The kidney is an important organ for controlling the volume of body fluids, electrolytic balance and excretion/reabsorption of endogenous and exogenous compounds. Among these renal functions, excretion/reabsorption of endogenous and exogenous substance is very important for the maintenance of physiological homeostasis in the body. Recently discovered organic anion transporters (OAT or SLC22A) have important roles for renal functions. It is well known as drug transporter. Several isoforms belong to SLC22A family. They showed different transport substrate spectrums and different localizations within the kidney. Their gene expressions are changed by some stimulus. The functional transport properties are regulated by protein kinase C. In addition, the function of organic anion transporters are also regulated by protein–protein interaction, such as caveolin which is compositional protein of caveolae structure. In this review, we will give an introduction of organic anion transporters and its regulatory mechanisms.

Key Words: Kidney, Organic anion, Multispecific organic anion transporter, Tubular secretion, Xenobiotics, Renal localization, Caveolin

Introduction

The kidney, as well as the liver, plays a primary role in the excretion of endogenous/exogenous compounds and their metabolites1-5. In addition to glomerular filtration, the kidney excretes charged compounds via carrier-mediated pathways, which are organic anion transport pathways, in renal proximal tubular cells6-9. Particularly the organic anion transport pathway has been shown to mediate the elimination of various drugs including anti-human immunodeficiency virus therapeutics, non-steroidal anti-inflammatory drugs, antitumor drugs, antibiotics, diuretics, and antihypertensives10. These compounds are chemically heterogeneous substances possessing a carbon backbone and a net negative or positive charge at physiological pH. A great variety of endogenous and exogenous substances that are harmful to the body can be classified into organic anions, and their elimination is therefore essential for the maintenance of homeostasis. Excretory organs such as the kidney, liver and intestine defend the body against potentially harmful effects of these compounds by biotransformation into less active metabolites and the excretory transport process. Particularly in the kidney, drugs and environmental toxicants are eventually excreted into the urine, either in the unchanged form or as biotransformation products. This renal excretion is closely related to physiological events occurring in nephrons, i.e., filtration, secretion, and reabsorption.

More than 80 years ago, it was already observed that phenolsulfonphthalein, an organic anion, was highly concentrated in the renal convoluted tubules, indicative of the tubular secretion process11. Transepithelial transport of organic anions in proximal tubules is
carried out by two distinct transporters: first, organic anions are transported from the blood by basolateral organic anion transporter(s), and subsequently effluxed into the tubular lumen by luminal transporter(s). Until early 1990s, renal organic anion transport has been considered to be carried out by several carrier proteins that show wide substrate specificity. Various anionic compounds have been indicated to be taken up into the proximal tubular cells by the "classical PAH (p-aminophenol) transporter". Recently, several organic anion transporters were reported from the kidney, liver, and olfactory mucosa. In addition, there are carrier proteins to transport organic anions such as organic anion transporting protein, multi drug resistance protein or p-glycoprotein, and so on. Therefore, in order to help reader’s comprehension, this review will focus on the present knowledge of molecular properties of renal organic anion transporters (OAT, SLC22A).

**Molecular structure of organic anion transporter**

In 1997, Sekine and Sweet et al. independently isolated the PAH transporter protein from rat kidney (OAT1/ROAT1) employing the expression cloning technique. OAT1 and ROAT1 are identical and will be collectively referred to as OAT1. OAT1 is a 551-amino-acid protein with 12 putative transmembrane domains (Fig. 1). Other members of OAT have 535–568 amino acid residues and also have 12 membrane spanning domains. The molecular structure of OAT1 has no similarity with those of other members of polyspecific organic anion transporter families, e.g., the organic anion transporting polypeptide (oatp) or the multidrug resistance-associated protein (Mrp) families. The amino acid sequence alignment of OATs shows that they have relatively high homology from 36% to 50% (Table 1).

The all members of the OAT family have several protein kinase C (PKC) sites in predicted large loops between the sixth and seventh membrane spanning domains (Fig. 1). The transport function of OAT1, OAT3 and OAT4 is regulated by PKC. The PAH transport by rOAT1 and hOAT1 expressed in *Xenopus laevis* oocytes and in HeLa cells, respectively, was inhibited after treatment of cells with phorbol esters. This phorbol-ester-induced inhibition of PAH transport was prevented by staurosporin, suggesting an inhibitory role of protein kinase C in OAT1. The uptake functions of [3H] estrone sulfate or [3H] dehydroepiandrosterone sulfate by OAT3 and OAT4 in overexpressed S2 cells or BeWo cells were also atte-

Functional characteristics of organic anion transporter

A number of endogenous and exogenous organic anions are secreted in the renal proximal tubules. The active transepithelial secretion of organic anions into the urine is mediated by two types of transporter proteins existing in the basolateral and luminal membranes of the renal proximal tubules. The first step is the uptake. Tubular secretion of organic anions occurs in two transmembrane transport processes (Fig. 2). When considering the electrical potential inside a cell of the proximal tubule, the basolateral uptake of organic anions is an uphill transport process. In 1987, Shimada and coworkers reported that uptake of para-aminohippuric acid (PAH), a typical substrate of renal organic anion transport system, was dramatically enhanced in the presence of an outward α-ketoglutarate gradient\(^{20}\). The PAH is taken up by proximal tubule cells in exchange for intracellular dicarboxylates, that are then returned to the cells via the Na\(^+\)-dicarboxylate cotransporter. These findings indicate that the PAH transporter is a tertiary active transporter. Na\(^+\), K\(^+\) ATPase (a primary active transporter) generates the sodium ion gradient between the plasma membrane\(^{21}\), and the electrochemical gradient of the sodium ions derives the transport of dicarboxylates via the Na\(^+\)-dicarboxylate cotransporter (a secondary active transporter)\(^{22}\). Using the gradient of dicarboxylates, the PAH transporter takes up organic anions in exchange for the dicarboxylates (a tertiary active transporter). In addition to this classical PAH transporter, an additional uptake system has been characterized employing bulky organic anion fluorescein-methotrexate as a substrate\(^{23}\). Uptake of fluorescein-methotrexate is independent of Na\(^+\) and is not inhibited by PAH or glutarate. The molecular identity of this transporter has not yet been established.

Molecular identification and tissue distribution of OATs

1. OAT1

The transport properties of OAT1 has been characterized functionally using Xenopus oocytes and the cell expression system (Table 2). The cloned OAT1 has been expressed in Xenopus laevis oocytes\(^{10, 14-16, 24-26}\), COS-7 cells\(^{19}\), or HeLa cells\(^{16}\). The uptake ratio of radiolabeled PAH in cells expressing these carriers was increased compared with that water-injected oocytes or mock-transfected cells, respectively.
Table 2. Molecular Characteristics of Organic Anion Transporters in the Kidney

| Transporter (HGNC name) | Species | Accession Number | Tissue distribution | Substrates |
|-------------------------|---------|------------------|---------------------|------------|
| OAT1 (SLC22A6)          | Human   | AB009697         | kidney, brain       | PAH, α-KG, cAMP, various anionic drugs |
|                         | Rat     | AB004559         | kidney, brain       |            |
|                         | Mouse   | U52842           | kidney, brain       |            |
| OAT2 (SLC22A7)          | Human   | AF097518         | kidney, liver       | α-KG, salicylate, PAH, dicarboxylate |
|                         | Rat     | L27651           |                     |            |
|                         | Mouse   |                 |                     |            |
| OAT3 (SLC22a8)          | Human   | AF097491         | kidney, liver, eye  | PAH, ochratoxin A, estrone sulfate, cimetidine |
|                         | Rat     | AB017466         | kidney, liver, eye  |            |
|                         | Mouse   | BC022387         | kidney, liver       |            |
| OAT4 (SLC22a11)         | Human   | AB026198         | kidney, placenta    | Estrone sulfate, dehydroepiandrosterone sulfate, ochratoxin A |
| OAT5 (SLC22a19)         | Rat     | AI058341         | kidney              | Estrone sulfate, dehydroepiandrosterone sulfate, ochratoxin A |

HGNC: HUGO Gene Nomenclature Committee

reported Km values range between 5 and 70 µM (5 and 9 µM for hOAT116, 20); 37 µM for mOAT119; 14 and 70 µM for rOAT110, 14) and 21 µM for flounder OAT127. Uptake of PAH by rOAT1, hOAT1, and fOAT1 was trans-stimulated by intracellularly accumulated α-ketoglutarate or glutarate. Similarly, efflux of radio-labeled glutarate from OAT1-expressing oocytes was trans-stimulated by PAH in the incubation medium28. It was proved that OAT1 acts as a PAH/ dicarboxylate antiporter. In addition to PAH, rOAT1 mediated the transport of various organic anions, including endogenous organic anions, such as prostaglandin E2 (PGE2), cyclic guanosine monophosphate (cGMP), cyclic adenosine monophosphate (cAMP), dicarboxylic acid and urate, and exogenous ones, including a number of anionic drugs such as β-lactams, nonsteroidal antiinflammatory drugs (NSAIDs), antiviral drugs, and methotrexate10, 15, 28–31. The affinities of these compounds for OAT1 were very similar to those reported for those of the basolateral PAH transporter. In addition, the hydrophobicity and the strength of the anionic charge of substrates appear to be closely related to their affinity for OAT132. OAT1 also transports ochratoxin A33 that is well known as the etiologic agent responsible for Balkan nephropathy. When OAT1-overexpressing cells and mock-transfected cells were exposed to ochratoxin A, decreased cell viability was observed in OAT1-expressing cells, which were recovered by inhibition of the OAT1-mediated uptake of ochratoxin A. This result suggests that OAT1 is associated with proximal tubular damage caused by anionic toxicants33, 34.

Recently, an electrophysiological approach was used to demonstrate translocation of organic anions by fOAT1-expressing Xenopus oocytes35. PAH, etacrynic acid, bumetanide, and tienilic acid evoked an inward current. In contrast to these compounds, probenecid and furosemide did not generate an inward current.

The tissue distribution of cloned rat, mouse, and human OAT1 is investigated by northern blot analysis (Table 2)10, 14–16, 19, 25, 26. rOAT1, mOAT1, and hOAT1 mRNAs are expressed predominantly in the kidney and very weakly in the brain. In the rat kidney, rOAT1 is localized in the middle portion of proximal tubules (S2 segment) as determined by in situ hybridization30. Immunohistochemical localization also demonstrated the rat36, 37 and human OAT125 proteins are restricted to the S2 segment of proximal tubular cells. Western blot analysis revealed that the rOAT1-encoded protein size was about 77 kDa. This rOAT1 protein was up-regulated by infusion of chronic furosemide or hydrochlorothiazide38.
2. OAT2

OAT2 has cloned by the membrane protein previously called the novel liver transporter (NLT), but whose transport substrates had not been identified. Rat OAT2 had 42% amino acid sequence homology with rOAT1, and was shown to be a member of the OAT family (Table 1). rOAT2 mediated the sodium-independent transport of salicylate (Km=88 µM) and α-ketoglutarate (Km=18 µM). rOAT2 also mediated the transport of PGE2, methotrexate, acetylsalicylate, and PAH (Table 2). rOAT2 mRNA is predominantly expressed in the liver, and weakly in the kidney. Immunohistochemical localization also demonstrated the rat OAT2 protein is detected in the apical surface of the tubule in the medullary thick ascending limb of Henle’s loop and cortical and medullary collecting ducts. Western blot analysis revealed that the rOAT2-encoded protein size was about 60 kDa. Mouse OAT2 was isolated and characterized in 2002. Different from rOAT2, mOAT2 is 540-amino-acid protein having 88% homology with rOAT2. Gene expression of mOAT2 was quite different from that of rOAT2. In contrast to rOAT2 mRNA was expressed predominantly in liver, mOAT2 mRNA was not detected in liver with Northern blot analysis. This mOAT2 mRNA was weakly detected in female liver but not kidney. In substrate specificity, mOAT2 mediated the sodium-independent transport of glutarate (Km=15.8 µM) and PGE2 (Km=5.2 µM). Interestingly, no transport of salicylate, prototype substrate of rOAT2, was detected. The gene expression of rOAT2 in isolated hepatocytes were down-regulated by the treatment with nitric oxide.

3. OAT3

Rat OAT3, another member of the multispecific organic anion transporter family, was isolated from the rat brain by the RT–PCR cloning method based on the sequence conserved among rOAT1, rOAT2, rOAT5 and mOAT6. rOAT3 shows 49, 39, 37 and 48% identity with rOAT1, rOAT2, rOAT5 and mOAT6, respectively. When expressed in Xenopus oocytes, rOAT3 mediated the uptake of organic anions such as estrone sulfate (Km=2.3 µM), ochratoxin A (Km=0.74 µM), and PAH (Km=65 µM), and cimetidine (Table 2). OAT3 also interacted with anionic neurotransmitter metabolites, such as epinephrine, norepinephrine, and serotonin. The transport mode of OAT3 was sodium-independent, and no trans-stimulatory effect of estrone sulfate, PAH, or ochratoxin A was detected in used Xenopus oocyte expression system. When rOAT3 is expressed in cells, rOAT3-mediated estrone sulfate uptake is enhanced compared with that in the case of mock-transfected cells. When cRNA injected Xenopus oocyte or renal slice were preloade with dicarboxylate, the transport of substrate mediated rOAT3 was enhanced. This fact shows that rOAT3 is also exchanger protein. In 1999, Race et al. reported hOAT3. They failed to detect any functional properties of hOAT3. Cha et al. also reported hOAT3 in 2001. This newly cloned hOAT3 transported estrone sulfate (Km=3.2 µM), PAH (Km=87.2 µM), methotrexate (Km=10.9 µM), cimetidine (Km=57.4 µM), dehydroepiandrosterone sulfate, estradiol glucuronide, glutarate, PGE2 and so on. The difference of these two clone was that the amino acid sequences of C-terminus of newly identified hOAT3 was shorter than those of old hOAT3. rOAT3 mRNA was expressed in the liver, kidney and brain, and a weak expression was detected in the eye. hOAT3 mRNA was detected mainly in the kidney and very weakly in the brain and smooth muscle. The distribution of hOAT3 protein was observed at the basolateral membrane of proximal tubule cells.

4. OAT4

Recently, we identified the fourth member of organic anion transporter expressed in the human placenta using EST (expressed sequence tag) database searched for "query OAT1". OAT4 is a 551-
amino-acid protein with 12 putative membrane-spanning domains. hOAT4 showed 38 to 44% identity with those of other members of the OAT family (Table 1). When expressed in *Xenopus* oocytes, OAT4 mediated the high-affinity transport of estrone sulfate (Km=1.01 µM) and dehydroepiandrosterone sulfate (Km=0.63 µM) in a sodium-independent manner (Table 2). OAT4 also mediated the transport of ochratoxin A and PAH. OAT4-mediated transport of estrone sulfate was inhibited by several sulfate conjugates, such as p-nitrophenyl sulfate, a-naphthyl sulfate, B-estradiol sulfate, and 4-methylumbelliferyl sulfate. In contrast, glucuronide conjugate showed little or no inhibitory effect on the OAT4-mediated transport of estrone sulfate. Recent report has shown that the transport mode of hOAT4 was also organic anion/dicarboxylate exchanger. Northern blot analysis revealed that OAT4 mRNA is abundantly expressed in the placenta as well as in the kidney. OAT4 is the first member of the multispecific organic anion transporter family that is expressed abundantly in the placenta. OAT4 might be responsible for the elimination and detoxification of harmful anionic substances from the fetus.

5. OAT5

The sixth member of OAT was recently identified from murine olfactory mucosa. Based on sequence homology proposed to be an organic anion transporter: OAT6. However, they did not show any functional evidence. In this year, Schnabolk and coworkers have reported functional properties of OAT6 using X. laevis oocytes and transfected CHO cells. Transport of estrone sulfate by mOat6 was demonstrated to be saturable having Km values of 109.8 µM in oocytes and 44.8 µM in CHO-mOat6 cells. This mOAT6-mediated estrone sulfate uptake was inhibited by 2,4-dichlorophenoxyacetate, salicylate, probenecid, and penicillin G. Accumulation of estrone sulfate mediated by mOat6 was significantly trans-stimulated by glutarate indicating that mOAT6 functions as an organic anion/dicarboxylate exchanger.

**Functional regulation by caveolin, a scaffolding protein**

In recent decades, the caveolins have been reported as being important modulating molecules that bind to some proteins that have biological functions. Caveolins are integral membrane proteins that are present in caveolae, the small flask-shaped and detergent insoluble invaginations in the plasma membrane (Fig. 3), and they have been implicated as functioning in the

---

**Fig. 3.** The structure of caveolae in plasmamembrane. The small flask shapes indicated by arrow were caveolae (from Vol. 46: H2222, Am J Physiol, 1999). Bar. 120 nm.
vesicular transport processes. Recent studies have shown that several transporter proteins including p-glycoprotein\textsuperscript{53}, cationic amino acid transporter\textsuperscript{54}, glucose transporter\textsuperscript{55}, and sodium–calcium exchanger\textsuperscript{56} are localized in caveolin–enriched lipid raft microdomains and they are regulated by caveolins. The caveolin–binding motif is a protein–protein interaction and is composed of eight to nine amino acid residues: 8XX888888 or 8XXX8XXX8 (where X is any amino acid, and 8 designates aromatic amino acids like Trp (W), Phe (F) or Tyr (Y) and X can be any amino acids). The scanning of rOAT1 and rOAT3 amino acid sequence showed several caveolin–binding motifs within the transmembrane domain or near the intracellular surface of the plasma membrane. Recently Kwak et al. have reported that rOAT1 and rOAT3 proteins were existed in caveolae enriched fraction isolated by sucrose gradient ultracentrifugation from rat kidneys\textsuperscript{57, 58}. The proteins of OATs and caveolins were co–precipitated by each respected antibodies (Fig. 4). When the rOAT1 and rOAT3 cRNA were expressed with antisense oligodeoxynucleotide of caveolins, the transport ability of rOAT1 or rOAT3 was decreased (Fig. 5). These results show that functional properties was regulated by scaffolding protein as well as protein kinase C.

**Conclusion**

The past few years have witnessed great advances in our knowledge of the molecular pharmacology of renal organic anion transport. The organic anion transport system is also important as a drug or xenobiotics transport system. The techniques for molecular biology enabled us to obtain much information about the identity of the organic anion transporters. The mechanism of excretion of organic anions into the primary urine is unknown. Understanding the detailed transport mechanism and distribution of each transporter in the kidney will give us much clues about renal drug clearance, drug–drug interaction, drug targeting to the kidney, and xenobiotic− or drug− induced nephropathy.
