Wildly ramified covers with large genus

Rachel J. Pries: Colorado State University *

Abstract
We study wildly ramified $G$-Galois covers $\phi : Y \to X$ branched at $B$ (defined over an algebraically closed field of characteristic $p$). We show that curves $Y$ of arbitrarily high genus occur for such covers even when $G, X, B$ and the inertia groups are fixed. The proof relies on a Galois action on covers of germs of curves and formal patching. As a corollary, we prove that for any nontrivial quasi-$p$ group $G$ and for any sufficiently large integer $\sigma$ with $p \nmid \sigma$, there exists a $G$-Galois étale cover of the affine line with conductor $\sigma$ above the point $\infty$.

2000 Mathematical Subject Classification: 14H30, 14G32

1 Introduction.
Consider a $G$-Galois cover $\phi : Y \to X$ of smooth projective irreducible curves defined over an algebraically closed field $k$ of characteristic $p$. If $\phi$ is tamely ramified, the Riemann-Hurwitz formula implies that the genus of $Y$ is determined by $|G|, g_X$, the size of the branch locus $B$ and the orders of the inertia groups. This statement is no longer true when $\phi$ is wildly ramified. Not only can wildly ramified covers usually be deformed without varying $X$ or the branch locus $B$ of $\phi$, but they can be often be distinguished from each other by studying finer ramification invariants such as the conductor. The genus of $Y$ now depends on these finer ramification invariants.

This phenomenon is already apparent when one considers $\mathbb{Z}/p$-Galois covers $\phi : Y \to \mathbb{P}^1_k$ of the projective line branched only over $\infty$. Each of these can be given by an Artin-Schreier equation $y^p - y = f(x)$ where the degree $j$ of $f(x) \in k[x]$ is relatively prime to $p$. The genus $g_Y$ of $Y$ equals $(p - 1)(j - 1)/2$ and thus can be arbitrarily large.

The main point of this paper is that the same unboundedness phenomenon occurs for covers of any affine curve with any Galois group whose order is divisible by $p$. Namely, as in the case of $\mathbb{Z}/p$-covers of the affine line, the discrete invariants of covers of a fixed affine curve with fixed group can be arbitrarily large. When $G$ is an abelian $p$-group, these results are a well-understood consequence of class field theory.

*The author was partially supported by NSF grant DMS-04-00461.
Already the case of non-abelian $p$-groups does not seem to appear in the literature.

The complexity of the problem is related to the fact that the Galois group can be a simple group in which case the cover $\phi$ will not factor through a Galois cover of smaller degree. For this reason, we use the technique of formal patching.

Here are the main results. One discrete invariant for an étale cover of the affine line is its conductor (or last jump in the filtration of ramification groups in the upper numbering). Abhyankar’s Conjecture states that a $G$-Galois cover of the affine line exists if and only if $G$ is quasi-$p$, i.e. if and only if $G$ is generated by $p$-groups.

**Corollary 3.3** If $G \neq 0$ is a quasi-$p$ group and $\sigma \in \mathbb{N}$ $(p \nmid \sigma)$ is sufficiently large, then there exists a $G$-Galois cover $\phi : Y \to \mathbb{P}^1_k$ branched at only one point with conductor $\sigma$.

More generally, suppose $X$ is a smooth projective irreducible $k$-curve and $B \subset X$ is a non-empty finite set of points. Suppose $G$ is a finite quotient of $\pi_1(X - B)$ so that $p$ divides $|G|$. (These groups were classified by Raynaud [11] and Harbater [3] in their proof of Abhyankar’s Conjecture.) We show that curves $Y$ of arbitrarily high genus occur for $G$-Galois covers $\phi : Y \to X$ branched at $B$.

**Corollary 3.4** There is an arithmetic progression $p \subset \mathbb{N}$ so that for all $g \in p$, there exists a $G$-Galois cover $\phi : Y \to X$ branched only at $B$ with genus($Y$) = $g$.

In addition, we give a lower bound for the proportion of natural numbers which occur as the genus of $Y$ for a $G$-Galois cover $\phi : Y \to X$ branched at $B$. This lower bound depends only on $G$ and $p$ and not on $X$ and $B$.

Hurwitz spaces for tamely ramified covers are well-understood by the work of [14]. The following corollary shows that the structure of Hurwitz spaces for wildly ramified covers will be vastly different.

**Corollary 3.6** For any smooth projective irreducible $k$-curve $X$ and any non-empty finite set of points $B \subset X$ and any finite quotient $G$ of $\pi_1(X - B)$ so that $p$ divides $|G|$, a Hurwitz space for $G$-Galois covers $\phi : Y \to X$ branched at $B$ will have infinitely many components.

The main results, all appearing in Section 3, use formal patching to reduce to the question of deformations of a wildly ramified cover $\hat{\phi}$ of germs of curves. We study these deformations by analyzing a Galois action on the $I$-Galois cover $\hat{\phi}$ in Section 2. Here $I$ corresponds to the inertia group of $\phi$ at a ramification point and is of the form $P \rtimes \mu_m$ where $|P| = p^e$ and $p \nmid m$. We use group theory and ramification theory to factor $\hat{\phi}$ as $\kappa \circ \phi \circ \phi^A$. The Galois group of $\phi^A$ is an elementary abelian $p$-group denoted $A$, the Galois group of $\phi$ is $P/A$, and $\kappa$ is a Kummer $\mu_m$-cover. We define a Galois action on $\phi$ which acts non-trivially only on the subcover $\phi^A$. It causes the set of wildly ramified $I$-Galois covers of germs of curves which dominate $\hat{\phi} \circ \kappa$ to form a principal homogeneous space under the action of an explicitly computable group. The effect of this Galois action on the ramification filtration of a cover is investigated in Proposition 2.7.
Another application of this Galois action can be found in [8], where it is used to study deformations of wildly ramified covers of germs of curves with control over the conductor. The results in Section 2 appear in the generality needed for this application.

I would like to thank D. Harbater, along with J. Achter and I. Bouw, for many suggestions which helped improve earlier drafts of this paper. I would also like to thank the participants of the conferences in Banff and in Leiden for enlightening conversations.

2 Galois action on wildly ramified covers.

In this section, we investigate a Galois action on a wildly ramified cover of germs of curves and its effect on the conductor. The main result is Proposition 2.7 which we use in Section 3 to control the change in the ramification filtration when we modify a Galois cover of germs of curves.

Let $k$ be an algebraically closed field of characteristic $p > 0$. Consider a compatible system of roots of unity of $k$. Denote by $\zeta$ the chosen generator of $\mu_m$. We start in Section 2.1 with background on the ramification filtrations and upper and lower jumps of a wildly ramified cover $\hat{\phi}$ of germs of curves.

2.1 Higher ramification groups.

In this section, we define the filtration of higher ramification groups of a wildly ramified Galois cover $\hat{\phi} : \hat{Y} \to U$ of germs of curves. More precisely, we fix an irreducible $k$-scheme $\Omega$ and let $U = \text{Spec}(O_{\Omega}[[u]])$. Let $\xi$ be the point of height one of $U$ defined by the equation $u = 0$.

Suppose $\hat{\phi} : \hat{Y} \to U$ is a Galois cover of normal connected germs of $\Omega$-curves which is wildly ramified at the closed point $\eta = \hat{\phi}^{-1}(\xi) \in \hat{Y}$. By [10, Lemma 2.1.4], after an étale pullback of $\Omega$, the decomposition group and inertia group over the generic point of $\eta$ are the same and so the Galois group of $\hat{\phi}$ is the same as the inertia group.

Recall that the inertia group $I$ at the generic point of $\eta$ is of the form $P \rtimes \iota \mu_m$ where $|P| = p^e$ for some $e > 0$ and $p \nmid m$. Here $\iota$ denotes the automorphism of $P$ which determines the conjugation action of $\mu_m$ on $P$.

Associated to the cover $\hat{\phi}$, there are two filtrations of $I$, namely the filtration of higher ramification groups $I_{c'}$ in the lower numbering and the filtration of higher ramification groups $I^c$ in the upper numbering. If $c' \in \mathbb{N}$, then $I_{c'}$ is the normal subgroup of all $g \in I$ such that $g$ acts trivially on $O_Y/\pi^{c'+1}$. Here $\pi$ is a uniformizer of $O_Y$ at the generic point of $\eta$. Equivalently, $I_{c'} = \{g \in I | \text{val}(g(\pi) - \pi) \geq c' + 1\}$. If $c' \in \mathbb{R}^+$ and $c'' = \lfloor c' \rfloor$, then $I_{c'}$ is defined to equal $I_{c''}$. Recall by Herbrand's formula [13, IV, Section 3], that the filtration $I^c$ in the upper numbering is given
by \( I^c = I_c \) where \( c' = \Psi(c) \) and \( \Psi(c) = \int_0^c (I^0 : I^t)dt \). Equivalently, \( c = \varphi(c') \) where \( \varphi(c') = \int_0^c dt/(I_0 : I_t) \).

If \( I_j \neq I_{j+1} \) for some \( j \in \mathbb{N}^+ \), we say that \( j \) is a lower jump of \( \hat{\phi} \) at \( \eta \). The multiplicity of \( j \) is the integer \( \ell \) so that \( I_j/I_{j+1} \simeq (\mathbb{Z}/p)^\ell \). A rational number \( c \) is an upper jump of \( \hat{\phi} \) at \( \eta \) if \( c = \varphi(j) \) for some lower jump \( j \). We denote by \( j_1, \ldots, j_e \) (resp. \( \sigma_1, \ldots, \sigma_e \)) the set of lower (resp. upper) jumps of \( \hat{\phi} \) at \( \eta \) written in increasing order with multiplicity. Note that these are the positive breaks in the filtration of ramification groups in the lower (resp. upper) numbering. By [13, IV, Proposition 11], \( p \nmid j_i \) for any lower jump \( j_i \). Herbrand’s formula implies that \( j_i - j_{i-1} = (\sigma_i - \sigma_{i-1})|I_i|/|I_j| \). In particular, \( \sigma_i|I_i/|I_{\sigma_i}| \in \mathbb{N} \) and \( \sigma_1 = j_1/m \).

We call \( \sigma = \sigma_e \) the conductor of \( \hat{\phi} \) at \( \eta \); \( \sigma \) is the largest \( c \in \mathbb{Q} \) such that inertia group \( I^c \) is non-trivial in the filtration of higher ramification groups in the upper numbering. (Note that this indexing is slightly different than in [13], where if \( x \) is a uniformizer at the branch point, then the ideal \( (x^{\sigma+1}) \) is the conductor of the extension of complete discrete valuation rings.)

If \( \phi : Y \rightarrow X \) is a \( G \)-Galois cover of projective curves branched at \( B \), we briefly recall how the genus \( g_Y \) of \( Y \) depends on the upper jumps of \( \phi \) at each branch point. Let \( I_b \) denote the inertia group of \( \phi \) at a point above \( b \in B \) and let \( mp^e \) denote its order; (for simplicity we drop the index \( b \) from the variables \( m \) and \( e \)).

**Lemma 2.1. (Riemann-Hurwitz formula)**

\[
g_Y = 1 + |G|(g_X - 1) + \sum_{b \in B} |G|\deg(R_b)/2|I_b|.
\]

\[
\deg(R_b) = |I_b| - 1 + (p - 1)m[\sigma_1 + p\sigma_2 + \ldots + p^{e-1}\sigma_e].
\]

**Proof.** The proof follows immediately from the Riemann-Hurwitz formula [6 IV.2.4], [13 IV, Proposition 4], and Herbrand’s formula [13 IV.3].

We will increase the conductor of \( \hat{\phi} \) by modifying its \( A \)-Galois subcover while fixing its \( I/A \)-Galois quotient for a suitable choice of \( A \subset I \).

**Lemma 2.2.** Suppose \( I \simeq P \rtimes \mu_m \). Suppose \( \hat{\phi} : \hat{Y} \rightarrow U \) is an \( I \)-Galois cover with conductor \( \sigma \). Then there exists \( A \subset I^\sigma \) satisfying the following hypotheses: \( A \) is central in \( P \); \( A \) is normal in \( I \); \( A \) is a nontrivial elementary abelian \( p \)-group; and \( A \) is irreducible under the \( \mu_m \)-action.

**Proof.** By [13 IV, Cor. 3 through Prop. 7], we see that \( I^\sigma \) is elementary abelian. By [13 IV, Prop. 10], if \( g \in I = I_1 \) and \( h \in I_{\Psi(\sigma)} \) then \( ghg^{-1}h^{-1} \in I_{\Psi(\sigma)+1} = \text{id} \). Thus \( I^\sigma \) is central in \( P \). The subgroup \( I^\sigma \) is normal in \( I \) by definition. Thus the conjugation action of \( \mu_m \) stabilizes \( I^\sigma \). So any choice for \( A \) among nontrivial subgroups of \( I^\sigma \) stabilized and irreducible under the action of \( \mu_m \) satisfies all the hypotheses.
Given an $I$-Galois cover $\hat{\phi} : \hat{Y} \rightarrow U$ with conductor $\sigma$, we fix $A \subset P$ satisfying the hypotheses of Lemma 22. Let $a$ be the positive integer such that $A \simeq (\mathbb{Z}/p)^a$. Let $A \rtimes_\iota \mu_m$ be the semi-direct product determined by the restriction of the conjugation action of $\mu_m$ on $P$. We fix a set of generators $\{\tau_i | 1 \leq i \leq a\}$ for $A$. Let $\overline{P} = P/A$ and $\overline{I} = I/A$.

The condition that $A$ is central in $P$ (resp. $A$ is normal in $I$) is used to define a transitive action of $A$-Galois covers on $P$-Galois covers in Section 2.2 (resp. $I$-Galois covers in Section 2.3). The conditions that $A \simeq (\mathbb{Z}/p)^a$ and that $A$ is irreducible under the action of $\mu_m$ make it easy to describe these $A$-Galois covers with equations. The condition that $A \subset I^\sigma$ is important for controlling the conductor when performing this action which is necessary in Section 2.2 for Proposition 2.4.

### 2.2 Definition of the Galois action.

Suppose $\hat{\phi} : \hat{Y} \rightarrow U$ is an $I$-Galois cover and $A$ is a subgroup in the center of $P$. This yields a factorization of $\hat{\phi}$ which we denote

$$\hat{Y} \xrightarrow{\hat{\varphi}^A} \overline{Y} \xrightarrow{\overline{\varphi}} \overline{X} \rightarrow U.$$ 

Here $\phi^A$ is $A$-Galois, $\overline{\varphi}$ is $\overline{P}$-Galois, and $\kappa$ is $\mu_m$-Galois. Let $\hat{\phi}^P : \hat{Y} \rightarrow \overline{X}$ denote the $P$-Galois subcover of $\hat{\phi}$. If $A$ is normal in $I$ and $\overline{I} = I/A$, then $\kappa \circ \overline{\varphi}$ is an $\overline{I}$-Galois cover. Let $\overline{\eta} = \phi^A(\eta)$ (resp. $\xi' = \kappa^{-1}(\xi)$) be the ramification point of $\overline{Y}$ (resp. $\overline{X}$). So

$$\eta \mapsto \overline{\eta} \mapsto \xi' \mapsto \xi.$$ 

Also, $\overline{X} \simeq \text{Spec}(\mathcal{O}_\Omega[[x]])$ for some $x$ such that $x^m = u$. The generator $\zeta$ of $\mu_m$ acts as $\zeta(x) = \zeta^h_m(x)$ for some integer $h$ relatively prime to $m$. Let $U' = U - \{\xi\}$ and $X' = \kappa^{-1}(U') = \overline{X} - \{\xi'\}$.

Consider the group $H_A = \text{Hom}(\pi_1(X'), A)$. We suppress the choice of basepoint from the notation. An element $\alpha \in H_A$ may be identified with the isomorphism class of an $A$-Galois cover of $\overline{X}$ branched only over the closed point $\xi'$. We denote this cover by $\psi_{\alpha} : V \rightarrow \overline{X}$.

**Lemma 2.3.** Let $H_A = \text{Hom}(\pi_1(X'), A)$. If $A$ is in the center of $P$, then the fibre $H_{\phi}^\sigma$ of $\text{Hom}(\pi_1(X'), P) \rightarrow \text{Hom}(\pi_1(X'), \overline{P})$ over $\overline{\phi}$ is a principal homogeneous space for $H_A$. In other words, $H_A$ acts simply transitively on the fibre $H_{\phi}^\sigma$.

**Proof.** If $\gamma \in H_{\phi}^\sigma$ and $\omega \in \pi_1(X')$, then we define the action of $\alpha \in H_A$ on $H_{\phi}^\sigma$ as follows: $\alpha \gamma(\omega) = \alpha(\omega) \gamma(\omega) \in P$. The action is well-defined since $\alpha \gamma \in \text{Hom}(\pi_1(X'), P)$ and the image of $\alpha \gamma(\omega)$ and $\gamma(\omega)$ in $\overline{P}$ are equal. The action is transitive since if $\gamma, \gamma' \in H_{\phi}^\sigma$ then $\omega \rightarrow \gamma(\omega) \gamma'(\omega)^{-1}$ is an element of $H_A$ because $A$ is in the center of $P$. The action is simple since $\alpha_1 = \alpha_2 \Leftrightarrow \alpha_1(\omega) \gamma(\omega) = \alpha_2(\omega) \gamma(\omega)$ for all $\omega \in \pi_1(X')$. \(\square\)

For more details about Lemma 2.3 in the case that $A \simeq \mathbb{Z}/p$, see [3, Section 4]. We note that the fibre $H_{\phi}^\sigma$ may be identified with isomorphism classes of (possibly}
disconnected) $P$-Galois covers $Y \to \overline{X}$ of normal germs of curves which are étale over $X'$ and dominate the $\overline{P}$-Galois cover $\overline{\phi} : \overline{Y} \to \overline{X}$.

We now give a more explicit formulation of this action. Suppose $\alpha \in H_A$ corresponds to the isomorphism class of an $A$-Galois cover $\psi_\alpha : V \to \overline{X}$ and $\gamma \in \text{Hom}(\pi_1(X'), P)$ corresponds to the isomorphism class of a $P$-Galois cover $\phi_\gamma^P : \hat{Y} \to \overline{X}$. How do $\psi_\alpha$ and $\phi_\gamma^P$ determine the cover corresponding to $\alpha \gamma$, which we denote $\hat{\phi}_\alpha^P$? Consider the normalized fibre products $Z = \hat{Y} \times_{\overline{X}} V$ and $\overline{Z} = \overline{Y} \times_{\overline{X}} V$.

\[
\begin{array}{ccc}
Z & \xrightarrow{1 \times \alpha} & \hat{Y} \\
\downarrow P & & \downarrow \phi_\gamma^P \\
V & \xrightarrow{\psi_\alpha} & \overline{X}
\end{array}
\]

Now $(\hat{\phi}_\gamma^P \times \psi_\alpha) : Z \to \overline{X}$ is the $P \times A$-Galois cover corresponding to the element $(\gamma, \alpha) \in \text{Hom}(\pi_1(X'), P \times A)$. Let $A' \subset P \times A$ be the normal subgroup generated by $(\tau_i, \tau_i^{-1})$ for $1 \leq i \leq a$. Note that $A' \simeq A$ and that $P \simeq (P \times A)/A'$. We denote by $\hat{\phi}_{\alpha \gamma}^P : W \to \overline{X}$ the $P$-Galois quotient $(\hat{\phi}_\gamma^P \times \psi_\alpha)^{A'}$ corresponding to the fixed field $W$ of $A'$ in $Z$.

\[
\begin{array}{ccc}
Z & \xrightarrow{(1 \times \alpha)^{A'}} & \hat{Y} \\
\downarrow A' & & \downarrow \phi_\gamma^A \\
W & \xrightarrow{(A \times A)/A'} & \overline{Y}
\end{array}
\]

**Lemma 2.4.** If $A$ is in the center of $P$, then the $P$-Galois cover corresponding to $\alpha \gamma \in \text{Hom}(\pi_1(X'), P)$ is isomorphic to $\hat{\phi}_{\alpha \gamma}^P : W \to \overline{X}$.

*Proof.* If $\omega \in \pi_1(X')$ then $\alpha \gamma(\omega) = \alpha(\omega) \gamma(\omega) \in P$. On the other hand, $(\gamma, \alpha)(\omega) = (\gamma(\omega), \alpha(\omega)) \in P \times A$. Since $(\gamma(\omega), \alpha(\omega)) \equiv (\gamma(\omega) \alpha(\omega), 1)$ modulo $A' = \langle (\tau_i, \tau_i^{-1}) \rangle$, the two covers give the same element of $\text{Hom}(\pi_1(X'), P)$. $\square$

### 2.3 Invariance under the $\mu_m$-action.

In this section, we consider the invariance of these covers under the $\mu_m$-Galois action. Suppose $A$ is central in $P$ and normal in $I$. Since $\iota$ restricts to an automorphism of $A$, we see that $\iota$ acts naturally on $H_A = \text{Hom}(\pi_1(X'), A)$. Denote by $H_A'$ the subgroup of $H_A$ fixed by $\iota$. In other words, the elements of $H_A'$ correspond to $A$-Galois covers $\psi : V \to \overline{X}$ branched only over the closed point $\xi'$ for which the composition $\kappa \circ \psi : V \to U$ is an $(A \rtimes_\iota \mu_m)$-Galois cover.

Suppose $\hat{\phi} : \hat{Y} \to U$ is an $I$-Galois cover where $I \simeq P \rtimes_\iota \mu_m$. Let $\gamma \in \text{Hom}(\pi_1(X'), P)$ correspond to the isomorphism class of the $P$-Galois subcover $\phi_\gamma^P$ of $\hat{\phi}$. If $\alpha \in H_A$, recall that $\hat{\phi}_\alpha^P$ is the cover corresponding to $\alpha \gamma \in \text{Hom}(\pi_1(X'), P)$.

**Lemma 2.5.** Suppose $A$ is central in $P$ and normal in $I$. Let $\alpha \in H_A$. The cover $\kappa \circ (\hat{\phi}_\alpha^P) : W \to U$ is an $I$-Galois cover if and only if $\alpha \in H_A'$.  

Proof. Let \((P \times A) \rtimes \mu_m\) be the semi-direct product for which the conjugation action of \(\alpha\) on the subgroups \((0, A)\) and \((A, 0)\) in \(P \times A\) is the same. By the hypotheses on \(A\), the subgroup \(A' = (A, A^{-1})\) is normal in \((P \times A) \rtimes \mu_m\). So by Lemma 2.21, the cover \(\kappa \circ (\phi_{\alpha, \gamma}^p) : W \to U\) is \(I\)-Galois if and only if \(Z \to U\) is \((P \times A) \rtimes \mu_m\)-Galois. One direction is now immediate: if \(\alpha \in H_A^i\), then the cover \(Z \to U\) is \((P \times A) \rtimes \mu_m\)-Galois so \(\kappa \circ (\phi_{\alpha, \gamma}^p) : W \to U\) is \(I\)-Galois.

Conversely, suppose \(\kappa \circ (\phi_{\alpha, \gamma}^p) : W \to U\) is \(I\)-Galois. Since \(\hat{Y} \to U\) and \(W \to U\) are \(I\)-Galois the action of \(\mu_m\) extends to an automorphism of \(\hat{Y}\) and of \(W\), which reduce to the same automorphism of \(\hat{Z}\). Since \(\hat{Y}\) is the fixed field of \(Z\) under \((0, A) \subset P \times A\) and \(W\) is the fixed field of \(Z\) under \(A'\), we see that the action of \(\mu_m\) extends to an automorphism of \(Z\). Thus \(Z \to U\) is \((P \times A) \rtimes \mu_m\)-Galois. Recall that \(V\) is the quotient of \(Z\) by the normal subgroup \((P, 0)\) of \((P \times A) \rtimes \mu_m\). So the quotient \(V \to U\) is \((A \rtimes \mu_m)\)-Galois which implies \(\alpha \in H_A^i\).

\[\square\]

2.4 The irreducible elementary abelian case.

In this section, we consider the case that \(A \subset P\) is a non-trivial elementary abelian \(p\)-group \((Z/p)^a\) which is irreducible under the action of \(\mu_m\) on \(P\). In other words, \(A\) satisfies all the hypotheses of Lemma 2.22 except that \(A \subset I'\). In this case, the results in Sections 2.2 and 2.3 can be made more explicit. Let \(\delta_{ij} = 1\) if \(i = j\) and \(\delta_{ij} = 0\) otherwise.

First, if \(A\) is a non-trivial elementary abelian \(p\)-group, then the cover \(\psi_{\alpha}\) corresponding to \(\alpha \in H_A\) is determined by its \(\langle \tau_i \rangle\)-Galois quotients which are given by equations \(v_i^p - v_i = r_{\alpha, i}\) with \(r_{\alpha, i} \in \mathcal{O}_\Omega[[x]][x^{-1}]\). The generator \(\tau_i \in A\) corresponds to an automorphism \(\tau_{\psi,i}\) of \(V\) given by \(\tau_{\psi,i}(v_j) = v_j + \delta_{ij}\). Given another such cover \(\psi'\) with equations \(v_i^p - v_i = r_{\alpha, i}'\), the group operation for \(H_A\) corresponds to adding the Laurent series in the Artin-Schreier equations. This yields the cover given by the equations \(v_i^p - v_i = r_{\alpha, i} + r_{\alpha, i}'\).

Next, if \(A\) is a non-trivial elementary abelian \(p\)-group, then Lemma 2.21 allows us to view the action of \(H_A\) on \(H_{\phi}\) on the ring level. The cover \(\phi_{\gamma}^p\) corresponding to \(\gamma \in \text{Hom}(\tau_i(X^\gamma), P)\) is determined from its \(\bar{\phi}\)-quotient by an \(A\)-Galois cover \(\phi_{\gamma}^A : \hat{Y} \to \hat{Y}\). This cover \(\phi_{\gamma}^A\) is determined by its \(\langle \tau_i \rangle\)-Galois quotients which are given by Artin-Schreier equations \(y_i^p - y_i = r_{\gamma, i}\). Here \(r_{\gamma, i} \in \hat{K}\) where \(\hat{K}\) is the fraction field of the complete local ring of \(\hat{Y}\) at the closed point \(\overline{\eta}\). The Galois action is given by \(\tau_{\phi, i}(y_j) = y_j + \delta_{ij}\). Note that \(w_i = y_i + v_i\) is invariant under \(\langle (\tau_i, \tau_i^{-1}) \rangle\). Thus the cover \(\phi_{\alpha, \gamma}^p : W \to \hat{K}\) is determined from \(\phi\) by the \(A\)-Galois cover \(W \to \hat{Y}\) which is determined by the equations \(w_i^p - w_i = r_{\gamma, i} + r_{\alpha, i}\). This gives an even more explicit description of the Galois action.

Furthermore, suppose \(A \subset P\) is a non-trivial elementary abelian \(p\)-group so that \(\mu_m\) acts irreducibly on \(A\). If \(\psi_{\alpha}\) is the \(A\)-Galois cover corresponding to \(\alpha \in H_A^i\), then \(\psi_{\alpha}\) is determined by any one of its \(\langle \tau_i \rangle\)-Galois quotients along with the cover \(\kappa\). Also the filtration of higher ramification groups for \(\alpha \in H_A^i\) can have only one
jump which occurs with full multiplicity \(a\). In addition, the conductor of \(\psi_\alpha\) is an integer which must satisfy a certain congruence condition.

**Lemma 2.6.** i) Suppose \(\hat{\phi} : \hat{Y} \to U\) is an \(I \simeq P \rtimes \mu_m\)-Galois cover with conductor \(\sigma\) and last lower jump \(j_c\). Suppose \(A \subset I^\sigma\) satisfies the hypotheses of Lemma 2.2. Suppose \(\alpha \in H_A^I\) has conductor \(s\). Then \(s \equiv j_c/|\mathcal{P}| \pmod{m}\).

ii) Associated to the \(\mu_m\)-Galois cover \(\kappa : \overline{X} \to U\) and the group \(A \rtimes \mu_m\), there is a unique integer \(s_e\) (such that \(1 \leq s_e \leq m\)) having the following property: if \(\alpha \in H_A^I\) has conductor \(s\) then \(s \equiv s_e \pmod{m}\).

**Proof.** i) Suppose \(|\mathcal{P}| = p^d\). Let \(y\) be a primitive element for the \(A\)-Galois extension of the function field \(\overline{K}\) of \(Y\). The valuation of \(y\) in the function field \(K\) of \(\hat{Y}\) is \(-j_e\), where \(j_e\) is the last lower jump of \(\hat{\phi}\). The equation for the \(A\)-Galois cover \(\phi^A : \hat{Y} \to \overline{Y}\) is of the form \(f(y) = r_\phi\) where \(f(y) \in O_\Omega[y]\) is a relative Eisenstein polynomial of degree \(p^a\) and \(r_\phi \in K\). From the equation, the valuation of \(r_\phi\) in \(K\) is \(p^a\) val\((y) = -p^a j_e\). It follows that the valuation of \(r_\phi\) in \(\overline{K}\) is \(-j_e\).

Also \(x\) has valuation \(p^d\) in \(\overline{K}\). This implies that there is a unit \(u_1\) of \(O_{\overline{K}}\) so that \(r_\phi = x^{-j_e/p^d} u_1\). Likewise, the equation for the \(A\)-Galois cover \(\psi : V \to \overline{X}\) is of the form \(f(v) = r_\alpha\) where \(r_\alpha = x^{-s} u_2\) for some unit \(u_2\) of \(O_\Omega[[x]]\). The generator \(\zeta\) of \(\mu_m\) acts by \(\zeta(x) = \zeta^h_m x\). So \(\zeta(v) = \zeta^{-h s} v\) and \(\zeta(y) = \zeta^{h j_e/p^d} y\).

Since \(y + v\) is in the function field of \(W\), the action of \(\zeta\) on \(y\) and \(v\) must be compatible. Thus \(s \equiv j_e/|\mathcal{P}| \pmod{m}\).

ii) It is sufficient to show that the conductors \(s_i\) of any two covers \(\alpha, \alpha_1 \in H_A^I\) are congruent modulo \(m\). This follows directly from part (i) (taking \(\hat{\phi} = \kappa \circ \alpha_1\), \(P = A\), and \(j_e = s_1\)).

2.5 Effect of the Galois action on the conductor.

At this point, we determine the effect of the Galois action on the conductor of the cover. Consider an \(I\)-Galois cover \(\hat{\phi} : \hat{Y} \to U\) with conductor \(\sigma\) and, more generally, upper jumps \(\sigma_1, \ldots, \sigma_e\) in the ramification groups \(I^c_\phi\) in the upper numbering; (here \(\sigma = \sigma_e\)). Consider \(A \subset I^\sigma\) satisfying the hypotheses of Lemma 2.2 and choose \(\alpha \in H_A^I\). By definition, \(\alpha\) corresponds to an \(A\)-Galois cover \(\psi_\alpha : V \to \overline{X}\). Let \(s \in \mathbb{N}^+\) be the conductor of \(\psi_\alpha\) and note \(p \not\mid s\). Since \(A\) is irreducible under the \(\mu_m\)-action, \(\psi_\alpha\) has ramification filtration \(I^c_\alpha = A\) for \(0 \leq c \leq s\) and \(I^c_\alpha = 0\) for \(c > s\). The action of \(\alpha\) takes \(\hat{\phi}\) to another \(I\)-Galois cover which we denote by \(\hat{\phi}^\alpha : W \to U\). Recall that \(\hat{\phi}^\alpha\) is the \(I\)-Galois cover \(\kappa \circ (\hat{\phi}^\alpha_\gamma)\) where \(\gamma \in \text{Hom}(\pi_1(X'), P)\) corresponds to the \(P\)-Galois subcover \(\hat{\phi}^P\).

The following result will be crucial in order to modify a Galois cover of germs of curves with control over the change in the ramification filtration.
Proposition 2.7. If the cover $\hat{\phi}^\alpha$ is connected, then it has conductor $\max\{s/m, \sigma\}$. More generally, the ramification filtration of $\hat{\phi}^\alpha$ is $I^c_{\hat{\phi}^\alpha} = I^c_{\hat{\phi}}$ for $0 \leq c \leq \sigma$, $I^c_{\hat{\phi}^\alpha} = A$ for $\sigma < c \leq \max\{s/m, \sigma\}$, and $I^c_{\hat{\phi}^\alpha} = 0$ for $\max\{s/m, \sigma\} < c$.

Proof. The $P$-Galois subcover $\hat{\phi}^\alpha_{\alpha\gamma} = (\hat{\phi}^\alpha)^P : W \to \mathcal{X}$ dominates $\overline{\phi} : \mathcal{Y} \to \mathcal{X}$. So after intersecting with $\overline{P}$, the ramification filtrations for $\hat{\phi}^P$ and $\hat{\phi}^\alpha_{\alpha\gamma}$ are equal, i.e. $I^c_{\hat{\phi}^\alpha} \cap \overline{P} = I^c_{\hat{\phi}^\alpha} \cap \overline{P}$.

So the only issue is to find the index at which each generator $\tau_i$ of $A$ drops out of the filtration of higher ramification groups. In fact, the jumps for the $\tau_i$ are all equal. This is because the jumps of the $\tau_i$ are the same (occurring with multiplicity $a$) for both of the covers $\hat{\phi}^P$ and $\psi_\alpha$. To complete the proof it is thus sufficient to find the conductor of the cover $\hat{\phi}^\alpha$. In particular, by Herbrand’s formula, it is sufficient to show the conductor of the $P$-Galois subcover $(\hat{\phi}^\alpha)^P$ equals $\max\{s, ms/\sigma\}$.

To do this, we investigate the filtration of the $A \times A$-Galois cover $Z \to \mathcal{Y}$. Here $s$ and $ms/\sigma$ are the relevant upper jumps of $Z \to \mathcal{X}$. Denote by $\Psi_{(\gamma, \alpha)}$ the function which takes the indexing on the ramification filtration of the $P \times A$-Galois cover from the upper to lower numbering. So the numbers $\Psi_{(\gamma, \alpha)}(s)$ and $\Psi_{(\gamma, \alpha)}(ms/\sigma)$ are the corresponding lower jumps for $Z \to \mathcal{X}$, and thus also for $Z \to \mathcal{Y}$ by [13, Proposition 2]. Also the lower (and upper) jump for $Z \to \mathcal{Z}$ is $\Psi_{(\gamma, \alpha)}(ms/\sigma)$ and for $Z \to \hat{\gamma}$ is $\Psi_{(\gamma, \alpha)}(s)$. Since the Galois group of $Z \to W$ is generated by the automorphisms $(\tau_{\gamma, i}, \tau_{\alpha, j})$ the cover $Z \to W$ has lower jump $\min\{\Psi_{(\gamma, \alpha)}(s), \Psi_{(\gamma, \alpha)}(ms/\sigma)\}$.

If $s \leq ms/\sigma$, the conductors of $Z \to W$ and of $Z \to \hat{\gamma}$ are the same; this implies that the conductor of $W \to \mathcal{Y}$ equals the conductor of $\hat{\gamma} \to \mathcal{Y}$, namely $\Psi_{\gamma}(ms/\sigma)$. Thus the conductor of $\hat{\phi}^\alpha$ is $ms/\sigma$ and the ramification filtrations for $\hat{\phi}^\alpha$ and $\hat{\phi}$ are the same. Similarly, if $s > ms/\sigma$, the conductors of $Z \to W$ and $Z \to \mathcal{Z}$ are the same; this implies that the conductor of $W \to \mathcal{Y}$ equals the conductor of $\mathcal{Z} \to \mathcal{Y}$. So the ramification filtrations for $\hat{\phi}^\alpha$ and $\mathcal{Z} \to U$ are the same, which implies that the conductor of the former is also $s/m$.

See Example [4.4] for a computational proof of Proposition 2.7 in the case that $m = 1$ and $P = \mathbb{Z}/p^2$.

2.6 Connected and smooth covers

Suppose $\hat{\phi} : \hat{Y} \to U$ is an $I$-Galois cover of normal connected germs of curves (wildly ramified with conductor $\sigma$ as above). Suppose $A \subset I^c_{\hat{\phi}}$ satisfies the hypotheses of Lemma 2.2 and $\alpha \in H_A^I$. In future applications [8] and briefly in Section 8, we need to consider questions of connectedness and smoothness for the $I$-Galois cover $\hat{\phi}^\alpha$. First, we show that the $I$-Galois cover $\hat{\phi}^\alpha : W \to U$ is almost always connected.

Lemma 2.8. If $\hat{\phi}$ is a cover of connected germs of curves, then there are only finitely many choices of $\alpha$ for which $\hat{\phi}^\alpha$ is not connected. In particular, $\hat{\phi}^\alpha$ is connected if $\hat{\phi}^P$ does not dominate $\psi_\alpha$. 

Proof. The first statement follows directly from the second since \( \hat{\phi}^P \) only dominates a finite number of \( A \)-Galois covers.

For the second statement, suppose \( \hat{\phi}^P \) does not dominate \( \psi_\alpha \). The fact that both \( Y \) and \( V \) are invariant under the \( \mu_m \)-Galois action and the fact that \( A \) is irreducible under this action imply that \( \hat{\phi}^P \) and \( \psi_\alpha \) are linearly disjoint. It follows that the curve \( Z = \hat{Y} \times_{\hat{X}} V \) is connected. If \( Z \) is connected then its quotient \( W = Z^{\phi^P} \) is connected and so \( \hat{\phi}^\alpha : W \to \overline{X} \) is a cover of connected germs of curves.

\[ \square \]

**Lemma 2.9.** If \( \hat{\phi} \) is a cover of connected germs of curves and \( \alpha \) is such that the cover \( \hat{\phi}^\alpha \) is not connected, then \( s = m\sigma \).

**Proof.** Consider the covers \( \hat{\phi} : Y \to U \) and \( \hat{\phi}^\alpha : W \to U \). Recall that \( Y \) and \( W \) are two of the quotients of \( Z \) by subgroups of \( A \times A \). The fact that \( Y \) is connected implies that \( Z \) has at most \( |A| \) components. Also \( Z \) is not connected since \( W \) is not connected. The stabilizer of a component of \( Z \) has size \( |A| \) since \( A \) is irreducible under the \( \mu_m \)-action. As a result, only one of the \( A \)-quotients of \( Z \) can be disconnected. In particular, \( \overline{Z} \) is connected.

The \( A \)-Galois covers \( Y \to \overline{Y} \) and \( \overline{Z} \to \overline{Y} \) are not linearly disjoint since their fibre product \( Z \to \overline{Y} \) is disconnected. By the fact that \( A \) is irreducible under the \( \mu_m \)-action, it follows that these two \( A \)-Galois covers are identical. Thus the \( I \)-Galois covers \( \hat{\phi} : Y \to U \) and \( \overline{Z} \to U \) are the same and thus have the same conductor. The conductor of the former is \( \sigma \). The conductor of the latter is the same as the upper jump of \( V \to U \) which is \( s/m \).

\[ \square \]

**Remark 2.10.** Note that \( \hat{\phi}^\alpha \) could be connected even if \( s = m\sigma \). The cover \( \hat{\phi}^\alpha \) is connected (and thus has conductor \( \max\{s/m, \sigma\} \) by Proposition 2.11) as long as the leading term of \( r_{\hat{\phi}} \) does not cancel the leading term of \( r_{\alpha} + r^p - r \) for any \( r \in K \). For this will guarantee that \( -\text{val}(r_{\hat{\phi}} + r_{\alpha}) = \max\{-\text{val}(r_{\hat{\phi}}), -\text{val}(r_{\alpha})\} \).

A final issue that will come up is one related to smoothness. Fix \( \Omega = \text{Spec}(R) \) where \( R \) is an equal characteristic complete local ring with residue field \( k \) and fraction field \( K \). Consider the special fibre \( \hat{\phi}^\alpha_k : W_k \to U_k \) of the cover \( \hat{\phi}^\alpha : W \to U \) of \( \Omega \)-curves. It is possible that the curve \( W_k \) is singular at its closed point \( w \). The following lemma implies that this can only occur when the ramification filtrations of \( \hat{\phi}^\alpha \) are not the same on the generic and spec.

**Lemma 2.11.** Suppose that \( \hat{\phi}^\alpha : W \to U \) is a Galois cover of normal irreducible germs of \( \Omega \)-curves with \( W_k \) reduced, \( \hat{\phi}^\alpha_k \) separable, and \( \hat{\phi}^\alpha \) étale outside \( \xi \). Let \( d_k \) (resp. \( d_K \)) be the degree of the ramification divisor over \( \xi_k \) (resp. \( \xi_K \)). Then \( d_K = d_k \) if and only if \( w \) is a smooth point of \( W_k \).

**Proof.** The value of \( d_k \) and the question of whether \( w \) is a smooth point of \( W_k \) do not depend on \( R \). The value of \( d_K \) depends only on the ramification at the generic point of \( \xi_K \). For this reason, it is sufficient to restrict to the case that \( R = k[[t]] \).

The proof then follows from Kato’s formula \[\square\] which states (under the conditions
Let \( U \) be a cover of \( U \) to do this without introducing a singularity. In other words, the special fibre increases on the generic fibre. By Lemma 2.11, it is not possible by the group elements of the condition that and let \( \tilde{\phi} \) will "deform" \( \phi \) of \( \hat{\phi} \) the special fibre of \( \hat{\phi} \) group at a ramification point \( \eta \) branched only at \( \alpha \) if \( d \) by the group elements of \( \mu \) of \( \tilde{\phi} \) is an \( \tilde{\phi} \)-Galois cover of smooth projective irreducible \( \tilde{\phi} \)-curves. Suppose \( \phi : Y \to X \) is a \( G \)-Galois cover of smooth projective irreducible \( k \)-curves branched only at \( B \). Suppose \( \phi \) wildly ramified over \( b \in X \) and let \( I \) be the inertia group at a ramification point \( \eta \) above \( b \). Let \( R \) be an equal characteristic complete discrete valuation ring with residue field \( k \) and let \( K = \text{Frac}(R) \). In this section, we will "deform" \( \phi \) to a cover \( \phi_R : Y_R \to X \times_k R \) so that the conductor of \( \phi_R \) at this wild branch point increases on the generic fibre. By Lemma 2.11 it is not possible to do this without introducing a singularity. In other words, the special fibre \( \phi_k \) of \( \phi_R \) will be singular and \( \phi \) will be isomorphic to the normalization of \( \phi_k \) away from \( b \).

More precisely, let \( \hat{\phi} : \hat{Y} \to U_k \) be the germ of \( \phi \) at \( \eta \). Here \( U_k \simeq \text{Spec}(k[[u]]) \). Let \( U_R = \text{Spec}(k[[t]][u]) \). Let \( \xi \) (resp. \( \xi_R \)) be the closed point of \( U_k \) (resp. \( U_R \)) given by the equation \( u = 0 \). For lack of better terminology, a singular deformation of \( \phi \) is an \( I \)-Galois cover \( \hat{\phi}_R : \hat{Y} \to U_R \) of normal irreducible germs of \( R \)-curves, whose branch locus consists of only the \( R \)-point \( \xi_R \), such that the normalization of the special fibre of \( \hat{\phi}_R \) is isomorphic to \( \hat{\phi} \) away from \( \xi \). (Note that the special fibre \( \phi_k \) of \( \phi_R \) is the restriction of \( \hat{\phi}_R \) over \( U_k \) (when \( t = 0 \)). The generic fibre \( \phi_K \) of \( \phi_R \) is the cover of \( U_R \times_R K = \text{Spec}(k[[t]][u][t^{-1}]) \).

3 Increasing the Conductor of a Cover.

In this section, we consider the question of increasing the conductor of a cover of curves at a wild branch point. Suppose \( X \) is a smooth projective irreducible \( k \)-curve and \( B \) is a non-empty finite set of points of \( X \). Suppose \( G \) is a finite quotient of \( \pi_1(X - B) \). When \( |B| \) is nonempty, these groups have been classified by Raynaud and Harbater (11) in their proof of Abhyankar’s Conjecture. Namely, \( G \) is a finite quotient of \( \pi_1(X - B) \) if and only if the number of generators of \( G/p(G) \) is at most \( 2g_X + |B| - 1 \). Here \( p(G) \) denotes the characteristic subgroup of \( G \) generated by the group elements of \( p \)-power order.

Suppose \( \phi : Y \to X \) is a \( G \)-Galois cover of smooth projective irreducible \( k \)-curves branched only at \( B \). Suppose \( \phi \) wildly ramified over \( b \in X \) and let \( I \) be the inertia group at a ramification point \( \eta \) above \( b \). Let \( R \) be an equal characteristic complete discrete valuation ring with residue field \( k \) and let \( K = \text{Frac}(R) \). In this section, we will “deform” \( \phi \) to a cover \( \phi_R : Y_R \to X \times_k R \) so that the conductor of \( \phi_R \) at this wild branch point increases on the generic fibre. By Lemma 2.11 it is not possible to do this without introducing a singularity. In other words, the special fibre \( \phi_k \) of \( \phi_R \) will be singular and \( \phi \) will be isomorphic to the normalization of \( \phi_k \) away from \( b \).

More precisely, let \( \hat{\phi} : \hat{Y} \to U_k \) be the germ of \( \phi \) at \( \eta \). Here \( U_k \simeq \text{Spec}(k[[u]]) \). Let \( U_R = \text{Spec}(k[[t]][u]) \). Let \( \xi \) (resp. \( \xi_R \)) be the closed point of \( U_k \) (resp. \( U_R \)) given by the equation \( u = 0 \). For lack of better terminology, a singular deformation of \( \phi \) is an \( I \)-Galois cover \( \hat{\phi}_R : \hat{Y} \to U_R \) of normal irreducible germs of \( R \)-curves, whose branch locus consists of only the \( R \)-point \( \xi_R \), such that the normalization of the special fibre of \( \hat{\phi}_R \) is isomorphic to \( \hat{\phi} \) away from \( \xi \). (Note that the special fibre \( \phi_k \) of \( \phi_R \) is the restriction of \( \hat{\phi}_R \) over \( U_k \) (when \( t = 0 \)). The generic fibre \( \phi_K \) of \( \phi_R \) is the cover of \( U_R \times_R K = \text{Spec}(k[[t]][u][t^{-1}]) \).
Lemma 2.11 shows that a deformation is singular if and only if the ramification data on the generic and special fibres are not the same.

The following proposition shows that there is always a singular deformation of \( \hat{\phi} \) with larger conductor on the generic fibre.

**Proposition 3.1.** Suppose \( \hat{\phi} : \hat{Y} \to U_k \) is an \( I \)-Galois cover of normal connected germs of curves with conductor \( \sigma \). Suppose \( A \subset I^\sigma \) satisfies the hypotheses of Lemma 2.6. Suppose \( s \in \mathbb{N} \) is such that \( p \nmid s \), \( s > m\sigma \), and \( s \equiv s_t \mod m \) (with \( s_t \) as in Lemma 2.6). Then there exists a singular deformation \( \hat{\phi}_R : Y \to U_R \) whose generic fibre \( \hat{\phi}_K : Y_K \to U_K \) has inertia \( I \) and conductor \( s/m \). In addition, \( I^c_{\phi_K} = I^c_{\phi} \) for \( 0 \leq c \leq \sigma \), \( I^{c}_{\phi_K} = 0 \) for \( c > s/m \).

**Proof.** The \( A \)-Galois subcover \( \hat{Y} \to \hat{\mathbb{Y}} \) is determined by \( \kappa \) and by the equation \( y^p - y = r_\phi \) of its \( \langle \tau_1 \rangle \)-Galois quotient (where \( r_\phi \in \bar{K} \)). Consider the singular deformation of \( \phi \) whose \( \bar{\phi} \)-Galois quotient is constant and whose \( \langle \tau_1 \rangle \)-Galois subquotient is given generically by the following equation: \( y^p - y = r_\phi + tx^{-s} \). The curve \( Y \) is singular only above the point \( (u, t) = (0, 0) \). The normalization of the special fibre agrees with \( \phi \) away from \( u = 0 \). The cover \( \hat{\phi}_R \) is branched only at \( \xi_R \) since \( u = 0 \) is the only pole of the function \( r_\phi + tx^{-s} \). When \( t \neq 0 \), by Proposition 2.7, the conductor of \( \phi_K \) is \( s \) and the statement on ramification filtrations is true.

Proposition 3.1 shows that we can increase the conductor from \( \sigma \) to \( s/m \). By Herbrand’s formula, it follows that the last lower jump increases from \( j_e \) to \( j_e + p^{e-a}m(s/m - \sigma) \). One can check that the latter number is always an integer which is not divisible by \( p \).

The next theorem uses Proposition 3.1 and formal patching to (singularly) deform a cover \( \phi : Y \to X \) of projective curves to a family of covers \( \phi_R \) of \( X \) so that the conductor increases at the chosen branch point. This family can be defined over a variety \( \Theta \) of finite type over \( k \). We then specialize to a fibre of the family over another \( k \)-point of \( \Theta \) to get a cover \( \phi' \) with larger conductor.

**Theorem 3.2.** Let \( \phi : Y \to X \) be a \( G \)-Galois cover of smooth projective irreducible curves with branch locus \( B \). Suppose \( \phi \) is wildly ramified with inertia group \( I \simeq P \times_{\kappa} \mu_m \) and conductor \( \sigma \) above some point \( b \in B \). Suppose \( A \subset I^\sigma \) satisfies the hypotheses of Lemma 2.6. Let \( s_t \) be as defined in Lemma 2.6(ii). Suppose \( s \in \mathbb{N} \) such that \( p \nmid s \), \( s > m\sigma \), and \( s \equiv s_t \mod m \). Then there exist \( G \)-Galois covers \( \phi_R : Y_R \to X \times_k R \) and \( \phi' : Y' \to X \) such that:

1. The curves \( Y_R \) and \( Y' \) are irreducible and \( Y_K \) and \( Y' \) are smooth and connected.
2. After normalization, the special fibre \( \phi_K \) of \( \phi_R \) is isomorphic to \( \phi \) away from \( b \).
3. The branch locus of the cover \( \phi_R \) (resp. \( \phi' \)) consists exactly of the \( R \)-points \( \xi_R = \xi \times_k R \) (resp. the \( k \)-points \( \xi \)) for \( \xi \in B \).
4. For \( \xi \in B, \xi \neq b \), the ramification behavior for \( \phi_R \) at \( \xi_R \) (resp. \( \phi' \) at \( \xi \)) is identical to that of \( \phi \) at \( \xi \).

5. At the \( K \)-point \( b_K \) (resp. at \( b \)), the cover \( \phi_K \) (respectively \( \phi' \)) has inertia \( I \) and conductor \( s/m \) and in addition \( \Gamma_{\phi_K} = I_c^e \) for \( 0 \leq c \leq \sigma \), \( \Gamma_{\phi_K} = \Theta \) for \( \sigma < c \leq s/m \), and \( \Gamma_{\phi_K} = 0 \) for \( c > s/m \).

6. The genus of \( Y' \) and of \( Y_K \) is \( g'_Y = g_Y + |G|(s/m - \sigma)(1 - 1/p^a)/2 \) where \( a \) is such that \(|A| = p^a\).

Proof. Let \( \eta \in \phi^{-1}(b) \) and consider the \( I \)-Galois cover \( \phi : \hat{Y}_\eta \rightarrow \hat{X}_b \). Applying Proposition 3.1 to \( \phi \), there exists a singular deformation \( \phi_R : \hat{Y}_R \rightarrow \hat{X}_R \) of \( \phi \) with the desired properties. In particular, \( \phi_K \) has inertia \( I \) and conductor \( s \) over \( b_K \). Consider the disconnected \( G \)-Galois cover \( \text{Ind}_I^G(\hat{\phi}_R) \).

The covers \( \phi_k \) and \( \text{Ind}_I^G(\hat{\phi}_R) \) and the isomorphism between their overlap constitute a relative \( G \)-Galois thickening problem. The (unique) solution to this thickening problem \([5, \text{Theorem 4}] \) yields the \( G \)-Galois cover \( \phi_R : Y_R \rightarrow X \times_k R \). Recall that the cover \( \phi_R \) is isomorphic to \( \text{Ind}_I^G(\hat{\phi}_R) \) over \( \hat{X}_{R,b} \). Also, \( \phi_R \) is isomorphic to the trivial deformation \( \phi_{tr} : Y_{tr} \rightarrow X_{tr} \) of \( \phi \) away from \( b \). Thus \( Y_R \) is irreducible since \( Y \) is irreducible and \( Y_K \) is smooth since \( Y_{tr,K} \) and \( \hat{Y}_K \) are smooth.

The data for the cover \( \phi_R \) is contained in a subring \( \Theta \subset R \) of finite type over \( k \), with \( \Theta \neq k \) since the family is non-constant. Since \( k \) is algebraically closed, there exist infinitely many \( k \)-points of \( \text{Spec}(\Theta) \). The cover \( \phi_R \) descends to a cover of \( \Theta \)-curves. The closure \( L \) of the locus of \( k \)-points \( \theta \) of \( \text{Spec}(\Theta) \) over which the fibre \( \phi_\theta \) is not a \( G \)-Galois cover of smooth connected curves is closed, \([2, \text{Proposition 9.29}] \). Furthermore, \( L \neq \text{Spec}(\Theta) \) since \( Y_K \) is smooth and irreducible. Let \( \phi' : Y' \rightarrow X \) be the fibre over a \( k \)-point not in \( L \). Note that \( Y' \) is smooth and irreducible by definition.

Properties 2-5 follow immediately from the compatibility of \( \phi_R \) with \( \text{Ind}_I^G(\hat{\phi}_R) \) over \( \hat{X}_{R,b} \) and with the trivial deformation \( \phi_{tr} : Y_{tr} \rightarrow X_{tr} \) away from \( b \).

The genus of \( Y' \) and of \( Y_K \) increases because of the extra contribution to the Riemann-Hurwitz formula. In particular, there are \(|G|/m|P|\) ramification points above \( b_K \). If \(|P| = p^a\) then by Herbrand’s formula, each ramification point has \((s/m - \sigma)mp^{e-a}\) extra non-trivial ramification groups of order \( p^a \) in the lower numbering. Thus the degree of the ramification divisor over \( b_K \) increases by \(|G|(s/m - \sigma)(1 - 1/p^a)/2\).

One can say more when \( X \simeq \mathbb{P}^1_k \) and \( B = \{ \infty \} \). By Abhyankar’s Conjecture, the non-trivial quasi-\( p \) groups are exactly the ones so that \( G \) is a finite quotient of \( \pi_1(\mathbb{A}^1_k) \) and \( p \) divides \(|G|\).

**Corollary 3.3.** If \( G \neq 0 \) is a quasi-\( p \) group and \( \sigma \in \mathbb{N} \) \((p \nmid \sigma)\) is sufficiently large, then there exists a \( G \)-Galois cover \( \phi : Y \rightarrow \mathbb{P}^1_k \) branched at only one point with conductor \( \sigma \).
The author obtained a similar result in [9] under the restriction that the Sylow $p$-subgroup of $G$ has order $p$.

**Proof.** By [11] and [3], there exists a $G$-Galois cover $\phi : Y \to \mathbb{P}_k^1$ branched only at $\infty$ whose inertia groups are the Sylow $p$-subgroups of $G$. The result is then automatic from Theorem 3.2.

As another corollary, we show that curves $Y$ of arbitrarily high genus occur for $G$-Galois covers $\phi : Y \to X$ branched at $B$ as long as $p$ divides $|G|$.

**Corollary 3.4.** Suppose $X$ is a smooth projective irreducible $k$-curve and $B \subset X$ is a non-empty finite set of points. Suppose $G$ is a finite quotient of $\pi_1(X - B)$ such that $p$ divides $|G|$. Let $p \subseteq \mathbb{N}$ be the set of genera $g$ for which there exists a $G$-Galois cover $\phi : Y' \to X$ branched only at $B$ with genus($Y') = g$. Then the set $p$ contains an arithmetic progression whose increment depends only on $G$ and $p$.

**Proof.** First we show that the hypotheses on $G$ guarantee the existence of a $G$-Galois cover $\phi : Y \to X$ branched only at $B$ with wild ramification at some point. Let $p(G)$ be the normal subgroup of $G$ generated by all elements of $p$-power order. Let $S \subseteq p(G)$ be a Sylow $p$-subgroup of $G$. Consider the natural morphism $\pi : G \to G/p(G)$. By [4, Lemma 2.4], there exists $F \subseteq G$ which is prime-to-$p$ and normalizes $S$ so that $\pi(F) = G/p(G)$. Let $g_1, \ldots, g_r$ be a minimal set of generators for $G/p(G)$. After possibly replacing $F$ with the subgroup generated by elements $h_1, \ldots, h_r$ where $\pi(h_i) = g_i$, we see that $F$ can be generated by $r$ elements. By Abhyankar's Conjecture [3], $r \leq 2g_X + |B| - 1$ and there exists an $F$-Galois cover $Y_0 \to X$ branched only over $B$. Note that $F$ and $p(G)$ generate $G$. As a result, the $F$-Galois cover $Y_0 \to X$ and $p(G)$ satisfy all the hypotheses of [4, Theorems 2.1 and 4.1]. Let $I_1$ be the inertia group of $Y_0 \to X$ above a chosen point $b \in B$. These theorems allow one to modify the cover $Y_0 \to X$ to get a new $G$-Galois cover $\phi : Y \to X$ branched only at $B$ so that the inertia above $b$ is $I = I_1S$. Since $p$ divides $|G|$, it follows that $S$ is non-trivial and so $\phi$ is wildly ramified above $b$.

Let $g_Y$ be the genus of $Y$. The inertia group $I$ is of the form $P \rtimes \mu_m$ for some $P \subset S$. Suppose $|P| = p^r$. Let $\sigma$ be the conductor of $\phi$ above $b$. Let $n$ be the fixed integer $|G|(1 - 1/p^n)\sigma/2$. Let $s$ be such that $p \nmid s$, $s > m\sigma$, and $s \equiv s_i \bmod m$. By Theorem 3.2, it is possible to deform $\phi$ to produce another curve $\phi' : Y' \to X$ branched only at $B$ with larger genus $g_Y' = g_Y - n + |G|(1 - 1/p^n)s/2m$. The set of $g_Y'$ realized in this way clearly contains an arithmetic progression.

By the congruence condition on $s$, one can increase $s$ only by a multiple $s'm$ of $m$, which causes the genus to increase by $|G|(1 - 1/p^n)s'/2$. But one has to remove $(1/p)$th of these values since the integer $s + s'm$ will be divisible by $p$ exactly $(1/p)$th of the time. So the set $p$ contains $p - 1$ arithmetic progressions with increment $p|G|(1 - 1/p^n)/2$.

**Remark 3.5.** The proportion of the set $p$ in $\mathbb{N}$ is at least $2(p^a - p^{a-1})/|G|(p^a - 1)$ for some $a \geq 1$ such that the center of $S$ contains a subgroup $A \simeq (\mathbb{Z}/p)^a$. This lower
bound is approximately $2/|G|$ for large $p$. It is realized when $X \simeq \mathbb{P}^1_k$, $B = \{\infty\}$ and $G = \mathbb{Z}/p$. To see this, note that $\mathbb{Z}/p$-covers of the affine line correspond to Artin-Schreier equations $y^p - y = f(x)$ where the degree $j$ of $f(x)$ is prime-to-$p$. Such a curve has genus $(p - 1)(j - 1)/2$. It follows that the proportion of genera which occur in this case is exactly $2/p$. But in general, we expect that this lower bound is not optimal. For example, we expect that this proportion equals $2/p$ whenever $G$ is an abelian $p$-group.

The following corollary shows that the the structure of Hurwitz spaces for wildly ramified covers will be vastly different from those of tamely ramified covers.

**Corollary 3.6.** For any smooth projective irreducible $k$-curve $X$ and any non-empty finite set of points $B \subset X$ and any finite quotient of $\pi_1(X - B)$ so that $p$ divides $|G|$, a Hurwitz space for $G$-Galois covers $\phi : Y \to X$ branched at $B$ will have infinitely many components.

**Proof.** The proof is immediate from Corollary [3.4] since two covers with different genus cannot correspond to points in the same component of a Hurwitz space. \[ \Box \]

### 4 Example: Inertia $\mathbb{Z}/p^e$.

In this section, we study $\mathbb{Z}/p^e$-Galois covers using class field theory. We give an example of Proposition [2,7] and of singular deformations.

**Definition 4.1.** A sequence $\sigma_1, \ldots, \sigma_e$ is $p^e$-admissible if $\sigma_i \in \mathbb{N}^+$, $p \nmid \sigma_1$ and for $1 \leq i \leq e - 1$, either $\sigma_{i+1} = p\sigma_i$ or $\sigma_{i+1} > p\sigma_i$ and $p \nmid \sigma_{i+1}$.

For convenience, we include the proof of the following classical lemma, [12].

**Lemma 4.2.** If $\hat{\phi} : \hat{Y} \to U_k$ is a $\mathbb{Z}/p^e$-Galois cover, then the upper jumps $\sigma_1, \ldots, \sigma_e$ of its ramification filtration are $p^e$-admissible. For any $p^e$-admissible sequence $\Sigma$, there exists a $\mathbb{Z}/p^e$-Galois cover $\phi : Y \to X$ branched at $B$ with upper jumps at the indices in $\Sigma$.

**Proof.** By the Hasse-Arf Theorem, $\sigma_i \in \mathbb{N}^+$. Since $\sigma_1 = j_1$, we see that $p \nmid \sigma_1$. Suppose $k((u)) \to L$ is the $p^e$-Galois field extension corresponding to $\hat{\phi}$. Note that for $\sigma_i < n \leq \sigma_{i+1}$, the $n$th ramification group $I^n$ in the upper numbering equals $p^i\mathbb{Z}/p^e$. Denote by $U^n$ the unit group $(1 + u^n k[[u]]) \subset k[[u]]^*$. By local class field theory, there is a reciprocity isomorphism $\omega : k((u))^*/NL^* \to \mathbb{Z}/p^e$ so that the image of $U^n$ under $\omega$ equals $I^n$, [13, Chapter XV].

First we show that $\sigma_{i+1} \geq p\sigma_i$. There is some $1 + t^{\sigma_i} h \in U^{\sigma_i}$ whose image under $\omega$ generates $p^{e-1}\mathbb{Z}/p^e$. Thus the image of $(1 + t^{\sigma_i} h)^p \equiv 1 + p^{\sigma_i} h^p \in U^{p\sigma_i}$ generates $p^{e-1}\mathbb{Z}/p^e$. Thus $p^i\mathbb{Z}/p^e \subset I^{p\sigma_i}$, which implies $\sigma_{i+1} \geq p\sigma_i$.

Next suppose $p|\sigma_{i+1}$ and write $\sigma_{i+1} = p(\sigma_i + c)$ for some $c \in \mathbb{N}$. The image of $1 + t^{p(\sigma_i+c)} \in U^{\sigma_{i+1}}$ must generate $p^{i}\mathbb{Z}/p^e$ so the image of $1 + t^{\sigma_i+c}$ must generate $p^{i-1}\mathbb{Z}/p^e$. Thus $1 + t^{\sigma_i+c} \in U^{\sigma_i}$ which implies $c = 0$.  

15
Finally, for any \( p^e \)-admissible sequence \( \{\sigma_1, \ldots, \sigma_e\} \) we define a homomorphism \( U^1 \to \mathbb{Z}/p^e \) as follows: if \( p \nmid c \) and \( \sigma_1 < c \leq \sigma_{i+1} \), then \( 1 + p^ec \mapsto p^e \sigma_i \in \mathbb{Z}/p^e \). Since \( U^1 \) is isomorphic to the abelianization of the fundamental group of \( k((u)) \), it follows that there exists a \( \mathbb{Z}/p^e \)-Galois cover \( \hat{\phi} : Y \to U_k \). The upper jumps of \( \hat{\phi} \) are the given sequence since \( I^n \neq I^{n+1} \) if and only if \( n = \sigma_i \) for some \( i \).

We define a partial ordering on the set of \( p^e \)-admissible sequences as follows.

**Definition 4.3.** Suppose \( \Sigma \) and \( \Sigma' \) are two \( p^e \)-admissible sequences given by \( \sigma_1, \ldots, \sigma_e \) and \( \sigma'_1, \ldots, \sigma'_e \) respectively. Then \( \Sigma' > \Sigma \) if \( \sigma'_i > \sigma_i \) for \( 1 \leq i \leq e \).

The \( p^e \)-admissible sequence which is smaller than all others is \( \{1, p, p^2, \ldots, p^{e-1}\} \).

In the following example, we give a computational proof of Proposition 2.7 in the case that \( m = 1 \) and \( \mathcal{P} = \mathbb{Z}/p^2 \). We note that, even in this simple case, the equations are quite complicated.

**Example 4.4.** Suppose \( \mathcal{P} = \mathbb{Z}/p^2 \) and \( A = \mathbb{Z}/p \). Choose \( j \in \mathbb{N}^+ \) with \( p \nmid j \). By Lemma 1.2 there exists a \( \mathcal{P} \)-Galois cover \( \hat{\psi} : Y \to X \) of germs of \( k \)-curves with upper jumps \( \sigma_1 = j \) and \( \sigma_2 = pj \). Furthermore, no conductor smaller than \( pj \) can occur for a \( \mathcal{P} \)-Galois cover with \( \sigma_1 = j \). By Herbrand’s formula, the upper jumps of \( \hat{\psi} \) are \( j_1 = j \) and \( j_2 = (p^2 - p + 1)j \).

After some changes of coordinates, the equation for the \( \mathbb{Z}/p \)-Galois quotient \( \overline{\phi} : \overline{Y} \to \overline{X} \) can be given generically by \( y_1^p - y_1 = x^{-j} \). Note that there is a natural valuation \( \text{val} \) on the fraction field \( \overline{K} = k((x))[y_1]/((y_1^p - y_1 - x^{-j}) \mathcal{V}) \) and \( \text{val} \) is determined by its isomorphism class as a \( \mathbb{Z}/p \)-Galois cover with \( \sigma_1 = j \). By Herbrand’s formula, the lower jumps of \( \overline{\phi} \) are \( j_1 = j \) and \( j_2 = (p^2 - p + 1)j \).

The \( \mathbb{Z}/p \)-Galois cover \( \psi_\alpha \) is given by an equation \( v^p - v = g(x) \) for some \( g(x) \in k((x)) \). Let \( s \) be the degree of \( x^{-1} \) in \( g(x) \). By Lemma 2.4 the cover \( \overline{\phi}^\alpha \) is determined by its \( \mathbb{Z}/p \)-Galois subcover \( W \to \overline{Y} \) which is given by the equation \( w^p - w = f(y_1, x) + g(x) \). By Lemma 2.3 any \( \mathcal{P} \)-Galois cover dominating \( \overline{\phi} \) is of this form for some \( g(x) \in k((x)) \).

We now give an explicit proof of Proposition 2.7 in this case. Namely, we show that the upper jumps of \( \overline{\phi}^\alpha \) are \( \sigma_1 \) and \( \max\{s, \sigma_2\} \). The first upper jump is \( \sigma_1 \) since \( \overline{\phi}^\alpha \) dominates \( \overline{\phi} \). Let \( J \) be the last lower jump of \( \overline{\phi}^\alpha \). Recall that \( J \) is the prime-to-\( p \) valuation of \( f(y_1, x) + g(x) \). Note that \( x^{-s} = (y_1^p - y_1)^{s/j} = y_1^{ps/j}(1 - y_1^{-p})^{s/j} \). So

\[
x^{-s} = y_1^{ps/j}(1 - y_1^{-(p-1)s/j}) + \ldots = y_1^{ps/j} - y_1^{ps/j-(p-1)s/j} + \ldots.
\]

We can modify the equation for \( W \to \overline{Y} \) by adding \( -y_1^{ps/j} + y_1^{s/j} \) without changing its isomorphism class as a \( \mathbb{Z}/p \)-Galois cover of its jump. The next term in the above equation indicates that the lower jump \( J \) of the cover \( w^p - w = f(y_1, x) + g(x) \) equals \( \max\{-\text{val}(y_1^{ps/j-(p-1)s/j}), -\text{val}(f(y_1, x))\} \). (It cannot be smaller since the valuation of \( f(y_1, x) \) is minimal.) So \( J = \max\{ps - j(p - 1), j_2\} \). By Herbrand’s formula, the conductor of \( \overline{\phi}^\alpha \) equals \( \max\{s, \sigma_2\} \).
Proposition 4.5. Suppose there exists a \( \mathbb{Z}/p^e \)-Galois cover \( \hat{\phi} : \hat{Y} \to U_k \) of normal connected germs of curves whose upper jumps in the ramification filtration are at the \( p^e \)-admissible sequence \( \Sigma \). Suppose \( \Sigma' > \Sigma \) is a \( p^e \)-admissible sequence. Then there exists a singular deformation \( \hat{\phi}_\Omega : \hat{\mathcal{Y}} \to \hat{U}_\Omega \) whose generic fibre has ramification filtration \( \Sigma' \).

Proof. The proof is by induction on \( e \). If \( e = 1 \), the proof follows by Proposition 3.1. If \( e > 1 \), choose \( A \subset I_{\sigma} \) to be a subgroup of order \( p \). The \( \mathbb{P}/A \)-Galois quotient \( \hat{\phi} \) has upper jumps \( \sigma_1, \ldots, \sigma_{e-1} \). By the inductive hypothesis, there exists a deformation \( \hat{\phi}_\Omega : \hat{\mathcal{Y}}_\Omega \to \hat{U}_\Omega \) whose generic fibre is a \( \mathbb{Z}/p^{e-1} \)-Galois cover of normal connected curves whose branch locus consists of only the \( K \)-point \( \xi_K = \xi_\Omega \times_\Omega K \) over which it has upper jumps \( \sigma'_1, \ldots, \sigma'_{e-1} \).

By [1, X, Theorem 5.1], there exists a \( \mathbb{P} \)-Galois cover \( \hat{\phi}'_\Omega \) dominating \( \hat{\phi}_\Omega \). Choose \( \hat{\phi}'_\Omega \) to have minimal conductor \( s' \) among all such covers dominating \( \hat{\phi}_\Omega \). By Lemma 4.2, \( s' = ps'_{e-1} \). The restriction of \( \hat{\phi}'_\Omega \) to \( U_k \) has conductor at most \( s' \). This restriction differs from \( \phi \) by an element \( \alpha \in \text{Hom}(\pi_1(U_\Omega - \xi_\Omega), A) \). By Proposition 2.7, \( \alpha \) has conductor at most \( \max\{s', \sigma_e\} \).

Let \( \hat{\phi}_e \) be the cover \( \hat{\phi}'_\Omega \) modified by \( \alpha \). By Proposition 2.7 and by minimality of \( s' \), the conductor \( \sigma \) of \( \hat{\phi}_e \) satisfies \( s' \leq \sigma \leq \max\{s', \sigma_e\} \). Since \( \Sigma' > \Sigma \) is \( p^e \)-admissible, \( \sigma'_e \geq \sigma_e \) and \( \sigma'_e \geq ps'_{e-1} = s' \) (with \( p \nmid \sigma'_e \) if equality does not hold). We apply Proposition 3.1 with \( s = \sigma'_e \) to increase the conductor. The conclusion is that there exists a deformation \( \hat{\phi}_\Omega : \hat{\mathcal{Y}} \to \hat{U}_\Omega \) whose generic fibre has inertia \( \mathbb{Z}/p^e \) and conductor \( \sigma'_e \). \qed
