Home and community-based services coordination for homebound older adults in home-based primary care

Gregory J. Norman*, Amy J. Wade, Andrea M. Morris and Jill C. Slaboda

Abstract

Background: Medically complex vulnerable older adults often face social challenges that affect compliance with their medical care plans, and thus require home and community-based services (HCBS). This study describes how non-medical social needs of homebound older adults are assessed and addressed within home-based primary care (HBPC) practices, and to identify barriers to coordinating HCBS for patients.

Methods: An online survey of members of the American Academy of Home Care Medicine (AAHCM) was conducted between March through November 2016 in the United States. A 56-item survey was developed to assess HBPC practice characteristics and how practices identify social needs and coordinate and evaluate HCBS. Data from 101 of the 150 surveys received were included in the analyses. Forty-four percent of respondents were physicians, 24% were nurse practitioners, and 32% were administrators or other HBPC team members.

Results: Nearly all practices (98%) assessed patient social needs, with 78% conducting an assessment during the intake visit, and 88% providing ongoing periodic assessments. Seventy-four percent indicated 'most' or 'all' of their patients needed HCBS in the past 12 months. The most common needs were personal care (84%) and medication adherence (40%), and caregiver support (38%). Of the 86% of practices reporting they coordinate HCBS, 91% followed-up with patients, 84% assisted with applications, and 83% made service referrals. Fifty-seven percent reported that coordination was 'difficult.' The most common barriers to coordinating HCBS included cost to patient (65%), and eligibility requirements (63%). Of the five most frequently reported barriers were associated with practices reporting it was 'difficult' or 'very difficult' to coordinate HCBS (OR from 2.49 to 3.94, p-values < .05).

Conclusions: Despite the barriers to addressing non-medical social needs, most HBPC practices provided some level of coordination of HCBS for their high-need, high-cost homebound patients. More efforts are needed to implement and scale care model partnerships between medical and non-medical service providers within HBPC practices.

Keywords: Home-based primary care, Community-based services, Care coordination, Homebound

Background

Approximately two million older adults aged 65 and older in the United States meet the criteria for being homebound [1, 2]. Homebound older adults have great difficulty living in their home independently, have high-levels of frailty and physical disability, and often have cognitive, behavioral, and psychiatric impairments [3, 4]. Without regular access to primary preventative care, they resort to high emergency department and hospital use as a way of coping with fluctuations in their physical health [5, 6]. Homebound older adults respond well to routine medical care provided in their home, known as home-based primary care (HBPC), because it is effective at keeping patients medically stable, preventing hospitalization, and reducing medical spending [5–9]. HBPC is a multidisciplinary team-based approach to providing longitudinal in-home medical care to high-need high-cost patients with limited mobility. It has been shown to be a care model that reduces costs per patient while maintaining quality of care as well as patient and provider satisfaction compared to usual care [10–12].
major advantage of long-term care provided in the home is that it enables the physician to evaluate the patient’s home environment, and be responsive to changes in health status, patient goals, and family caregiving capacity [13]. Unfortunately, of the 2 to 4 million people in the U.S. who are homebound only about one quarter receives medical care at home [2].

Many HBPC practices in the U.S. are provider-led by a physician or nurse practitioner. The practice may also include a registered nurse, and medical assistants who support providers by triaging patients, assisting with patient intakes, and handling medication refills [11, 14]. Larger practices may employ administrative coordinators who provide scheduling, billing, procurement of supplies, and other administrative tasks; social workers who focus on the patient’s home environment and link patients to community supports and services; medical coders and billers; and transition nurses who facilitate the patient transfer from the hospital to the HBPC practice [3].

In addition to being medically complex, homebound older adults often have a variety of non-medical health-related social needs (also referred to as social determinants of health) that include: housing, transportation, nutrition, social support, and assistance with activities of daily living. There is evidence to suggest that unmet social needs significantly impact health outcomes, increase healthcare utilization and costs [15–18]. As a result, comprehensive HBPC must consider the full spectrum of patient needs, both medical and non-medical, to better support this complex population and enable homebound older adults to age in place [19–21]. Non-medical home and community-based services (HCBS) can allow older adults to remain in their homes and avoid long-term care facilities, a goal that is shared with HBPC providers and their patients [22]. Assessing and addressing these non-medical social needs requires coordination between medical providers and HCBS providers. However, there is a gap in understanding how HBPC practices coordinate with HCBS providers to meet patients’ unmet social needs. Specifically, more information is needed about how nonmedical services are requested, to what extent there is ongoing coordination with HCBS providers, and what factors are assessed related to patient eligibility for services.

Care management models have been developed that include coordination of medical and non-medical patient needs [5, 15, 19, 20, 23], but these models have not been widely adopted by primary care in the U.S [21]. These models typically include staff resources to conduct assessments, identify community resources/partners, and define communication pathways that can include electronic or verbal [15]. For example, a health plan and a local Area Agency on Aging (AAA) in Arizona partnered to assess for social determinants of health with high-risk, dually-enrolled Medicaid/Medicare patients living in their home and provided connections to the appropriate community services under AAA contract, conducted ongoing assessments, and shared information between AAA and the health plan [19].

Several barriers exist to connecting high-risk older adults with the HCBS services they need, many of which apply to HBPC practices. An estimated 70% of older adults in the U.S. will need HCBS at some point [24]. While many older adults want to learn about HCBS, they often lack knowledge of the available services in their area, how to secure them, or how to pay for them [24, 25]. Similarly, medical providers may not know or understand how to refer and coordinate HCBS services [25, 26]. Demand for HCBS services may be greater than the availability of services within the community [27]. Finally, a recognized significant barrier is paying for HCBS [5, 27]. In the U.S. HCBS are covered by state government Medicaid, however not all older adults who need services will meet Medicaid’s eligibility requirements, forcing individuals to pay from their personal funds [28]. Often, older adults must spend down their savings before they are eligible for Medicaid coverage [27].

Based on models such as the Chronic Care Model [29], which postulates effective care for patients with multiple chronic conditions requires systems of coordinated medical and social services, we aimed to better understand non-medical care coordination for HCBS within HBPC practices. We surveyed HBPC practices in the U.S. to learn the extent social needs of patients are assessed and coordinated, and to determine the most salient barriers HBPC providers encounter in the coordination process, and if those barriers impact the frequency of coordination for the practices. While this is mainly a descriptive study, we hypothesized barriers to non-medical care coordination would be positively associated with difficulty and frequency of coordination among HBPC providers.

**Metadata**

**Methods**

Development of the survey instrument was informed by reviewing the relevant literature and by a previous survey of members of the American Academy of Home Care Medicine (AAHCM) [3]. Additional questions were developed collaboratively through an iterative process with project team members. The final version of the survey contained 56 questions and was divided into four sections: 1.) Identifying and Assessing Non-Medical Social Needs (14 questions); 2.) Coordinating and Evaluating Home and Community-based Services (10 questions); 3.) Oral Health Care Needs (11 questions); and 4.) Practice Characteristics (21 questions). Oral health questions were not included in this analysis. Non-medical social needs were defined to include: transportation, home-delivered meals, food preparation,
personal care (e.g., bathing, toileting, etc.), housekeeping, housing assistance, home modifications and/or repairs, caregiver supports and/or training, financial advice, legal advice, case management, and medication adherence.

A link to the online survey was posted in the AAHCM electronic newsletter and was available to all AAHCM members over an eight-month period (March to November 2016). The survey was administered using SurveyGizmo software (www.surveygizmo.com). Two reminders were sent to AAHCM members to encourage participation. Western Institutional Review Board reviewed and approved exemption status for this study.

**Analysis**

The unit of analysis was the individual HBPC practice site. For multi-site house calls practices, respondents were asked to provide information about the specific practice site where they provided services. For cases where more than one response was received from a multi-site practice, responses were cross-checked by IP address and responder role within the practice to ensure that the response was not a duplication.

Data were analyzed using SAS Studio Release: 3.6 (SAS Institute Inc., Cary, NC, USA). Descriptive statistics were assessed for HBPC practice characteristics, including practice size and location, number of practice sites and settings, funding structure, and profit status. Descriptive statistics were also used to describe how HBPC practices addressed social needs, including whether HBPC providers assessed patients for social needs, and the extent they coordinated social needs as part of their HBPC practice model.

Using univariate logistic regression models, we analyzed associations between the five most common barriers to coordinating HCBS (availability of local service providers; eligibility requirements; insurance coverage; cost to patient; time delays) and three dependent variables: ‘Does your practice coordinate HCBS?’; ‘How difficult is it to coordinate HCBS?’; and of the practices that coordinate HCBS, ‘How often does the practice coordinate HCBS?’ (often/always vs. never, rarely, sometimes). A logistic regression model was also used to regress the three dependent variables on the number of barriers (0 to 5) to coordination reported.

**Results**

**Survey respondents**

A total of 150 responses to the survey were submitted online. Of the 150, eight surveys were not eligible for inclusion (respondents were not part of a HBPC practice). An additional 41 surveys were excluded due to insufficient data for analyses. The final analytic sample consisted of 101 surveys. All respondents were part of a HBPC practice located in the United States. Forty-four percent of respondents were physicians, 24% were nurse practitioners, and 32% were administrators or other HBPC team members.

**Practice characteristics**

Nearly all practices (86%) reported that 75–100% of their patients were ages 65 and older, and 26 practices (26%) indicated their entire patient population was 65 or older. Table 1 presents characteristics of the HBPC. A majority of practices (58%) were in the Northeast or the Midwest regions of the U.S. and most practices operated in urban and suburban settings. Only 13% of practices operated in rural areas. This geographical distribution of practices is comparable to a previous survey of AAHCM members [3]. Practices tended (56%) to operate independently. Most practices (63%) reported a patient census of more than 500 and consisted of a single site (74%). Group practices (68%) predominated over solo practices (32%).

Most practices (77%) reported receiving funding for HCBS through insurance reimbursement (Medicaid, Medicare Advantage); 22% reported self-pay patients; and 19% received subsidized funding from philanthropy or through a hospital or health system. Seventy-four percent of practices indicated that their dually enrolled (Medicare and Medicaid covered) patients constituted less than 50% of their practice. The most common methods of payment for HCBS was through Medicaid (40%) and self-payment from the patient (20%). Most of practices were for-profit (61%), and most practices (78%) provided services for patients with primary Medicare Managed Care.

**Assessing and addressing social needs**

Table 2 presents practice operations around assessing patients’ non-medical social needs. Nearly all HBPC practices (98%) assessed patient needs for HCBS. Seventy-eight percent provide an assessment during the intake visit, 88% provide ongoing periodic assessments, and 88% document this in the patient care plan. Referrals for HCBS were typically initiated by the healthcare provider (64%) and caregivers (12%). Seventy-four percent of providers noted that ‘most’ or ‘all’ of their patients needed HCBS in the past 12 months. The most common service needs were personal care (84%) and medication adherence (40%).

Table 3 describes current practices for coordinating and evaluating HCBS. Eighty-six percent of practices reported they coordinate HCBS for their patients, and of those who do, 85% do so ‘often’ or ‘always.’ Of these practices, the most common coordination activities were following up with patients (91%), assisting with applications (84%), and service referrals (83%). Forty-eight percent of practices had nurse practitioners provide HCBS coordination. Nearly all practices that coordinate HCBS...
connect with multiple service providers or agencies (92%). HCBS agencies were usually characterized as local community service agencies (72%), and individual HCBS providers (70%). Word of mouth from patients (44%) was the most common way of determining the quality of an HBCS provider. Only 8% assessed quality through other agencies such as AAAs, and only 1% used the internet.

Table 4 shows across all practices, 57% reported that coordination was ‘difficult’ or ‘very difficult.’ The most common barriers to coordinating HCBS included cost to patient (65%), and eligibility requirements (63%). When asked what would make coordination of services easier, no clear answer emerged. The top two answers included a point person in the practice to coordinate services for every patient (27%), and a local service that could handle...
everything (24%). Only 19% of practices reported having an EMR interoperable with HCBS providers.

**Barriers associated with HCBS coordination**

We tested associations between the five most common barriers to coordinating HCBS (i.e., cost to patient; eligibility requirements; insurance coverage; availability of local service providers; and time delays) and whether practices coordinated HCBS; how difficult it was to coordinate services; and how often practices coordinate services (Table 5). Cost to patients was the barrier most strongly associated with practices reporting they conduct care coordination (OR = 2.96, 95% CI: 0.94–9.38, p = .06). Four of the five barriers were significantly associated with HBPC practices reporting it was ‘difficult’ or ‘very difficult’ to coordinate HCBS compared to those who reported it was ‘neutral,’ ‘easy,’ or ‘very easy’ (OR ranging from 2.49 to 3.94, all p values < .05). Number of reported barriers was also associated with an increased difficulty with HCBS coordination (OR = 2.96, 95% CI: 1.32–2.37; p = .0001). Frequently providing HCBS coordination was defined as those practices providing coordination ‘always’ or ‘often’ versus ‘sometimes,’ ‘rarely,’ or ‘never.’ Among practices indicating they currently coordinate HCBS services, patient eligibility (OR 5.96, 95% CI: 1.65, 21.55; p = 0.007) and time delays (OR 9.90 95% CI: 1.22, 80.11, p = 0.032) were associated with practices providing frequent coordination. When assessing the number of reported barriers, each additional barrier

### Table 3 Practice Operations: Coordinating and Evaluating HCBS

| Survey Question                                           | N   | N%  |
|-----------------------------------------------------------|-----|-----|
| Does your practice coordinate HCBS for your patients?     | 87  | 86% |
| Yes                                                       | 87  | 86% |
| No                                                        | 14  | 14% |
| How often does the practice coordinate HCBS?             | 73  | 85% |
| Often/Always                                              | 73  | 85% |
| Rarely/Sometimes                                          | 13  | 15% |
| What level of coordination is provided? (Select all that apply) | 79  | 91% |
| Follow up with patients and caregivers                    | 79  | 91% |
| Assistance completing applications                        | 73  | 84% |
| Make service referrals                                     | 72  | 83% |
| Determine eligibility for services                         | 61  | 70% |
| Follow up with community service providers                | 55  | 63% |
| Identify services                                         | 46  | 53% |
| Assess service needs on an ongoing basis                  | 34  | 39% |
| Who in the practice is responsible for coordinating HCBS needs for patients (or caregivers)? (Select all that apply) | 41  | 48% |
| Nurse Practitioner                                        | 41  | 48% |
| Physician                                                 | 33  | 38% |
| Social Worker                                             | 25  | 29% |
| Case Manager                                              | 21  | 24% |
| Does the practice coordinate patient HCBS with one or more community service providers/agencies? | 79  | 92% |
| Yes, with more than one                                   | 79  | 92% |
| Yes, with one community service provider/agency            | 6   | 7%  |
| No                                                        | 1   | 2%  |
| What types of organizations do you coordinate services with? (Select all that apply) | 62  | 72% |
| Local community service agencies (e.g., AAA, ADRC)         | 62  | 72% |
| Individual HCBS providers                                  | 60  | 70% |
| Hospital systems                                          | 45  | 52% |
| Senior centers                                            | 44  | 51% |
| When making a referral, how do you primarily determine the quality of HCBS providers/agencies? | 38  | 44% |
| Word of mouth from patient                                | 38  | 44% |
| Other                                                     | 18  | 21% |
| Report from service provider                               | 16  | 19% |
| AAA, ADRC                                                 | 7   | 8%  |
| Internet                                                  | 1   | 1%  |

**Table 4 Barriers and Potential Solutions to Coordinating HCBS**

| Survey Question                                           | N   | N%  |
|-----------------------------------------------------------|-----|-----|
| How difficult is it to coordinate HCBS for your patients? | 56  | 57% |
| Difficult/Very Difficult                                  | 56  | 57% |
| Neutral/Easy/Very Easy                                    | 42  | 43% |
| Top barriers to coordinating HCBS for patients/caregivers (Select all that apply) | 66  | 65% |
| Cost to patient                                           | 66  | 65% |
| Eligibility requirements                                  | 64  | 63% |
| Insurance coverage                                        | 61  | 60% |
| Availability of local service providers                   | 40  | 40% |
| Time delays                                               | 40  | 40% |
| What do you think would make the coordination of HCBS easier? (Select all that apply) | 27  | 27% |
| A point person in the practice to coordinate services for every patient | 27  | 27% |
| A local service that could handle everything               | 24  | 24% |
| Other                                                     | 16  | 16% |
| More knowledge of local available services                 | 13  | 13% |
| Defined quality measures for long-term services and supports (LTSS) | 12  | 12% |
| Unknown                                                   | 9   | 9%  |
| Is your practice EMR interoperable with other HCBS providers or agencies? | 66  | 81% |
| No                                                        | 66  | 81% |
| Yes                                                       | 15  | 19% |

**Note.** *Question asked only of respondents who replied, “Yes” to “Does your practice coordinate home and community-based services?”*
increased the odds that practices were frequently, rather than infrequently, providing coordination (OR = 1.88, 95% CI: 1.18, 2.99, p = 0.008).

### Discussion

This study revealed that in the majority of HBPC practices, most or all their patients had nonmedical social needs within the past 12 months, and nearly all practices assessed these needs both initially and periodically on an ongoing basis. HBPC providers reported being actively engaged in assessing, documenting, and coordinating HCBS for their patients. Respondents indicated cost to the patient, eligibility requirements, and insurance coverage were the top barriers to coordinating HCBS.

The high patient need for HCBS reflects the patient population characterized as frail, medically complex homebound older adults, which is consistent with other reports on HBPC [14, 30]. Most of these patients are in the last years of life and their goal is often to remain at home and out of the hospital and long-term care facilities [22]. To meet this goal requires meeting the non-medical, social service needs of homebound patients. Medical care for these patients is mostly centered on keeping their chronic conditions stable and reconciling multiple medications.

Unfortunately, more than half of the providers indicated HCBS coordination was difficult or very difficult. While barriers did not differentiate if a practice coordinated HCBS, all the top five barriers were associated with HBPC practices indicating HCBS coordination was difficult. Eligibility requirements and time delays were the two barriers associated with frequency of HCBS coordination. This suggests that these two barriers may add to HBPC providers work load around HCBS coordination. The barriers HBPC providers most frequently reported their patients encountered were financial in nature, including the cost to the patient, eligibility requirements, and insurance coverage. This is consistent with other studies stating that in the U.S. Medicare coverage for HCBS is negligible, and those who need them often fall into a gap where they lack the financial means to pay for HCBS but do not meet Medicaid’s eligibility requirements to receive coverage [5, 27, 28]. Interestingly, while over three quarters of HBPC practices reported they provide medical services for Medicare Advantage (MA) patients, only about 12% of patients received HCBS through MA.

In the U.S., MA plans and other capitated payment models, as well as alternative payment models with shared risk or shared savings incentives, create opportunities to finance integrated medical and non-medical care for homebound frail older adults [15]. These models align Medicare payment incentives with conducting high-quality care to avoid high-cost medical care such as emergency department visits and hospitalizations [31]. For example, the Comprehensive Primary Care Plus Model (CPC+), an advanced primary care medical home model, is a proactive, team-based approach to care that focuses on a patient-centered care plan provided through home-visits, e-visits, and telephone [32]. The CPC+ model has several payment components including a care management fee, a performance-based incentive payment, and a fee-for-service payment. The model is specifically designed to address the longitudinal chronic care needs of medically complex older adults.

### Table 5 Associations Between Barriers to Coordination of HCBS and Coordination Difficulty and Frequency

| Barriers               | OR, p-value | OR, p-value | OR, p-value |
|------------------------|-------------|-------------|-------------|
| Provider availability  | 1.21, p = 0.75 | 3.94, p = 0.03 | 4.29, p = 0.07 |
| Eligibility requirements | 2.67, p = 0.009 | 2.49, p = 0.04 | 5.96, p = 0.007 |
| Insurance              | 2.29, p = 0.16 | 2.52, p = 0.03 | 1.07, p = 0.92 |
| Cost to patient        | 2.96, p = 0.06 | 3.01, p = 0.01 | 1.45, p = 0.55 |
| Time delay             | 1.21, p = 0.75 | 2.33, p = 0.05 | 6.1, p = 0.03 |
| Number of barriers     | 1.28, p = 0.15 | 1.77, p = 0.0007 | 1.89, p = 0.008 |

Norman et al. BMC Geriatrics (2018) 18:241
The other two top barriers to patients receiving HCBS services identified in the survey were availability of service providers and time delays. HCBS provider availability may reflect both lack of service options, and HBPC practitioners’ lack of awareness of the HCBS services available within their community [25]. Time delays and service availability both likely reflect scarce and stretched HCBS providers that may vary in quality of service delivery. Survey responses indicated there was no consistent method for HBPC practices to learn about and determine the quality of potential HCBS options. Patient word-of-mouth reports were cited as the top option providers relied upon to assess quality. A recent literature review concluded there is a need for quality measures to address the non-medical, health-related needs of older adults [33]. Lynn [28] reaffirmed these needs, stating that most communities lack a centralized system for evaluating and determining the quality and parity of services, and reforms have failed to address these needs at a local level. Interestingly, 48 U.S. states do not conduct quality assessments of HCBS in Medicaid as part of 1915(c) waivers, which allows states to shift care from institutional to community-based settings [34]. However, these measures tend to be process-oriented and not focused on the quality of care beneficiaries receive. A quality measurement framework has been recently developed by the National Quality Forum to address gaps in performance measurement of HCBS in eleven domains (e.g., person-centered planning and coordination, community inclusion, and workforce) [35].

Practices endorsed several viable options to ease the burden of HCBS coordination. About a third of practices indicated a good option would be to designate a point person in the practice to manage this process. To address the implementation of possible HCBS coordination solutions, HBPC practices can look to existing innovative models of care that are partnerships between health care and community-based organizations that have been developed and evaluated [15, 36, 37]. Evidence supports the efficacy of nutritional assistance, case management, and community outreach programs for high-need, low income older adults [38]. For example, the Geriatric Resources for Assessment and Care of Elders (GRACE) model was designed for low-income community-dwelling older adults most of whom have multiple chronic conditions. The model includes in-home assessments and an individualized care plan developed by a nurse practitioner and social worker team in conjunction with the primary care physician. In a controlled trial over a two-year intervention period, GRACE reduced hospital costs for high-risk patients [23]. Unfortunately, only 10% of GRACE program costs are covered under traditional FFS Medicare, but the program would be feasible through Medicare managed care capitated payment [21]. While this program along with several other successful programs designed for high-risk older adults have common components such as comprehensive need assessments, patient-centered care planning, caregiver engagement, and care coordination, there has not been wide-spread adoption in practice [15, 36].

Study limitations include a low response rate to the survey and reliance on self-report measures, both of which may limit the generalizability of these findings. Of the approximately 1000 members of AAHCM, we received 101 complete responses. There may be a self-selection bias where HBPC providers who are already offering HCBS assessment and coordination in their practice were more likely to complete the survey. The proportion of HBPC practices that assess, refer, and coordinate HCBS may be lower in the overall population.

The study findings are from self-report survey responses, and there was no method to validate the responses. However, we have no reason to believe respondents had a ‘social desirability’ bias to exaggerate the extent of their care coordination efforts for patients. Other study methods, such as structured interviews, might result in information about barriers that did not surface through our survey. Future studies could use mixed-methods and include other stakeholders such as patients and family members to corroborate and expand on these findings. Study strengths include a comprehensive survey of non-medical care coordination completed by a diverse sample of HBPC practices in the US.

Conclusions
Despite the barriers to coordinating HCBS, most HBPC practices in the U.S. provided some level of coordination of non-medical services for their high-need, high-cost homebound patients. More efforts are needed to implement and scale care model partnerships between medical and non-medical service providers for this vulnerable population of older adults, but adequate payment methods and quality measurements must be in place to ensure high quality care is delivered at a reasonable cost relative to other treatment options such as long-term institutional care and frequent inpatient care. Since ‘days spent at home’ verses in health care facilities, has been recognized as the preference of most patients toward end-of-life [22], it makes sense to recognize ‘days spent at home’ as a patient-centered outcome that can be achieved through integrated care of HBPC and HCBS.

Acknowledgments
We thank Dr. Bruce Leff for sharing his survey instrument previously used to assess home-based primary care practice characteristics. Portions of this work were presented at the 2016 Annual Meeting of The American Geriatrics Society.

Funding
There was no extramural support for this research. GN, AW, AM, JS are employees of the West Health Institute. They have no potential competing interests to disclose.

Availability of data and materials
The survey and dataset analyzed in the current study are not publicly available. For specific requests please contact the corresponding author.

Authors’ contributions
GN participated in the acquisition of the data, conducted data analyses, interpreted the data and prepared the manuscript for publication. AW and JS participated in the data collection, interpretation of the data and manuscript preparation. All authors approved the final version of the manuscript for publication.

Ethics approval and consent to participate
The study was conducted in accordance with the Declaration of Helsinki. Western Institutional Review Board reviewed and approved exemption status for publication. AM and JS participated in the data collection, interpretation of the data and manuscript preparation. All authors approved the final version of the manuscript for publication.

Consent for publication
NA

Competing interests
The authors declare that they have no competing interests.
