Interleukin-12 (IL-12) is a heterodimeric cytokine composed of a p35 subunit specific to IL-12 and a p40 subunit shared with IL-23. In this study, we unveiled the existence of two p35 paralogues in grass carp (named gcp35a and gcp35b). Notably, gcp35a and gcp35b displayed distinct inducible expression patterns, as poly I:C merely induced the gene expression of gcp35a but not gcp35b, while recombinant grass carp interferon-gamma (rgcIfn-γ) only enhanced the transcription of gcp35b but not gcp35a. Moreover, the signaling mechanisms responsible for the inducible expression of gcp35a and gcp35b mRNA were elucidated. Because of the existence of three grass carp p40 genes (gcp40a, gcp40b and gcp40c) and two p35 paralogues, six gcIl-12 isoforms were predicted by 3D modeling. Results showed that gcp40a and gcp40b but not gcp40c had the potential for forming heterodimers with both gcp35 paralogues via the disulfide bonds. Non-reducing electrophoresis experiments further disclosed that only gcp40b but not gcp40a or gcp40c could form heterodimers with gcp35 to produce secretory heterodimeric gcp35a/gcp40b (gcIl-12AB) and gcp35b/gcp40b (gcIl-12BB), which prompted us to prepare their recombinant proteins. These two recombinant proteins exhibited their extensive regulation on Ifn-γ production in various immune cells. Intriguingly, both gcIl-12 isoforms significantly enhanced the transcription of il-17a/f1 and il-22 in lymphocytes, and their regulation on il-17a/f1 expression was mediated by Stat3/Rorγt signaling, supporting the potential of gcIl-12 isoforms for inducing Th17-like responses. Additionally, stimulatory effects of gcIl-12 isoforms on il-17a/f1 and ifn-γ expression were attenuated by gcTgf-β1 via suppressing the activation of Stat3 signaling, implying that their signaling could be manipulated. In brief, our works provide new insights into the inducible expression pattern, heterodimeric generation and functional novelty of Il-12 isoforms in teleosts.

Keywords: grass carp, IL-12, p35 paralogues, heterodimeric form, Th17-like response
INTRODUCTION

Interleukin-12 (IL-12) is a heterodimeric cytokine composed of two subunits, p35 and p40 covalently bound through an inter-chain disulfide bond (1). The co-expression of two subunits in the same cells is vital to the formation of IL-12, although the expression of each subunit is differently regulated (2). Since p35 subunit is specific to IL-12 and p40 subunit is shared with IL-23 (3), the production of IL-12 heterodimer is limited by p35 expression (4). In mammals, IL-12 acts on the target cells by binding to heterodimer receptors IL-12Rβ1 and IL-12Rβ2 (5), and activates the tyrosine kinase 2 (TYK2) and Janus kinase 2 (JAK2), respectively (6). Activation of JAK2 predominantly results in signal transducer and activator of transcription 4 (STAT4) phosphorylation and ultimately leads to interferon-gamma (IFN-γ) production (7) as well as Th1 cell differentiation (8). Besides STAT4, STAT3 also participates in the regulation of IL-12 on Th1 differentiation (9).

Unlike in mammals, multiple p35 and p40 paralogues have arisen in teleosts due to the teleost-specific whole-genome duplication (WGD) events (10). In various fish species, p35 paralogue gene expressions are induced by poly I:C, LPS, IL-6, IL-1β, Ifn-γ (11), Nocardia seriolae (12), and Yersinia ruckeri (13). While p40 paralogue transcriptions are stimulated by immune stimuli like IL-1β, Tnf-α3 (11), viral hemorrhagic septicaemia virus (VHSV) and Yersinia ruckeri (14). However, the exact mechanisms governing the transcription of these fish p35 paralogues remain unclear. Notably, the existence of multiple p35 and p40 paralogues may lead to multiple IL-12 isoforms in fish. Accordingly, recombinant IL-12 isoforms of two teleosts, amberjack (12) and rainbow trout (14) have been prepared, and recombinant proteins had classical regulatory effects on the expression of Ifn-γ. It is noteworthy that rainbow trout IL-12 isoforms possess distinct activities in the induction of IL-10 gene expression (14). However, the roles of these distinct p35 and p40 paralogues in generating IL-12 isoforms are unknown, and at least two issues are needed to be addressed in fish species: Firstly, whether the inducible expression of p35 paralogues is stimuli-specific; Secondly, whether all heterodimer combinations of p35 and p40 paralogues exist.

In this study, we isolated and identified a new p35 gene in grass carp, which was named gcp35b differing from the gcp35a reported previously (15). Subsequently, immune-stimulated expression profiles of two gcp35 paralogues and the related signaling mechanisms were examined in grass carp monocytes/macrophages, providing information on the specific expression patterns of two gcp35 paralogues. It is known that there are three grass carp p40 genes (gcp40a, gcp40b and gcp40c) (16), raising a question about how many IL-12 isoforms exist in grass carp. Along this line, the six predicted gcll-12 heterodimers were constructed by 3D modeling and the existence of secretory gcll-12 isoforms was identified by non-reducing electrophoresis, supporting that only two heterodimeric IL-12 isoforms were presented in grass carp. To better understand the function of two gcll-12 isoforms, their recombinant proteins were prepared and their potentials to stimulate Ifn-γ production were confirmed in various immune cells. Unexpectedly, the gcll-12 isoforms exhibited the ability to function as novel regulators of Th17-like response in grass carp lymphocytes. Finally, inhibitory effects of Tgf-β1 on gcll-12 isoform signaling were elucidated in the same cell model.

MATERIALS AND METHODS

Animal and Reagents

Healthy grass carp weighing about 0.75-1.00 kg was obtained from Chengdu Tongwei Aquatic Science and Technology Company (Chengdu, China). After an adaptation period of 7 days, the fish was anesthetized in 0.05% MS222 (Sigma-Aldrich, MO, USA) and sacrificed. The head kidney was taken from the fish for head-kidney leukocytes (HKLs), lymphocytes and monocytes/macrophages isolation. All animal experiments were reviewed and conducted according to the Regulation of Animal Use in Sichuan province, China, and were approved by the ethics committee of the University of Electronic Science and Technology of China.

The recombinant gcIfn-γ (rgcIfn-γ, 500 ng/mL) (17), rgcTgf-β1 (100 ng/mL) and anti-gcTgf-β1 mAb (1:2000 diluted) were prepared referring to our previous studies (18, 19). LPS from Escherichia coli O55:B5 and poly I:C were purchased from Sigma Aldrich, and their doses used in this study were determined according to our previous studies (17, 18, 20, 21). Inhibitors for NF-κB (PDTC, 0.25 µM, Sigma Aldrich, St. Louis, USA), ERK1/2 (PD98059, 30 µM, Merck, Bad Soden, Germany), JNK (SP600125, 6 µM, Merck), P38 (SB202190, 30 µM, Merck), activin receptor-like kinase 5 (ALK5, TGF-β1 RI Kinase inhibitor VIII, 2 µM, Calbiochem, EMD Chemicals, San Diego, USA), RORγt (SR1001, 15 µM, Sigma-Aldrich) and STAT3 (STAT3 VI, 30 µM, Sigma-Aldrich) were used and an equal amount of solvent was used in the control groups in the experiments. The use of these inhibitors referred to previous studies (18, 22–25). Among them, anti-gcTgf-β1 mAb and ALK5 inhibitor were used to confirm the role of Tgf-β1 signaling in limiting rgc12BB actions.

Molecular Cloning of gcp35b cDNA and Sequence Analysis of p35 Homologues

Total RNA was extracted from the grass carp head kidney with TRIzol Isolation Reagent (Roche, Basel, Switzerland) and then reverse transcribed to cDNA by using M-MLV reverse transcriptase (Promega, Madison, USA) with oligo d(T)18 as the primer. The potential sequence encoding gcp35b was obtained by searching the grass carp genome sequence (http://www.ncbi.nlm.nih.gov/nextgrasscarp/) with the offline BLAST tool based on the sequence of zebrafish p35b (GenBank ID: XM_017352586). The full-length gcp35b cDNA sequence was amplified from the grass carp head kidney cDNA by Phusion High-Fidelity DNA Polymerase (Vazyme, Nanjing, China) and sequenced. The cDNA and deduced amino acid sequence of gcp35b were analyzed by using the ExPASy Molecular Biology server.
The molecular weight and isoelectric point of the putative gcp35b were predicted by Compute PI/Mw tool (http://web.expasy.org/compute_pi/) and the deduced signal peptide was predicted using SignalP (http://www.cbs.dtu.dk/services/SignalP/). The potential N-glycosylation sites of grass carp Il-12 subunits were predicted by NetNGlyc 1.0 Server (http://www.cbs.dtu.dk/services/NetNGlyc/). Gene synteny of the p35 loci was analyzed using the data from the NCBI database (https://www.ncbi.nlm.nih.gov/). The multiple amino acid alignments and the phylogenetic tree were constructed by MEGA7.1 software (https://www.megasoftware.net/)

Structural Modeling of Grass Carp Il-12 Heterodimer

The structural models of grass carp Il-12 heterodimer were constructed by SWISS-MODEL (http://swissmodel.expasy.org) based on the human Il-12 crystal structure (PDB:1F45). The molecular graphics visualization tool RasMol 2.7.2.1 (http://www.openrasmol.org/) was used to display the structural models. These predicted models were evaluated by the Qualitative Mean Energy Analysis Distance Constraint Global (QMEANDis Co Global) of SWISS-MODEL (https://swissmodel.expasy.org/qmean/)

Plasmid Construction

To study the existence of gcIl-12 isoforms, the coding sequences (CDS) of grass carp p35a and p35b were amplified by Phusion High-Fidelity DNA Polymerase (Vazyme) with the primers listed in Supplementary Table 1. The CDS of gcp35a and gcp35b were separately subcloned into p3×FLAG-CMV-7.1 (Promega) to obtain the N-terminal FLAG-tagged gcp35a (gcp35a-FLAG) and gcp35b (gcp35b-FLAG) plasmids. The C-terminal HIS-tagged gcp40a/b/c (gcp40a/b/c-HIS) expression plasmids have been used in our previous study in which gcp19 and gcp40a/b/c heterodimeric assembly is investigated (16). The integrity of the inserted DNA fragments was verified by sequencing. The highly purified and endotoxin-free DNA plasmids were extracted from Escherichia coli (E. coli) by using a TIAN prep Mini Plasmid Kit (Tiangen, Beijing, China) for subsequent transfection. The HEK293 cells (2 × 10⁴ cells/35 mm culture dish) were transiently transfected with different combinations of gcp35a/b-FLAG and gcp40a/b/c-HIS plasmids (1.2 µg of each plasmid/35 mm culture dish) by using Lipofectamine 2000 Reagent (Thermo Scientific, Carlsbad, USA), separately. Forty-eight hours after transfection, the cell culture supernatants were collected and examined by a non-reducing Western Blotting (WB) assay.

Recombinant Expression and Purification of gcIl-12 Isoforms

To acquire the recombinant gcIl-12 isoforms, a (GGGGS)₃ linker was used to link the p35 subunit and p40 subunit (p40-(GGGGS)₃-p35). Briefly, the cDNA sequences encoding mature gcp35a/b were amplified by primers of p35a/b-HindIII G4S3 linker F, p35a-‐C-myc+6'his TGA XhoI R and p35b-XhoI R (Supplementary Table 1) with Phusion High-Fidelity DNA Polymerase (Vazyme) and then cloned into dhfr-deficient CHO (CHO-dhfr⁻/) cell expression vector pSV2-dhfr (Youbio, Changsha, China) after digested with HindIII and XhoI (NEB). Next, the DNA fragment encoding the gcp40b was amplified by PCR using the primers with HindIII restriction site (Supplementary Table 1) and subsequently inserted into the expression vector containing gcp35a or gcp35b after the digestion with HindIII. The integrity of the inserted DNA fragments was verified by sequencing. Then the highly purified and endotoxin-free DNA plasmids were extracted from E. coli by using a TIAN prep Mini Plasmid Kit (Tiangen).

CHO cells were seeded at a density of 2 × 10⁴ cells/35 mm culture dish in IMDM medium (Gibco, NY, USA) supplemented with 10% FBS (Gibco), 1% HT (Gibco) and 1% antibiotic-antimycotic (Thermo Scientific) for 24 h before transfection. The plasmids for two gcIl-12 isoforms were separately transfected into the CHO cells by Lipofectamine 2000 according to the manufacturer’s instructions (Thermo Scientific). Forty-eight hours after transfection, cells were selected in the IMDM medium with 10% FBS (Gibco) and 1% antibiotic-antimycotic (Thermo Scientific) which contains different concentrations of methotrexate (MTX) (Life Technologies, Gaithersburg, MD). MTX is commonly used as a selective antibiotic in the dihydrofolate reductase (dhfr) selection system. After cultured in high dose of MTX (500 nM), the transformed clones were isolated using 10 µL pipette tips and screened by WB assay. The selected clones were cultured in 5 mL SFM4CHO medium (Gibco) in 50 mL BD tubes at 37°C with shaking at 180 rpm for 48 h and then those cells were transferred to a 125 mL flask and cultured with 30 mL SFM4CHO medium at 32°C with shaking at 180 rpm for a week. The gcIl-12 isoforms in the culture medium were purified by His Trap affinity column (GE Healthcare, Waukesha, USA) and desalted by the Superdex-G25 prep grade column (GE Healthcare). The molecular weight and purity of purified proteins were analyzed on SDS-PAGE and WB. Finally, the gcIl-12 isoforms were lyophilized and then stored at ~80°C for further use.

SDS-PAGE and WB Assay

The non-reducing electrophoresis with SDS but without β-mercaptoethanol (β-ME) was used to determine the gcIl-12 heterodimer composition. In this scenario, the cell culture media of HEK293 cells transfected with gcp35a/b and gcp40a/b/c expression plasmids were harvested at 48 h after transfection and added a 5×loading buffer without β-ME, and then the samples were boiled at 70°C for 10 min. After that, these samples were separated on 10% SDS-PAGE, and then electrophoretically transferred to a PVDF membrane (Millipore, Billerica, MA). The membrane was blocked by TBST buffer (1% Tween) containing 10% (wt/vol) defatted dry milk for 2 h at room temperature and then incubated with anti-HIS mAb (1:600, ZSGB-BIO, Beijing, China) or anti-FLAG mAb (1:5000, Cell Signaling Technology, MA, USA) overnight at 4°C. The membrane was exposed to horseradish peroxidase (HRP)-conjugated goat anti-rabbit secondary antibody (1:5000, ZSGB-BIO) for 2 h at room temperature. Finally, signals were detected
using an ECL kit (Roche Diagnostics, Mannheim, Germany) according to the manufacturer’s instructions.

To detect the activation of signaling pathways, the cell lysates were separated on 12% SDS-PAGE and the signaling molecules were detected by WB assay using specific primary antibodies for phosphorylated ERK (anti-pERK1/2, 1:1000, Cell Signaling Technology), JNK (anti-pJNK, 1:1000, Cell Signaling Technology), p38 (anti-p-p38, 1:1000, Cell Signaling Technology), IκBα (anti-p-IκBa, 1:1000, Cell Signaling Technology), STAT3 (anti-pSTAT3, 1:1000, Anaspec, Fremont, CA, USA), and the β-actin (anti-β-actin 1:5000, Boster, Wuhan, China) as the loading control. These antibodies detecting the activated state of signaling molecules are raised against peptides based on the phosphorylation sites of each signaling molecule (Figure S5B), and they have been applied and effectively recognized the corresponding molecules in grass carp and other fish species (23, 26–28). The predicted sizes and amino acid sequence alignment analysis of these signaling molecules in grass carp are shown in Figure S5.

The molecular weight and purity of two rgcIl-12 isoforms were evaluated by SDS-PAGE and verified by Western blotting using anti-gcIfn-γ pAb (1:1000), anti-gcIFN-γ pAb (1:1000) and anti-gcP40b pAb (1:1000), Biogot Technology, Nanjing, China). In the experiments, anti-gcIfn-γ pAb and anti-gcIFN-γ pAb were custom products from Abmart Inc. (Shanghai, China). To validate anti-gcIfn-γ pAb specificity, the recombinant gcIfn-γ and grass carp HKLs lysates were analyzed by WB in which the membrane was incubated with anti-gcIfn-γ pAb (1:1000) or the antibody pre-absorbed with rgcIfn-γ (Figures S6A, B). Following the same procedures, the lysates of grass carp HKLs treated with or without heat-killed Aeromonas hydrophila (A. hydrophila) (MOI 1:1, which has been described previously (29)) for 6 h were used to verify the specificity of the gcP35a antibody (Figures S6C, D). Additionally, the specificity of anti-gcP40b pAb has been demonstrated and used in previous research (30).

Isolation and Culture of Grass Carp HKLs, Lymphocytes and Monocytes/ Macrophages

Grass carp HKLs were prepared by discontinuous density gradient centrifugation with Ficoll-Hypaque (1.083 kg/L, TBD science, Tianjin, China) referring to our previous studies (23). Briefly, head kidney was obtained from freshly sacrificed fish and then squeezed to release the cells. After the tissue debris was removed, the cells were layered on Ficoll-Hypaque and centrifuged at 1580 × g for 30 min at 20°C. After centrifugation, the leukocytes at the interface were collected and washed twice with PBS. The cells were resuspended in RPMI-1640 medium (Gibco) with 10% FBS (Gibco) and 1% antibiotic-antimycotic (Thermo Scientific) and washed twice with PBS. The cells were resuspended in RPMI-1640 medium (Gibco) with 10% FBS (Gibco) and 1% antibiotic-antimycotic (Thermo Scientific) and seeded in a 24-well plate with 5 × 10⁶ cells/well. After 2 hours of incubation, the unattached cells on the plate were washed away with PBS. Then the cells were cultured in RPMI-1640 medium (Gibco) with 10% FBS (Gibco) and 1% antibiotic-antimycotic (Thermo Scientific). In the following day, the cells were treated with different drugs in individual experiments.

Gene Expression Analysis by Real-Time Quantitative PCR (RT-qPCR)

Total RNA was extracted from the cells and then reverse transcribed to cDNA by using M-MLV reverse transcriptase (Promega). The gcp35a, gcp35b, il-17a/f1, il-22 and β-actin mRNA levels were assessed by using RT-qPCR. In brief, RT-qPCR was performed on the Bio-Rad CFX96™ Real-time detection system (Bio-Rad, Hercules, CA) in a total volume of 10 µL with 4 µL of 2.5 × RealMasterMix (Tiangen, Beijing, China), 0.5 µL of 20 × SYBR Green, 1 µL of cDNA, 0.2 µL of each of forward primer and reverse primer and 4.1 µL of deionized water. The amplification program was 94°C for 2 min, followed by 35 cycles of 94°C for 20 s, 54-60°C (54°C for p35a, 60°C for p35b, 60°C for il-17a, 60°C for il-17a/f1, 60°C for il-22 and 59°C for β-actin) for 20 s and 65°C for 20 s. All PCR products were visualized on a 2% agarose gel to check the PCR amplification. To estimate the amplification efficiency, the standard curve for each target molecule was generated by 10-fold serial dilutions (from 10⁻¹ to 10⁶ fmol/µL) of a plasmid containing the individual target gene sequences as the PCR template. The melting analysis was routinely performed to check the authenticity of the PCR products (31). The relative expression levels of target genes were analyzed using the 2⁻ΔΔCt method (32) by normalization with β-actin gene expression and presented as fold changes compared with the matched controls. The primers for the RT-qPCR are listed in Supplementary Table 1.

Competitive-Inhibition Enzyme Linked Immunosorbent Assay (ELISA)

The grass carp HKLs culture medium was collected to measure the concentration of grass carp Ifn-γ by competitive-inhibition ELISA. In the assay, anti-gcIfn-γ pAb was a custom product from Abmart (Shanghai, China). To validate anti-gcIfn-γ pAb specificity, the recombinant gcIfn-γ (rgcIfn-γ) was used and analyzed by SDS-PAGE (Figure S10A) and WB in which the membrane was incubated with anti-gcIfn-γ pAb (1:1000) (Figure S10B) or the antibody pre-absorbed with rgcIfn-γ (Figure S10C). To establish a competitive-inhibition ELISA, an orthogonal experiment was designed by setting different coating concentrations of gcIfn-γ, and the dilution ratios of primary antibody and secondary antibody. The optimized
amount of coating antigen was 100 ng/well of rgcIfn-γ and concentrations of the antibodies were 1:1000 (v/v) of anti-gcIfn-γ pAb (1:1000) and HRP-conjugated goat anti-rabbit secondary antibody. Subsequently, a standard curve was built according to the inhibition ratio and the corresponding protein concentrations (Figure S11).

In this experiment, a 96-well polystyrene plate (Costar, Cambridge, MA, USA) was coated with 100 ng/well of rgcIfn-γ at 4°C for 16 h and then blocked with 5% defatted milk plus 0.3% BSA in PBS for 3 h at room temperature. At the same time, 50 µL of culture medium or the titrated rgcIfn-γ and 50 µL of anti-gcIfn-γ pAb (1:1000) (Abmart) were mixed and incubated at room temperature for 2 h. After that, the plate was washed with PBST (0.05% Tween-20 in PBS) for three times and 100 µL of the medium-antibody mixture was added into each well and further incubated at room temperature for 2 h. The plate was washed with PBST for five times, and then 100 µL of HRP-conjugated goat anti-rabbit secondary antibody (1:1000, ZSGB-BIO) was added into each well. After 2 h incubation at room temperature, the plate was washed with PBST for five times and 100 µL of substrate buffer (TMD, Tiangen) was added into the wells and incubated for 20 min at 37°C. The reaction was stopped by 2 M H2SO4 and the absorbance values were measured at 450 nm with the iMark Microplate Reader (Bio-Rad). Control groups were pre-coated with BSA followed by the same procedures as described above. The concentrations of samples were extrapolated from a standard curve for gcIfn-γ inhibition.

**Results**

**Molecular Cloning of gcp35b and Sequence Analysis of p35 Homologues**

Although two or three p35 paralogues were found in a variety of teleosts, only one p35 gene has been reported so far in grass carp (nominated as gcp35a in the present study). In this study, another grass carp p35 cDNA (named gcp35b) was isolated, which contains 582 bp nucleotides encoding a 193-aa polypeptide (Figure S1). Moreover, gcp35b loci exhibited a conserved synteny with its homologues in other teleost species like fugu, Atlantic salmon and zebrafish, and both gcp35 paralogues were in proximity with the conserved gene schip1 (Figure 1A). Subsequent phylogenetic analysis of p35 showed three sub-clades: teleost p35a, p35b branches, and the branch consisted of frog, chicken and mouse p35 genes (Figure 1B). The multiple amino acid sequences alignment of gcp35b with its homologues showed that it had the highest identity with zebrafish p35b (50.93%) and shared low identities with other homologues in teleosts (fugu p35a 17.47%, fugu p35b 19.70%, zebrafish p35a 18.22% and grass carp p35a 20.07%). In addition, gcp35b also shared lower identities (14.87%, 12.64%, 14.50% and 13.01%) with the human, mouse, chicken and frog p35 homologues (Figure S2A). Furthermore, the cysteine residues (C28, C60, C77, C87, C100, C138 and C168 of gcp35a, C41, C67, C84, C91, C104, C142 and C170 of gcp35b) were conserved with p35 homologues in other vertebrate species (Figure S2A). The cysteine residues (C37 of gcp35a and C91 of gcp35b) that form the inter-chain disulfide bond were marked with a star (Figure S2A). The glycosylation sites of gcp35a/b were highlighted in Figure S3.

**Glycosylation Analysis of rgcII-12AB and rgcII-12BB**

To examine if the rgcII-12AB and rgcII-12BB expressed by CHO cells were glycosylated, PNGase F (NEB), a glycosidase, was used to digest rgcII-12AB and rgcII-12BB following the manufacturer’s instructions. According to the method in a previous study (33), 10 µg of rgcII-12AB or rgcII-12BB was denatured in 1 × Glycoprotein Denaturing buffer (0.5% SDS, 40 mM DTT) for 10 min in boiling water, and added to 10 × G2 Reaction buffer (500 mM PBS, pH 7.5) containing 2 µL of 10% NP-40 and 2 µL of PNGase F. The mixture was incubated at 37°C for 2 h and the samples were assayed by SDS-PAGE and WB.

**Data Interpretation and Statistical Analysis**

Data were collected from at least three independent experiments and all results were expressed as mean ± SEM with four independent replicates (N = 4). GraphPad Prism 7 software (GraphPad Inc., San Diego, CA, USA) was used to test the normality and homogeneity of variance of all data according to the instructions of GraphPad Prism (https://www.graphpad-prism.com/guides/prism/8/statistics/index.htm), and then perform statistical analyses. For comparison between two groups, Student’s t-test was performed. Multiple group comparison was conducted by one-way ANOVA followed by a Tukey’s multiple comparisons test. Significant differences and highly significant differences were considered at p < 0.05 and p < 0.01, respectively.
30 min (Figure 2E). Referring to the information available at Cell Signaling Technology’s website (https://www.cellsignal.com/), the molecular sizes of p-JNK, p-ERK1/2, p-IκBα and p-p38 in grass carp were similar to that in mammals (Figure S5A).

3D Structural Models of Heterodimers Consisted With gcp35 and gcp40 Paralogues

To learn the structural information of theoretical gcIl-12 heterodimers, their 3D models were constructed based on the human IL-12 crystal structure (PDB: 1F45), thereby revealing the location of those conserved cysteine residues on the contact surface of the predicted heterodimers consisting of gcp35 and gcp40 paralogues (Figure 3). The QMEANDisCo Global scores of all gcIl-12 heterodimer 3D models were higher than 0.5 (Supplementary Table 2). As shown in Figure 3, the conserved cysteine residues on the contact surfaces of the predicted heterodimers included gcp35a (C87) and gcp35b (C91) marked by black arrows, as well as C184 and C300 of gcp40a and the C176 and C237 of gcp40b indicated by red arrows. However, no cysteine residue was found on the contact surface of gcp40c.

Selective Generation of gcIl-12 Isoforms in HEK293 Cells

To clarify the composition of the gcIl-12 heterodimer, different combinations of gcp35a/b-FLAG and gcp40a/b/c-HIS were overexpressed in HEK293 cells, and then the cell culture media were collected and analyzed under non-reducing conditions. As shown in Figure 4, anti-FLAG antibody and anti-HIS antibody could detect the monomeric gcp35a (35 kDa) and gcp35b (35 kDa) marked by black arrows, as well as C184 and C300 of gcp40a and the C176 and C237 of gcp40b indicated by red arrows. However, no cysteine residue was found on the contact surface of gcp40c.
anti-FLAG antibody recognized an obvious band with the MW of 75 kDa in overexpressing gcp35a/gcp40b and gcp35b/gcp40b lanes (indicated by “heterodimer”, Figure 4A). Consistently, this band was also detected by anti-HIS antibody in the same lanes (indicated by “heterodimer”, Figure 4B). In addition, homodimeric gcp35b (50 kDa) was detected by anti-FLAG antibody (right panel, Figure 4A). Similarly, homodimeric gcp40a (more than 100 kDa) was detected by anti-HIS antibody (Figure 4B).

**Recombinant Expression and Purification of gcIl-12 Isoforms**

To explore the biological activity of two main gcIl-12 isoforms as described above, the recombinant gcIl-12AB (rgcIl-12AB) and gcIl-12BB (rgcIl-12BB) were prepared by the CHO cell expression system and purified by His Trap affinity column, and their purity was evaluated by SDS-PAGE and WB. SDS-PAGE analysis showed that the purified gcIl-12AB (Figure S7A) and gcIl-12BB (Figure S7D) were visualized as a single band about 75 kDa and 70 kDa, respectively, and they were larger than their predicted MW (rgcIl-12AB with 58 kDa and rgcIl-12BB with 57 kDa). Furthermore, the single band of purified gcIl-12AB was verified by WB analysis with anti-gcp35a and anti-gcp40b pAb (Figures S7B, C), while a single band for rgcIl-12BB was recognized by both anti-gcp35b and anti-gcp40b pAb (Figures S7E, F). The glycosylation of rgcIl-12AB and rgcIl-12BB was assessed by glycosidase digestion. SDS-PAGE analysis showed the MWs of gcIl-12AB and gcIl-12BB digested with glycosidase were corresponding to their predicted sizes, respectively (Figures S8A, B) and these results were further confirmed by WB assay (Figures S8C, D).

**Functional Verification of gcIl-12 Isoforms in Grass Carp HKLs, Lymphocytes and Monocytes/Macrophages**

To investigate the biological activity of two gcIl-12 isoforms, grass carp HKLs were incubated with different concentrations of gcIL-12AB or gcIL-12BB for 12 h. Results showed that gcIL-12AB (Figure 5A) and gcIL-12BB (Figure 5B) could induce Ifn-γ mRNA expression from 30 to 1000 ng/mL. In parallel, a time course experiment showed that a 12-h treatment of gcIL-12BB (1000 ng/mL) was sufficient to induce the maximal effect on Ifn-γ expression in HKLs (Figure S9). Furthermore, the competitive-inhibition ELISA results showed that gcIL-12AB (100-1000 ng/mL) and gcIL-12BB (100-1000 ng/mL) markedly stimulated the release of Ifn-γ (Figures 5C, D). Similarly, in lymphocytes and
FIGURE 3 | 3D structural models of grass carp IL-12 isoforms. The structural models of grass carp IL-12 isoforms were constructed based on the human IL-12 crystal structure (PDB: 1F45). The exposed cysteines at the contact surface of gcp35 paralogues are marked with black arrows and the red arrows indicated the cysteines of gcp40 paralogues.

FIGURE 4 | Identification of the grass carp IL-12 heterodimer composition. HEK293 cells were transfected with 1.2 µg of plasmids encoding the individual subunits alone or with a mixture of 1.2 µg of each of the two plasmids as indicated in picture. The cell culture media samples were separated under non-reducing conditions (without β-ME). The molecular mass standards (kDa) are indicated. The lane of ctrl means that HEK293 cells were transfected with a mixture of 1.2 µg each of the two vectors (p3×FLAG-CMV-7.1 and pcDNA 3.1/myc-His (-)). (A) Non-reducing WB assay by using anti-FLAG antibody. (B) Non-reducing WB assay by using anti-HIS antibody.
monocytes/macrophages, a 12-h treatment with rgcIl-12AB or rgcIl-12BB (30-1000 ng/mL) resulted in the increase of ifn-γ transcription (Figures 6A–D).

**Effects of rgcIl-12 Isoforms on the mRNA Expression of Th17 Related Cytokines in Grass Carp Lymphocytes and Monocytes/Macrophages**

In lymphocytes, both rgcIl-12AB and rgcIl-12BB were effective in enhancing the Th17 related cytokines il-17a/f1 and il-22 mRNA expression from 30 to 1000 ng/mL (Figures 7A–D). At the same time, in monocytes/macrophages, the different concentrations (30-1000 ng/mL) of rgcIl-12AB and rgcIl-12BB had no effect on the expression of il-17a/f1 and il-22 (Figures S12A–D).

**Signaling Transduction Mechanisms for gcIl-12 Isoforms-Stimulated Il-17a/f1 Transcription in Grass Carp Lymphocytes**

To elucidate the signaling mechanisms in the modulation of gcIl-12 isoforms on il-17a/f1 transcription, the inhibitors for Stat3 and Rorγ signaling were used in the present study. Results showed that the stimulatory effects of gcIl-12AB and gcIl-12BB (1000 ng/mL) on the il-17a/f1 mRNA expression were impeded by STAT3 VI (30 µM, STAT3 inhibitor) (Figures 8A, D) and SR1001 (15 µM, RORγt inhibitor) (Figures 8B, E). In addition, gcIl-12AB (1000 ng/mL) was able to induce the phosphorylation of Stat3 from 5 to 20 min (Figure 8C) and gcIl-12BB (1000 ng/mL) was able to induce the phosphorylation of Stat3 from 5 to 60 min (Figure 8F).
Modification of gcTgf-β1 on the Regulatory Effects of gcIl-12 Isoforms in Grass Carp Lymphocytes

To assess whether the regulatory effects of gcIl-12 isoforms were modified in lymphocytes, the involvement of gcTgf-β1 in mediating these effects was examined. RgcTgf-β1 (100 ng/mL) significantly inhibited gcIl-12AB-stimulated il-17a/f1 and ifn-γ gene expression (Figures 9A, B) and gcTgf-β1 also significantly inhibited gcIl-12BB-elevated il-17a/f1 and ifn-γ gene expression (Figures 9C, D). Immunoneutralization of gcTgf-β1 secreted from the cells by using an anti-gcTgf-β1 mAb (1:2000 diluted) could enhance il-17a/f1 mRNA expression alone or in combination with gcIl-12BB (Figure 9E), but immunoneutralization of gcTgf-β1 had no effect on ifn-γ mRNA expression (Figure 9F). Moreover, ALK5 inhibitor (2 μM) was able to up-regulate il-17a/f1 but not ifn-γ mRNA expression alone, and further stimulated gcIl-12BB-induced il-17a/f1 and ifn-γ transcription (Figures 9G, H). Additionally, rgcTgf-β1 (100 ng/mL) was effective in reducing gcIl-12BB-triggered phosphorylation of Stat3 in the cells (Figure 9I).

DISCUSSION

Teleost-specific WGD generates two or three p35 paralogues in different fish species (10). In addition to one gcp35 gene reported previously (15), we found another p35 gene in grass carp (Figure S1), and these gcp35 paralogues (Figure 1) may have arisen from a common ancestral gene. These findings raised a question of whether the roles of distinct p35 paralogues are the same.
Given that p35 subunit is a rate-limiting factor for the heterodimeric IL-12 generation in both fish and mammals (4, 11, 14, 34, 35), the inducible expression patterns of p35 may determine the role of p35 paralogues (11). In rainbow trout and amberjack, bacteria are able to stimulate both p35a and p35b transcription in spleen and head kidney leukocytes (12, 13), indicating a possible involvement of p35 paralogues in the inflammatory response to pathogen challenges. However, these findings do not provide information on the discrepancy of their roles in fish. Up to now, modulation on the expression of three p35 paralogues (p35a1, p35a2 and p35b) by LPS, poly I:C, and pro-inflammatory cytokines has been observed in head-kidney cells of Atlantic salmon (11). However, these stimulatory effects on p35 paralogues expression are minor except that poly I:C, which markedly induced the expression of p35a1 and p35a2. This was potentially due to the mixed cell types in head-kidney cells as described by the authors (11). In the present study, we used grass carp monocytes/macrophages as a cell model considering that macrophages are the major physiological producers of IL-12 (36, 37). Results showed that poly I:C and rgcIfn-γ visibly augmented the expression of gcp35a and gcp35b, respectively, and we elucidated the signaling mechanisms responsive for these findings (Figure 2). It is noteworthy that the dramatic up-regulation of poly I:C on p35a but not p35b parologue is observed in both grass carp and Atlantic salmon (11), suggesting the role of p35a parologue in response to viral infection in fish. In view of IFN-γ being the major target of IL-12, the intense stimulation of rgcIfn-γ on gcp35b expression
indicated a “positive feedback loop” by local interaction between IL-12 and Ifn-γ in fish, thereby reinforcing the role of p35b in magnifying or maintaining IL-12 and Ifn-γ signaling. In addition, LPS had no effect on both gcp35 genes, but it can significantly up-regulate the mRNA levels of gcp40 paralogues in periphery blood lymphocytes (16) and their protein secretion in HKLs (30), indicating different roles of p35 and p40 subunits in fish.

In fact, our previous studies have reported that gcp40 subunits can be independently released and have their own functions (23, 30) as seen in mammals (38, 39). Our data provide a clue for understanding the diverse roles of IL-12 isoforms in fish immunity.

In mammals, it is well known that IL-12 is a disulfide-bridged heterodimer comprising a p35 and a p40 subunit (1, 40). Using grouper as the model, Tsai et al. suggest that the inter-chain disulfide bond between IL-12 subunits is conserved from teleosts to mammals IL-12 (41). In agreement with this, our results together with other reports disclosed the existence of the conserved cysteine residues in p35 and p40 subunits which can potentially form the inter-chain disulfide bond in grass carp and other fish species (Figure S2) (16, 41–43). These findings prompted us to perform 3D structural modeling analysis, and the relative reliability of the predicted models was supported by QMEANDisCo Global scores. Results showed that gcp40c could not form heterodimers due to lacking the cysteine residues responsible for the formation of inter-chain disulfide bond. Similarly, common carp p40c also lacks the key cysteine residue to form the inter-chain disulfide bond with common carp p35 subunit (43). Accordingly, it is possible that there are four gcIl-12 heterodimers (gcp35a/gcp40a, gcp35a/gcp40b, gcp35b/gcp40a and gcp35b/gcp40b). Furthermore, given that the secreted IL-12 reflects the existence of heterodimer, we detected the protein samples from the culture media of HEK293 cells transfected with gcp35a/b-FLAG and gcp40a/b/c-HIS and analyzed under non-reducing conditions, thereby providing direct evidence for the generation of gcIl-12 isoforms. As shown in Figure 4, the MWs of gcp35a (35 kDa), gcp35b (25 kDa), gcp40a (55 kDa), gcp40b (50 kDa) and gcp40c...
(43 kDa) were bigger than their predicted sizes (gcp35a, 23 kDa; gcp35b, 23 kDa; gcp40a, 40 kDa; gcp40b, 39 kDa and gcp40c, 37 kDa) with varying degrees, indicating the occurrence of glycosylation of these subunits. In fact, IL-12 is generally considered as a glycoprotein (14, 40, 44), and it has been demonstrated that the glycosylation of IL-12 family cytokines affects the biogenesis and function of these cytokines (45). The gcp40c did not form heterodimers with two gcp35 paralogues, confirming the notion that gcp40c cannot form an inter-chain disulfide bond. In addition, it is worth mentioning that a band with more than 100 kDa of MW was detected by anti-HIS antibody (Figure 4B) but not anti-FLAG antibody (Figure 4A) in the lanes loaded with the sample of gcp40a and gcp35a/b overexpression, indicating the preferential formation of gcp40a homodimer. This might result in an obstacle to generate heterodimer of gcp40a with gcp35a/b. Taken together, it was suggested that only two combinations of the subunits (gcp35a/gcp40b and gcp35b/gcp40b) could form IL-12 heterodimers. In the past years, although the recombinant fish IL-12 isoforms have been prepared based on the co-expression of p35 and p40 subunits (12, 14), the evidence for the existence of heterodimeric IL-12 isoforms is still lacking. Our results

**FIGURE 9** | The effects of gcTgf-β1 on rgcIl-12AB- and rgcIl-12BB-induced il-17a/f1 and ifn-γ mRNA expression. Lymphocytes were treated with 1000 ng/mL of rgcIl-12AB (A, B) and rgcIl-12BB (C, D) in the presence or absence of rgcTgf-β1 (100 ng/mL) for 12 h. (E, F) Lymphocytes were exposed to rgcIl-12BB (1000 ng/mL) in the presence or absence of gcTgf-β1 mAb (1:1000 diluted) for 12 h. (G, H) Lymphocytes were incubated with rgcIl-12BB (1000 ng/mL) in the presence or absence of ALK5 inhibitor (TGF-β1 RI Kinase inhibitor VIII, 2 µM) for 12 h. Then the levels of il-17a/f1 and ifn-γ mRNA were detected by qPCR. Relative mRNA levels were analyzed using β-actin as an internal reference and expressed as the fold changes of the control group (blank column). Data are shown as mean ± SEM (N = 4). Different letters indicate significant differences at p < 0.05. (I) Phosphorylation of Stat3 was detected in lymphocytes incubated with rgcIl-12BB (1000 ng/mL) in the presence or absence of rgcTgf-β1 (100 ng/mL) for 20 min.
uncovered that the generation of IL-12 isoforms is selective although there are multiple p35 and p40 paralogues in fish. This figures out the direction to prepare recombinant IL-12 proteins.

Along this line, rgcIl-12AB and rgcIl-12BB were prepared in CHO cells and their sizes were bigger than the predicted MWs (Figure S7). This is in agreement with the results of the glycosylation site prediction of gcp35a/b and gcp40b (Figure S3) and the glycylolase digestion assay (Figure S8). Consistent with the classical function of IL-12 to regulate IFN-γ expression (46, 47), rgcIl-12AB and rgcIl-12BB could increase ifn-γ gene expression and secretion in grass carp HKLs (Figure 5). This finding was further confirmed by the potential of gcIl-12AB and gcIl-12BB to stimulate ifn-γ transcription in both lymphocytes and monocytes/macrophages (Figure 6), strengthening the role of gcIl-12 isoforms in host defense via inducing Ifn-γ production as seen in mammals (48–50).

Unexpectedly, rgcIl-12AB and rgcIl-12BB were effective in modulating the il-17a/fl gene expression in lymphocytes but not monocytes/macrophages, indicating the novel function of IL-12 involving in Th17-like response in fish for the first time. In mammals, it is well known that as a hallmark cytokine of the Th17 cell, IL-17 production is mainly manipulated by IL-23 through STAT3/RORγt signaling pathways (51, 52). In teleosts, our previous study has proved that grass carp Il-23 isoforms also display the ability to trigger Th17-like response by Stat3 signaling (53). In this study, our results suggested that rgcIl-12 isoforms possessed a similar function to Il-23, and this notion was supported by the analysis of the signaling mechanisms that rgcIl-12BB up-regulated il-17a/fl transcription through Stat3/RORγt pathways in lymphocytes (Figure 8). Intriguingly, grass carp p40 isoforms also show the potential to mediate Th17-like responses by similar signaling pathways (23). Accordingly, the rgcIl-12 isoforms shared the same regulatory function with rgcIl-23 and rgcp40 isoforms on Th17-like responses. These findings raised a possibility that common Il-12/23p40 receptor (Il-12rB1) signaling may play a role in mediating Th17-like response and indicated the important role of Il-17a/fl in fish immunity. In agreement with this notion, mammalian IL-17 can effectively recruit neutrophils (54) and regulate tissue inflammation such as intestinal inflammation (55), and our previous study suggests that gcIl-17a/fl can recruit immune cells through producing chemokine Cxcl-8 (56).

Additionally, the pleiotropic properties of gcIl-12AB and gcIl-12BB prompted us to find a way to control gcIl-12 signaling. Fortunately, in accordance with the role of TGF-β1 as a classical negative regulator for IL-12 signal in IFN-γ production in mammals (57), we found that rgTGF-β1 suppressed two gcIl-12 isoforms-stimulated transcription of il-17a/fl and ifn-γ via Stat3 signaling in grass carp lymphocytes (Figure 9), suggesting an intrinsic regulatory route for restricting IL-12 signaling in fish.

Taken together, our works uncovered different expression patterns of two gcp35 paralogues and the exact composition of gcIl-12 isoforms, and explored a new function of gcIl-12 isoforms. These data provide new insights into the generation and function of heterodimeric cytokine isoforms expanded by teleost-specific WGD events during evolution.

### DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/Supplementary Material.

### ETHICS STATEMENT

The animal study was reviewed and approved by University of Electronic Science and Technology of China Experimentation Ethics Review Committee.

### AUTHOR CONTRIBUTIONS

HZ and XQ conceived and designed the experiments. XQ performed the experiments and analyzed the data. HZ and XQ wrote the manuscript. XW, AZ, and KY participated in the design of the study. HS, DW, and JR helped analyzed experiments and data. HZ edited the manuscript and provided reagents and experiment space. All authors contributed to the article and approved the submitted version.

### FUNDING
