $\hat{f}_{L,\psi}(\varphi + \Phi'_{h,n}) = 0$, so that $U_{h,n} = h^{-1}(0 - 0) = 0$. This justifies (5.7).

The event $\{\Phi_{h,n} \neq \Phi'_{h,n-1}\}$ is independent of the event $\{R_L(\Phi_{(1-\varepsilon)F}, \Phi'_{\varepsilon F+hG} + \psi) \leq n - 1\}$, by the stopping radius property (4.3), and therefore also independent of the complementary event $\{R_L(\Phi_{(1-\varepsilon)F}, \Phi'_{\varepsilon F+hG} + \psi) > n - 1\}$. Also we have the event inclusion:
\[
\{R_L(\Phi_{(1-\varepsilon)F}, \Phi'_{\varepsilon F+hG} + \psi) > n - 1\} \subset \{R_{LZ}(\psi)(\Phi_{(1-\varepsilon)F}, \Phi'_{\varepsilon F+hG}) > n - 1\}.
\]

Therefore by (5.6), (5.7) and (2.1) we have
\[
E|U_{h,n}| \leq h^{-1}\mathbb{P}\{\Phi_{h,n} \neq \Phi'_{h,n-1}\} \mathbb{P}\{R_{LZ}(\psi)(\Phi_{(1-\varepsilon)F}, \Phi'_{\varepsilon F+hG}) > n - 1\}.
\]
Also there is a constant $c' \in (0, \infty)$ such that $\mathbb{P}\{\Phi_{h,n} \neq \Phi'_{h,n-1}\} \leq n^{d-1}h c'$. Hence by Lemma 4.2 there is a constant $c \in (0, \infty)$ (independent of $n$ and $h$, provided $0 \leq h \leq \varepsilon^2/2$) such that
\[
E|U_{h,n}| \leq c n^{d-1} \times \exp(-c^{-1} n)
\]
which is summable in $n$. Hence by (5.4), (5.5) and dominated convergence we have (5.2). This also shows that the right side of (5.2) is finite. 

\[\square\]
Proof of Theorem 3.1. We prove the result just for $b = 1$. The first part (3.1) holds by Lemma 5.1. To prove the second part we take $F, G$ and $\varepsilon$ as before but now assume additionally that $F - \varepsilon G$ is a measure. Let $L \subset \mathbb{R}^d$ be compact. As above, for each $\varphi \in \mathbb{N}$ and each $\psi \in \mathbb{N}_1$ with $\psi(X) < \infty$, set $\tilde{f}_{L,\psi}(\varphi) := 1\{L \cap Z_\infty(\varphi + \psi) \neq \emptyset\}$, and set $\tilde{f}_L(\varphi) := \tilde{f}_{L,0}(\varphi) = 1\{L \cap Z_\infty(\varphi) \neq \emptyset\}$. We shall prove by induction that for $n \in \mathbb{N}$ and $h \in (-\varepsilon^2, \varepsilon^2)$, we have

$$
\frac{d^n}{dh^n} \theta_L(F + hG) = \int \cdots \int \mathbb{E}_{F+hG} D^n_{(x_1, \ldots, (x_n, r_n)} \tilde{f}_L(\Phi) dx_1 G(dr_1) \cdots dx_n G(dr_n),
$$

which implies (3.2).

First consider $n = 1$. Then (5.9) holds for the right derivative at $h = 0$ by Lemma 5.1. Also, by applying this fact to $-G$ instead of $G$ we have that (5.9) holds for the left derivative at $h = 0$ too, so (5.9) holds at $h = 0$. Therefore (5.9) also holds at other $h \in (-\varepsilon^2, \varepsilon^2)$ because we can apply the case $h = 0$ of (5.9) to $F_\ast$ and $G_\ast$, given by $F_\ast = F + hG$, and $G_\ast = G$. Note that $F_\ast$ is strictly supercritical because $F_\ast = (1-\varepsilon)F + \varepsilon(F + (h/\varepsilon)G)$ and $\varepsilon(F + (h/\varepsilon)G)$ is a measure since $|h| < \varepsilon^2$.

Now we perform the inductive step. Let $n \in \mathbb{N}$, and suppose (5.9) holds for all $h \in (-\varepsilon^2, \varepsilon^2)$. Then for $0 < h < \varepsilon^2$,

$$h^{-1}(\frac{d^n}{ds^n} \theta_L(F + sG) \bigg|_{s=h} - \frac{d^n}{ds^n} \theta_L(F + sG) \bigg|_{s=0}) = \int \cdots \int u_{x_1, r_1, \ldots, x_n, r_n}(h) dx_1 G(dr_1) \cdots dx_n G(dr_n),
$$

where we set

$$u_{x_1, r_1, \ldots, x_n, r_n}(h) := h^{-1} \left( \mathbb{E} D^n_{(x_1, r_1), \ldots, (x_n, r_n)} \tilde{f}_L(\Phi_{F+hG}) - \mathbb{E} D^n_{(x_1, r_1), \ldots, (x_n, r_n)} \tilde{f}_L(\Phi_F) \right).$$

Applying Lemma 5.1 to the function $D^n_{(x_1, r_1), \ldots, (x_n, r_n)} \tilde{f}_L$ (expressed as a sum as in (2.4)) gives us as $h \to 0$ that

$$u_{x_1, r_1, \ldots, x_n, r_n}(h) \to \int \int \mathbb{E} D^{n+1}_{(x, r), (x_1, r_1), \ldots, (x_n, r_n)} \tilde{f}_L(\Phi_F) dx G(dr).$$

For $1 \leq i \leq n$, write $z_i$ for $(x_i, r_i)$. By (5.3) applied to $\tilde{f}_{L, \psi}$ for each $\psi \in \mathbb{N}_1$ with $\psi \leq \sum_{i=1}^n \delta_{z_i}$, and dominated convergence, we have for $(z_1, \ldots, z_n) \in X^n$ and $|h| < \varepsilon^2$ that

$$u_{z_1, \ldots, z_n}(h) = h^{-1} \left( \lim_{m \to \infty} \mathbb{E} D^n_{z_1, \ldots, z_n} \tilde{f}_L(\Phi_{(1-\varepsilon)F + \Phi'_h,m}) - \mathbb{E} D^n_{z_1, \ldots, z_n} \tilde{f}_L(\Phi_F) \right)$$

$$= \sum_{m=1}^\infty \mathbb{E} V(h, m, z_1, \ldots, z_n),
$$

(5.12)
where we set

\[ V(h, m, z_1, \ldots, z_n) := h^{-1}\left(D^n_{z_1, \ldots, z_n} f_L(\Phi_{(1-\varepsilon)F} + \Phi'_{h,m}) - D^n_{z_1, \ldots, z_n} f_L(\Phi_{(1-\varepsilon)F} + \Phi'_{h,m-1}) \right). \]  

(5.13)

Now, \(|V(h, m, z_1, \ldots, z_n)| \leq 2^n h^{-1}\) and clearly we have

\[ \{V(h, m, z_1, \ldots, z_n) \neq 0\} \subset \{\Phi'_{h,m} \neq \Phi'_{h,m-1}\}. \]  

(5.14)

Set \(M = \max(m, |x_1|, \ldots, |x_n|)\). Suppose \(M \geq (2n + 4)(\operatorname{diam}(L \cup \{0\}) + 4)\). Choose \(I \in \{1, \ldots, 2n + 3\}\) such that the annulus

\[ \Gamma_{M,n,I} := B_{(I+1)M/(2n+4)} \setminus B_{IM/(2n+4)} \]

intersects none of the balls \(B_{r_1}(x_1), \ldots, B_{r_n}(x_n)\) and also does not intersect the annulus \(B_{m+1} \setminus B_{m-2}\); to be definite, choose the smallest such \(I\).

Cover the boundary \(\partial B_{(I+0.5)M/(2n+4)}\) of the ball \(B_{(I+0.5)M/(2n+4)}\) with a deterministic collection of unit balls \(C_1, \ldots, C_k(M)\), each \(C_j\) with center \(w_j\) in \(\partial B_{(I+0.5)M/(2n+4)}\), with \(k(M) = O(M^{d-1})\). Let \(\tau_j(\varphi)\) denote the shifted point measure \(\varphi(\cdot + w_j)\). Define the event

\[ A'_{h,m,z_1,\ldots,z_n} := \bigcup_{j=1}^{k(M)} \{R_{B_1}(\tau_j(\Phi_{(1-\varepsilon)F}), \tau_j(\Phi'_{h,m})) \geq (M/(4n + 8) - 2)\}. \]  

(5.15)

We remark that our definition of \(A'_{h,m,z_1,\ldots,z_n}\) is different from the one suggested in [Last et al. (2024)]; this is because we subsequently found some further issues with verifying [5.16] below using that definition.

Write just \(\Phi\) for \(\Phi_{(1-\varepsilon)F}\). Note that the events \(\{\Phi'_{h,m} \neq \Phi'_{h,m-1}\}\) and \(A'_{h,m,z_1,\ldots,z_n}\) are independent. Indeed, the first event is determined by \(\Psi_{hG^+} |_{B_m \setminus B_{m-1}}\) and \(\Psi_{hG_-} |_{B_m \setminus B_{m-1}}\), while the second event is determined by \(\Phi, \Psi_{E-hG},\) and the restrictions of \(\Psi_{hG^+}\) to \(\Gamma_{M,n,I}\), and the annuli \(B_m \setminus B_{m-1}\) and \(\Gamma_{M,n,I}\) are disjoint. We will show next that

\[ \{V(h, m, z_1, \ldots, z_n) \neq 0\} \subset A'_{h,m,z_1,\ldots,z_n}. \]  

(5.16)

To justify this, observe first that by the definition of \(M\), at least one of the sets \(B_{r_1}(x_1), \ldots, B_{r_n}(x_n), B_{m+2} \setminus B_{m-1}\) is exterior to \(B_{(I+1)M/(2n+4)}\), i.e. has empty intersection with it.

Suppose that \(A'_{h,m,z_1,\ldots,z_n}\) does not occur. Suppose also that one of the balls \(B_{r_i}(x_i)\) (say the ball \(B_{r_1}(x_1)\)) is exterior to \(B_{(I+1)M/(2n+4)}\); then for any \(\psi \in \mathbb{N}\) with \(\psi \leq \sum_{i=2}^{n} \delta_{z_i}\), we claim that

\[ \tilde{f}_{L,\psi}(\Phi + \Phi'_{h,m}) = \tilde{f}_{L,\psi}(\Phi + \Phi'_{h,m} + \delta_{z_1}). \]  

(5.17)

Indeed, suppose otherwise; then the left-hand side of (5.17) equals zero, while the right-hand side equals 1. Then there must exist a bounded component of \(Z(\Phi + \Phi'_{h,m} + \psi)\) that connects \(L\) to \(B_{r_1}(x_1)\). This component must cross the annulus \(\Gamma_{M,n,I}\) and therefore passes through \(C_j\) for some \(j \leq k(M)\); hence for this choice of \(j\) we have \(R'_{B_1}(\tau_j(\Phi), \tau_j(\Phi'_{h,m})) \geq (M/(4n + 8)) - 2\). Therefore since we assume \(A'_{h,m,z_1,\ldots,z_n}\) does not occur, we must have
\[ R'_{B_1}(\tau_j(\Phi), \tau_j(\Phi'_{h,m})) < (M/(4n + 8)) - 2. \]

Since \( B(w_j, (M/(4n + 8)) - 2) \subset \Gamma_{M,n,i} \), this implies

\[ C_j \cap Z_\infty(\Phi + \Phi_{h,m}|_{\Gamma_{M,n,i}}) \neq \emptyset, \tag{5.18} \]

and therefore \( L \) is connected (via \( C_j \)) to \( Z_\infty(\Phi + \Phi_{h,m} + \psi) \) so the left side of \( (5.17) \) equals 1, which is a contradiction.

By \( (5.17) \), we have \( D_{z_1,\ldots,z_n}^n \tilde{f}_L(\Phi + \Phi_{h,m}) = 0 \), and we can show similarly that \( D_{z_1,\ldots,z_n}^n \tilde{f}_L(\Phi + \Phi'_{h,m}) = 0 \), so that \( V(h, m, z_1, \ldots, z_n) = 0 \) in this case.

Now suppose instead that the annulus \( B_{m+1} \setminus B_{m-2} \) is exterior to \( B_{(I+1)M/(2n+4)} \), and as before that \( A_{h,m,z_1,\ldots,z_n} \) does not occur. Let \( \psi \in \mathbb{N} \) with \( \psi \leq \sum_{i=1}^n \delta_{z_i} \). Then we claim that

\[ \tilde{f}_L(\Phi + \Phi'_{h,m}) = \tilde{f}_L(\Phi + \Phi'_{h,m-1}). \tag{5.19} \]

Indeed, suppose \( \tilde{f}_L(\Phi + \Phi'_{h,m}) = 1 \) and \( \tilde{f}_L(\Phi + \Phi'_{h,m-1}) = 0 \). Then there must be a bounded component of \( Z(\Phi + (\Phi_{h,m} + \psi)|_{B_{m-1}}) \) connecting \( L \) to \( \mathbb{R}^d \setminus B_{m-2} \). This component must pass through \( C_j \) for some \( j \leq k(M) \), so that for this \( j \) (as in the previous case) \( R'_{B_1}(\tau_j(\Phi), \tau_j(\Phi'_{h,m})) \geq (M/(4n + 8)) - 2 \) and hence \( R'_{B_1}(\tau_j(\Phi), \tau_j(\Phi'_{h,m})) < (M/(4n + 8)) - 2 \), so that \( (5.18) \) holds. But this implies \( L \) is connected (via \( C_j \)) to \( Z_\infty(\Phi + (\Phi_{h,m} + \psi)|_{B_{m-1}}) = Z_\infty(\Phi + (\Phi_{h,m-1} + \psi)|_{B_{m-1}}) \), so both sides of \( (5.19) \) are equal to 1, which is a contradiction. We can obtain a contradiction similarly if \( \tilde{f}_L(\Phi + \Phi'_{h,m}) = 0 \) and \( \tilde{f}_L(\Phi + \Phi'_{h,m-1}) = 1 \), so we have justified the claim \( (5.19) \). By \( (5.19) \) we have \( V(h, m, z_1, \ldots, z_n) = 0 \) in this case too. Together with the previous two paragraphs, this implies the assertion \( (5.16) \).

We show next that for \( n \) and \( L \) fixed there is a constant \( c \) such that for all \( m \), all \( z_1, \ldots, z_n \in \mathbb{R}^d \times [0, 1] \) and all \( h \in (-\varepsilon^2/2, \varepsilon^2/2) \) we have

\[ \mathbb{P}[A_{h,m,z_1,\ldots,z_n}] \leq c \exp(-c^{-1}M). \tag{5.20} \]

Assume again that \( M \geq (2n+4)(\text{diam}(L \cup \{0\}) + 4) \). For each \( j \) let \( C'_j := B(w_j, M/(4n + 8)) \). Since the restriction of Poisson process \( \Phi'_{h,m} \) or \( \Phi'_{h,m-1} \) to \( [C'_j] \) has intensity of product form (either \( dx \times (\varepsilon F + hG)(dr) \) or \( dx \times \varepsilon F(dr) \), depending on whether or not the annulus \( B_m \setminus B_{m-1} \) is exterior to \( B_{(I+1)M/(2n+4)} \), we can use the union bound and Lemma 4.2 to obtain \( (5.20) \).

Using \( (5.14) \), \( (5.16) \) and \( (5.20) \), we obtain that there is a finite constant (again denoted \( c \), and depending on \( n \)) such that

\[ \mathbb{E}[V(h, m, z_1, \ldots, z_n)] \leq \mathbb{P}\{\Phi'_{h,m} \neq \Phi'_{h,m-1}\} \mathbb{P}\{A'_{h,m,z_1,\ldots,z_n}\} \leq cm^{d-1}\exp(-(m + \max(|x_1|, \ldots, |x_n|))/c), \]

which is summable in \( m \) with the sum being integrable in \( (z_1, \ldots, z_n) \). Then using \( (5.12) \) and dominated convergence we can take the limit \( (5.11) \) inside the integral \( (5.10) \), so that

\[ \frac{d^n}{dh} \frac{d^n}{dh} \theta_L(F + hG) \bigg|_{h=0} = \mathbb{E}_F \int \cdots \int D_{(x,r),(x_1,r_1),\ldots,(x_n,r_n)}^{n+1} \tilde{f}_L(\Phi) \times dxG(dr) \times dx_1G(dr_1) \cdots dx_nG(dr_n). \]
6 Proof of Theorem 3.4

Given a graph $\mathbf{G} = (V, E)$, and given $v \in V$, let us denote by $\mathbf{G} \setminus v$ the graph $\mathbf{G}$ with $v$ and all edges incident to $v$ removed. If $u, v, w$ are distinct vertices of $\mathbf{G}$, let us say vertex $w$ is $(u, v)$-pivotal if $u$ and $v$ lie in the same component of $\mathbf{G}$ but different components of $\mathbf{G} \setminus w$.

Lemma 6.1. Suppose $\mathbf{G} = (V, E)$ is a finite connected graph, and $u, v \in E$ with $u \neq v$. Then either $\mathbf{G}$ has at least one $(u, v)$-pivotal vertex, or there exist at least two vertex-disjoint paths in $\mathbf{G}$ from $u$ to $v$. Also, in the first case, every path from $u$ to $v$ in $\mathbf{G}$ passes through the $(u, v)$-pivotal vertices in the same order.

Proof. The first assertion is an immediate consequence of Menger’s theorem (see e.g. Bollobás (1979)).

To see the second assertion, suppose $w, w'$ are distinct $(u, v)$-pivotal vertices, and there is a path from $u$ to $v$ passing through $w$ before $w'$, and another such path passing through $w'$ before $w$. Then following the first path from $u$ as far as $w$, and then the second path from $w$ to $v$, we obtain a path from $u$ to $v$ avoiding $w'$; hence $w'$ is not $(u, v)$-pivotal, which is a contradiction. \qed

Proof of Theorem 3.4. Our proof uses ideas from Chayes and Chayes (1986). We start by introducing some notation. Fix $b > 0$, $F \in \mathcal{M}_b^1$ and compact $L \subset \mathbb{R}^d$. Since $F$ is fixed, we write $\theta_L(t)$ for $\theta(tF)$ in this proof. By a path in a configuration $\varphi \in \mathcal{N}$ we mean a finite or infinite sequence $K_1, K_2, \ldots$ of distinct grains such that $K_i = B_r(x_i)$ for some $(x_i, r_i) \in \varphi$ and $K_i \cap K_{i+1} \neq \emptyset$ for all $i \geq 1$ with $K_{i+1}$ part of the sequence. A path intersects a subset of $\mathbb{R}^d$, if one of its constituent grains intersects this set. If $A, A'$ are disjoint subsets of $\mathbb{R}^d$ and a path intersects both $A$ and $A'$, then we say the path joins $A$ to $A'$. We shall say that two paths ($K_1, K_2, \ldots$) and ($K'_1, K'_2, \ldots$) in $\varphi$ are disjoint if $K_i \neq K'_j$ for all $i, j$.

For $n \in \mathbb{N}$ introduce events that there is a path joining $L$ to the complement of $B_n$ or to infinity,

$$J^n_L := \{ \varphi \in \mathcal{N} : Z_L(\varphi) \setminus B_n \neq \emptyset \}; \quad J_L := \{ \varphi \in \mathcal{N} : L \cap Z_\infty(\varphi) \neq \emptyset \},$$

where the notation $Z_L$ is as defined in (4.1). Assume from now on that $n$ is so large that $L \subset B_{n-2b}$. If $\varphi \in J^n_L$, but $(x, r) \in \varphi$ is such that $\varphi - \delta(x, r) \notin J^n_L$, we say that the grain $B(x, r)$ is pivotal for $J^n_L$ in the configuration $\varphi$.

Let $\theta_L'(t) := \mathbb{P}_{tF}\{ \Phi \in J^n_L \}$. We claim that when $\varphi \in J^n_L$, either there are at least two disjoint paths from $L$ to $\mathbb{R}^d \setminus B_n$ in $\varphi$ or there is at least one pivotal grain for $J^n_L$ and there is a unique last pivotal grain for $J^n_L$ when counting from $L$. To see this claim, apply Lemma 6.1 to the intersection graph of the set

$$B_n = \{ B_r(x_i) : (x_i, r_i) \in \varphi \text{ such that } B_r(x_i) \cap B_n \neq \emptyset \} \cup \{ L, \mathbb{R}^d \setminus B_n \}. \quad (6.1)$$
Let $\varphi \in \mathbb{N}$ and $n \in \mathbb{N}$. Suppose there is a unique last pivotal grain for $J^n_L$ and denote this last pivotal grain by $K := B_r(x)$. If $K \subset B_n$, then there exist three disjoint paths in $\varphi - \delta(x,r)$: one which joins $L$ to $K$ and two which join $K$ to $\mathbb{R}^d \setminus B_n$. If not (i.e. if $K \not\subset \mathbb{R}^d \setminus B_n$), there is still a path joining $K$ to $L$. Even in this case we say that there are two disjoint paths joining $K$ to $\mathbb{R}^d \setminus \partial B_n$, which are just both empty; see Figure 1. We denote this last pivotal grain by $K := B_r(x)$. If $K \subset B_n$, then there exist three disjoint paths in $\varphi - \delta(x,r)$: one which joins $L$ to $K$ and two which join $K$ to $\mathbb{R}^d \setminus B_n$. If not (i.e. if $K \not\subset \mathbb{R}^d \setminus B_n$), there is still a path joining $K$ to $L$. Even in this case we say that there are two disjoint paths joining $K$ to $\mathbb{R}^d \setminus \partial B_n$, which are just both empty; see Figure 1. We denote this last pivotal grain starting from $L$ by $K$.

then have

$$
\theta^n_L(t) = \mathbb{P}_t \{ \text{there are two disjoint paths in } \phi \text{ joining } L \text{ to } \mathbb{R}^d \setminus B_n \} \\
+ \mathbb{E}_t \int \mathbf{1} \{ B_r(x) \text{ is the last pivotal grain for } J^n_L \text{ in } \phi \} F(d(x,r)) \\
\leq (\theta^n_L(t))^2 + t \iint \mathbb{P}_t \{ B_r(x) \text{ is the last pivotal grain for } J^n_L \text{ in } \phi + \delta(x,r) \} \\
\times dx F(dr),
$$

where we have used the B-K inequality [Meester and Roy (1996) Th. 2.3] to bound the first term from above and the Mecke identity (2.2) for the second term. Now $B_r(x)$ is the last pivotal grain for $J^n_L$ in $\Phi + \delta(x,r)$ if and only if there are two disjoint paths in the configuration $\Phi + \delta(x,r)$, one of them joining $B_r(x)$ and $\mathbb{R}^d \setminus B_n$ (possibly empty, if $B_r(x) \setminus B_n \neq \emptyset$), and the other one joining $L$ and $\mathbb{R}^d \setminus B_n$ and using $B_r(x)$, and all paths joining $L$ to $\mathbb{R}^d \setminus B_n$ use $B_r(x)$. We claim that this is the same as saying the events

$$E_{n,x,r} := \{ \varphi : \varphi + \delta(x,r) \in J^n_L, \varphi \notin J^n_L \}$$

and $J^n_{B_r(x)}$ occur disjointly in the sense of Gupta and Rao (1999), so that by the continuum Reimer inequality in that paper, we get

$$\theta^n_L(t) \leq (\theta^n_L(t))^2 + t \iint \mathbb{P}_t \{ \phi \in E_{n,x,r} \} \mathbb{P}_t \{ \phi \in J^n_{B_r(x)} \} dx F(dr). \quad (6.2)$$

Let us justify our claim. With probability 1, there exists a finite (random) $\varepsilon$ such that displacement of the locations $x_i$ with $(x_i, r_i) \in \phi|_{B_n(2b)}$ by at most $\varepsilon$, and modification of the corresponding $r_i$ by at most $\varepsilon$, would not affect the intersection graph on $B_n \cup B_r(x)$. Suppose $\phi$ is such that there are disjoint paths $P, P'$ in configuration $\phi + \delta(x,r)$, with $P$ joining $B_r(x)$ and $\mathbb{R}^d \setminus B_n$ and $P'$ joining $L$ and $\mathbb{R}^d \setminus B_n$ and using $B_r(x)$, and suppose

Figure 1: Geometry of the paths (depicted as black curves) connecting $L$ to $\mathbb{R}^d \setminus B_n$. Pivotal grains for $J^n_L$ are coloured white. The last pivotal grain starting from $L$ is denoted $K$. 

20
also all paths joining \( L \) to \( \mathbb{R}^d \setminus B_n \) use \( B_r(x) \). Let \( \varepsilon \) be as defined above. Let \( \mathcal{K} \) be a union of rational \((d + 1)\)-cubes of side less than \( \varepsilon/(d + 1) \) centered on the points \((x_i, r_i)\) such that \( B_{r_i}(x_i) \in P \). Let \( \mathcal{L} \) be the complement of \( \mathcal{K} \) in \( \mathbb{R}_d \times \mathbb{R}_+ \).

If we modify our configuration \( \Phi \) arbitrarily in \( \mathcal{L} \) then we are still in \( J_{B_r(x)}^n \), since the points of \( \Phi \) inside \( \mathcal{K} \) guarantee occurrence of \( J_{B_r(x)}^n \).

On the other hand, if we modify \( \Phi \) arbitrarily in \( \mathcal{K} \) then we still have a path joining \( L \) to \( \mathbb{R}^d \setminus B_n \) using \( B_r(x) \) (because our configuration in \( \mathcal{L} \) contains such a path) but every such path uses \( B_{r_i}(x) \) (because in \( \Phi \) our path \( P \) did not intersect with any path joining \( L \) to \( B_r(x) \), and hence, by the choice of \( \varepsilon \), neither does any modification of \( P \) by moving points a distance at most \( \varepsilon/(d + 1) \) in each coordinate, and the rest of \( \Phi \) is unchanged).

Note that our regions \( \mathcal{K}, \mathcal{L} \) are unions of rational rectangles in \((d + 1)\)-space, not in \( d \)-space as in Gupta and Rao (1999). To see that Gupta and Rao (1999) is applicable, note that we can generate our Poisson process \( \Phi = \sum_i \delta(x_i, r_i) \) in \( \mathbb{R}^d \times \mathbb{R}_+ \) from a homogeneous point process \( \sum_i \delta_{y_i} \) of intensity \( t \), where for the last line we have used Theorem 3.2 and the monotonicity of \( \theta \).

Next we bound \( \theta_L(t) \) from below. Pick \( x \in L \). If \( B_b(x) \cap Z_{\infty}(\Phi) \neq \emptyset \) and also \( B_b(x) \subset Z(\Phi) \), then \( L \cap Z_{\infty}(\Phi) \neq \emptyset \). Hence by the Harris-FKG inequality for Poisson processes (see, e.g. Last and Penrose (2016, Ch.20)), and translation-invariance, we have for \( t \geq t_c \) that

\[
\theta_L(t) \geq \theta_{B_b(x)}(t) \mathbb{P}_{tF} \{ B_b(x) \subset Z \} = \theta_{B_b(x)}(t) \mathbb{P}_{tF} \{ B_b \subset Z \}. \tag{6.4}
\]
Setting $\alpha = \mathbb{P}_{t,F}\{B_b \subset Z\}$ and substituting (6.4) into (6.3), we get to
\[
\theta'_L(t) \geq \frac{(1 - \theta_L(t))\theta_L(t)}{t \theta_{B_b}(t)} \geq \frac{\alpha(1 - \theta_L(t))}{t}.
\]

Integrating over $t$, using the continuity of $\theta'_L(\cdot)$ on $(t_c, \infty)$ and the monotonicity of $\theta_L(\cdot)$, we therefore have that
\[
\theta_L(t) - \theta_L(t_c) \geq \alpha(t - t_c) \frac{1 - \theta_L(t)}{t},
\]
which is (3.6). Since $\theta_L(t)$ is continuous from the right, $\theta_L(t) = \theta_L(t_c) + o(1)$ as $t \downarrow t_c$, giving (3.7).

\section{Final remarks}

In this paper we have studied the capacity functional of the infinite cluster of a spherical Boolean model. Our main results (Theorems 3.2 and 3.4) require the radii to be deterministically bounded. It can be expected that these results also hold for more general Boolean models with connected grains having a deterministically bounded circumradius. It can also be conjectured that good moment properties of the circumradius should suffice to imply the result for unbounded radii. The proof of this latter extension, however, does not seem to be straightforward.

The methods of this paper can probably be used to derive differentiability properties of the expectations of other functionals of the Boolean model. A whole family of such functionals in the subcritical regime can be defined in terms of the number of the expectations of other functionals of the Boolean model. A natural step after the infinite differentiability would be to show that the capacity is an analytic function of intensity in the supercritical phase. It might be possible to use (3.3) to show that for fixed supercritical $t$, the Taylor series for $\theta_L((t + h)F)$ as a function of $h$ has positive radius of convergence; however this seems to need tighter bounds than those used here, and hence, new ideas.

Also of interest is the \textit{n-point connectivity function} of the Boolean model. Given $x_1, \ldots, x_n \in \mathbb{R}^d$, and given $F \in \text{M}_1^d$, for $t > 0$ let $\tau_{x_1, \ldots, x_n}(t)$ denote the $\mathbb{P}_{t,F}$-probability that the points $x_1, \ldots, x_n$ all lie in the same component of $Z(\Phi)$. It is not hard to prove that $\tau_{x_1, \ldots, x_n}(t)$ is continuous in $t$ (see, e.g., [Jiang et al. (2011)]). Using the method of proof of Theorem 3.1 it should be possible to show further that $\tau_{x_1, \ldots, x_n}(t)$ is infinitely differentiable in $t$ on the interval $(t_c(F), \infty)$. Moreover, the $n$-point connectivity function of $Z_\infty(\Phi)$ (as opposed to that of $Z(\Phi)$) is certainly infinitely differentiable, since by the inclusion-exclusion formula the probability $\mathbb{P}_{t,F}(\cap_{i=1}^n \{x_i \in Z_\infty(\Phi)\})$ can be expressed as a linear combination of the capacity functionals of the subsets of the families of $\{x_1, \ldots, x_n\}$, plus a constant.

It may be possible to generalize Theorem 3.4 as follows. Let $F_0 \in \text{M}_1^d$ and $F \in \text{M}_1^d$. Let $t_c(F_0, F)$ be the supremum of those $t$ such that $\theta(F_0 + tF) = 0$ and assume $F_0, F$
are such that $t_c(F_0, F) > 0$. Then we might expect that similar results to (3.6) and (3.7) would hold with $tF$ replaced by $F_0 + tF$ (and $t_c F$ replaced by $F_0 + t_c F$ and $t_1 F$ replaced by $F_0 + t_1 F$ wherever they appear.

We have shown that $\theta_L$ is (under the assumptions of Theorem 3.2) infinitely differentiable on $(t_c, \infty)$. It would be extremely interesting to understand the behaviour of the second derivative near the critical value. We leave this as a challenging problem for future research.

Acknowledgment. The mistake in the original paper [Last et al. (2017)] was originally brought to our attention by Emil Schmitz, to whom we are indebted for pointing this out to us.
