Application of algebraic combinatorics to finite spin systems with dihedral symmetry

Abstract

Properties of a given symmetry group $G$ are very important in investigation of a physical system invariant under its action. In the case of finite spin systems (magnetic rings, some planar macromolecules) the symmetry group is isomorphic with the dihedral group $D_N$. In this paper group-theoretical ‘parameters’ of such groups are determined, especially decompositions of transitive representations into irreducible ones and double cosets. These results are necessary to construct matrix elements of any operator commuting with $G$ in an efficient way. The approach proposed can be useful in many branches of physics, but here it is applied to finite spin systems, which serve as models for mesoscopic magnets.

1 Introduction

One of standard ways of quantum magnets modeling is to consider a finite set of \(N\) nodes carrying spins \(s_j\), \(1 \leq j \leq N\), with a spin number \(s\). At present such models are also used to investigate properties of magnetic macromolecules as Mn_{12}acetate \([4]\). The so-called Ising states or configurations, i.e. tensor products

\[
\mu = |m_1, m_2, \ldots, m_N\rangle, \quad -s \leq m_j \leq s, \tag{1}
\]

of one-spin states \(|m_j\rangle\) form a natural basis \(B\) of the quantum space of states \(L\) with the dimension \(\dim L = (2s + 1)^N\). In a general case, however, these states are not eigenvectors of the Heisenberg-like Hamiltonians. Therefore, it is necessary to solve an eigenproblem with \(\dim L\) equations what, even using contemporary computers, is almost impossible for \(N \approx 30\) and \(s > 1\). This is especially important when one wants to investigate spin correlations in the ground state and some of the first excited states of antiferromagnetic systems, since many methods allow to determine eigenvalues, but it is much more difficult to find eigenvectors. Among others, it is caused by the numerical instability of necessary algorithms in the case of a very large number of linear equations \([2]\).

The problem is partially solved by taking into account operators commuting with a given Hamiltonian: \(e.g.\) the \(z\)-th component of the total spin \(S^z\) and irreducible representations of the Hamiltonian symmetry group \([3, 4]\). If the spin interactions are isotropic, then also the total spin number may be taken into account. However one has to find solutions of a set of homogeneous linear equations arising from the eigenproblem for \(S^2\) (in finite spin system eigenvalues of \(S^2\) are known). In many interesting cases, for example investigating the ground state of bipartite antiferromagnets, these solutions can be found exactly if one is able to cope with very large integers. Such tools are provided by multiple (or arbitrary) precision libraries like the GNU Multiple Precision Arithmetic Library (GMP or GNU MP in short) written and developed by T. Granlund \([5]\). However, such procedures work efficiently if the matrix of an operator (the squared total spin \(S^2\) or the Hamiltonian \(\mathcal{H}\) in the presented considerations) are written in the symmetry adapted basis.

The considerations presented are illustrated by examples related with finite spin models, but a similar method can be applied in any case when:

- the space of states \(L\) is spanned over orthonormal vectors \(\{B\}\), \(i.e.\) it is the \(N\)th tensor power of the \(n\)-dimensional one-particle space;

- the considered operator \(\mathcal{H}\), acting in \(L\), commutes with a given permutation representation \(P\) of a group \(G\) (the Hamiltonian symmetry group).

Let a given group \(G\) permutes vectors of a (finite) basis \(B\) of the quantum state space \(L\). In the previous paper \([4]\) general formulas for vectors of the irreducible basis and
The labeling scheme for the ground state energy of infinite linear antiferromagnets is approximated from below and one deals with bipartite antiferromagnets \([1]\), so the case of \(N\) important, however the other case (groups with the following generation relations \([8]\):

\[
U_j, \quad 0 \leq j < N,
\]

are elementary ‘bricks’ for finite space groups \([7]\). However, groups \(D_{Nh}\) isomorphic and the abstract group \(D_N\) should be considered. These groups are important, for example, constructing symmetry coordinates of vibrating molecules or crystals, but in the case of spin models the action of \(\sigma_h\) is trivial. Considering planar molecules one should introduce groups \(C_{Nh}\), which are elementary ‘bricks’ for finite space groups \([8]\). However, groups \(D_N\) and \(C_{Nh}\) are isomorphic and the abstract group \(D_N\) is considered as a representative of isomorphic groups with the following generation relations \([8]\):

\[
D_N = \langle C_N, U_0 \rangle, \quad C_N^2 = U_0^2 = (C_N U_0)^2 = E, \quad 0 \leq j < N. \tag{2}
\]

The dihedral group \(D_N\) consists of \(2N\) elements: \(N\) powers of the \(N\)-fold rotation \(C_N\) and perpendicular to it the twofold rotations \(U_j = C_N^j U_0, 0 \leq j < N\). It is easy to write down general formulas for multiplication (all calculations are done mod \(N\)):

\[
C_N^j C_N^k = C_N^{j+k}, \quad C_N^j U_k = U_{j+k}, \quad U_j C_N^k = U_{j-k}, \quad U_j U_k = C_N^{j-k}. \tag{3}
\]

The labeling scheme for \(N = 6\) is presented in Fig. \([\text{Fig. 1}]\).

The dihedral groups are considered in Sec.\([3]\); there are many differences between cases of \(N\) odd and even, so the results are presented separately. In many actual applications one deals with bipartite antiferromagnets \([1]\), so the case of \(N\) even seems to be more important, however the other case (\(N\) odd) is discussed for three, at least, reasons: (i) the ground state energy of infinite linear antiferromagnets is approximated from below and

\[
\text{Figure 1: Numbering of ring nodes and elements of the group } D_6 \text{ (the six-fold axis } C_6 \text{ is denoted by the full hexagon)}
\]
above by those obtained in the cases of even- and odd-sized rings, respectively ⁴; (ii) there are still some open problem related with linear ferromagnets (e.g. critical exponents near \( T = 0 \) K ⁹); in this case the parity of \( N \) is (almost) irrelevant; (iii) the presented considerations and results are more complete. In Sec. 3 a partial solution for six spins \( s = 1 \) (a ring invariant under \( D_6 \)) is discussed. The paper ends with some conclusions.

2 Dihedral groups \( D_N \)

Let us recall the formulas obtained in the previous paper ⁶ to check what group properties should be determined. The irreducible basis consists of vectors \( |U \mu; \Gamma r\gamma \rangle \), where:

- \( U \subseteq G \) is a subgroup of \( G \) representing a conjugacy class \( \tilde{U} \);
- \( \mu \) is a representative of an orbit of type \( U \);
- \( \Gamma \) is an irreducible representation (an irrep) of \( G \), the repetition index \( r \) distinguishes copies of \( \Gamma \) and \( \gamma = 1, 2, \ldots, [\Gamma] \) labels vectors of \( \Gamma \).

The orbit \( G(\mu) \) can be identified more precisely if one introduces a label denoting a non-ordered partition \( [k] \) such that \( \mu \in B[k] \). Note that \( [k] \) identifies also the magnetization \( M \). However, the formula for vectors of the irreducible basis does not depend on \( [k] \) and is given as ³

\[
|U \mu; \Gamma r\gamma \rangle = \sum_{j=1}^{[G/U]} b_j^{\Gamma r\gamma}(U)|U \mu g_j \rangle,
\]

where the elements \( g_j, 1 \leq j \leq [G/U] \) with \( g_1 = E \), represents the left cosets \( gU \in G/U \). The coefficients \( b_j^{\Gamma r\gamma} \), determining a unitary transformation, can be expressed by matrix elements of the irrep \( \Gamma \) and the reduction coefficients \( A_{\alpha\beta}^{UT} \):

\[
b_j^{\Gamma r\gamma}(U) = \left( \frac{|\Gamma U|}{|U|} \right)^{1/2} \sum_{\beta=1}^{[\Gamma]} \Gamma^*_{\alpha\beta}(g_j)(A_{\beta\gamma}^{UT})^*.
\]

Matrix elements of any operator, e.g. a Hamiltonian \( \mathcal{H} \), commuting with all \( P(g) \) are grouped in blocks labeled by \( \Gamma \) and depend only on \( U, \mu \) and \( r \):

\[
h_{U,\mu r,\nu s}(\Gamma) = \left( \frac{|U|}{|V|} \right)^{1/2} \sum_{j=1}^{[G/U]} (U \mu g_j |\mathcal{H} V \nu E \rangle B_{rs}^{\nu \gamma}(g_j),
\]

where

\[
B_{rs}^{\nu \gamma}(g_j) = \sum_{\alpha,\beta} (A_{\alpha s}^{VT})^* \Gamma_{\alpha\beta}(g_j) A_{\beta r}^{UT}.
\]

It is helpful to consider non-ordered partitions \( [k] \), because matrix elements are equal to zero if partitions \( [k] \) and \( [k'] \) are not joined by an edge in the graph introduced in Sec. 5.
of the previous paper \footnote{[3]}. Introducing the notion of double cosets $VgU$ this formula can be modified and written as:

$$h_{U\mu r, V\nu s}(\Gamma) = (|U||V|)^{-1/2} \sum_{d=1}^{[V\backslash G/U]} |Vg_dU|B_{rs}^{UV}(g_d)\langle U\mu g_d|H|V\nu E\rangle,$$

(8)

where elements $g_d$ represent double cosets $Vg_dU$, or orbits of the natural action $V(G/U)$.

All structures appearing in these formulas (cosets, irreps, reduction coefficients etc.) in the case $G = D_N$ are discussed in the following subsections.

### 2.1 Classes and irreps

The multiplication rules (3) in the dihedral group $D_N$ lead immediately to classes of conjugated elements:

- **$N$ odd:** $\{E\}, \{C^j_N, C^{N-j}_N\}, j = 1, 2, \ldots, \frac{N-1}{2}, \{U_0, U_1, \ldots, U_{N-1}\}$
- **$N$ even:** $\{E\}, \{C^j_N, C^{N-j}_N\}, j = 1, 2, \ldots, \frac{N}{2} - 1,$

$$\{C_2 = C_N^{N/2}\}, \{U_0, U_2, \ldots, U_{N-2}\}, \{U_1, U_3, \ldots, U_{N-1}\}.$$

Therefore, there are $(N + 3)/2$ classes (and irreps) for $N$ odd and $N/2 + 3$ for $N$ even. In the special cases, $N = 1, 2$, the groups $D_N$ are Abelian.

In both cases, $N$ odd and even, there are two one-dimensional irreps, denoted $A_1$ (the unit irrep) and $A_2$, with characters

$$\chi^{A_1}(g) = 1, \quad \forall g \in D_N; \tag{9}$$

$$\chi^{A_2}(C^j_N) = 1, \quad \chi^{A_2}(U_j) = -1, \quad j = 0, 1, \ldots, N - 1. \tag{10}$$

For $N$ even there are two more one-dimensional irreps, denoted $B_1$ and $B_2$, with characters ($j = 0, 1, \ldots, N - 1$)

$$\chi^{B_1}(C^j_N) = (-1)^j; \quad \chi^{B_1}(U_j) = (-1)^j; \tag{11}$$

$$\chi^{B_2}(C^j_N) = (-1)^j; \quad \chi^{B_2}(U_j) = -(-1)^j. \tag{12}$$

Note that the element $C_2 = C_N^{N/2}$ behaves in different ways for $N = 4M$ and $N = 4M + 2$. In the first case one obtains $\chi^{B_1}(C_2) = \chi^{B_2}(C_2) = 1$, whereas in the second case this character equals $-1$.

The other irreps, denoted $E_l, l = 1, 2, \ldots, N_E$, are two-dimensional; there are $N_E = (N-1)/2$ and $N_E = N/2 - 1$ such irreps for $N$ odd and even, respectively. Their characters are given by the same formulas

$$\chi^{E_l}(C^j_N) = 2\cos(2\pi j l/N), \quad \chi^{E_l}(U^j) = 0. \tag{13}$$
To complete the presentation, matrices of the representations $E_l$ in the standard basis \{|Ex\rangle, |Ey\rangle\} for the generators $C_N$ and $U_0$ are written down:

$$E_l(C_N) = \begin{pmatrix} \cos(2\pi jl/N) & -\sin(2\pi jl/N) \\ \sin(2\pi jl/N) & \cos(2\pi jl/N) \end{pmatrix}, \quad E_l(U_0) = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \quad (14)$$

### 2.2 Subgroups and conjugated subgroups

Let $N$ be written as a product of $r$ different primes $p_i$:

$$N = \prod_{i=1}^{r} p_i^{\alpha_i}, \quad \alpha_i > 0.$$ 

Then there are $D = \prod_{i=1}^{r} (\alpha_i + 1)$ different divisors $k$ of $N$, each of them can be written as ($k = 1$ corresponds to all $\beta_i = 0$)

$$k = \prod_{i=1}^{r} p_i^{\beta_i}, \quad 0 \leq \beta_i \leq \alpha_i.$$

The first family of subgroups consists of the cyclic groups $C_k$, where $k$ is a divisor of $N$. These groups are generated by elements $C^\kappa_N$, where $\kappa = N/k$ is the so-called co-divisor of $k$. For $k = 1$ one obtains the group $C_1 = \{E\}$, which has no generators; in this case $\kappa = N$. Each subgroup $C_k$ contains $k$ elements in the form $C^{\rho \kappa}_N \equiv C_p^\rho$, $p = 0, 1, \ldots, k - 1$. Since these groups are normal divisors of $D_N$, then each $C_k$ is conjugated to itself only.

The second family of subgroups is formed by the dihedral groups $D_k$. However, for each $k$, i.e. for each generator $C^\kappa_N$, one has freedom in a choice of two-fold generator $U_j$. The subgroups isomorphic to $D_k$ are generated by $C^\kappa_N$ and one of the rotations $U_0, U_1, \ldots, U_{\kappa-1}$. These subgroups will be denoted hereafter as

$$D^q_k = \langle C^\kappa_N, U_q \rangle, \quad q = 0, 1, \ldots, \kappa - 1.$$ 

Each of these groups contains, except for the rotations $C^{\rho \kappa}_N$, twofold axes $U_{q+p\kappa}$, $p = 0, 1, \ldots, k - 1$. In the case of odd $\kappa$ these elements belong to the same conjugacy class, so all subgroups $D^q_k$ are conjugated. This conjugacy class is represented by $D_k = \langle C^\kappa_N, U_0 \rangle$. When $\kappa$ is even, then all two-fold $U_j$ rotations in the subgroup $D^q_k$ have indices with the same parity. Therefore, there are two classes of conjugated subgroups: the first is represented by $D^0_k = \langle C^\kappa_N, U_0 \rangle$ and the second by $D^1_k = \langle C^\kappa_N, U_1 \rangle$. If $N$ is even then it can be written as $2^a N'$, where $N'$ is odd. In the same way all divisors $k$ of $N$ can be written as $2^{\beta} k'$. If $\beta = \alpha$ then corresponding $\kappa = N'/k'$ is odd and, therefore, there is only one class of conjugated subgroups $D_k$. Two separated classes, $D^0_k$ and $D^1_k$, are obtained in the other cases, i.e. when $\beta < \alpha$ and $\kappa = 2^{\alpha-\beta} N'/k'$. Let $D' = D/\langle \alpha + 1 \rangle$ be the number of divisors of $N'$ ($D' = D$ if $N$ is odd) then:

- there are $D'$ classes of dihedral subgroups in type $D_k$;
• in each type $D^0_k$ and $D^1_k$ there are $\alpha D'$ classes of dihedral subgroups.

Therefore, there are $(\alpha+1)D'$ cyclic subgroups and $(2\alpha+1)D'$ conjugacy classes of dihedral subgroups. The lattice of conjugated subgroups for the group $D_6$ is presented in Fig. 2.

The theorem presented in Sec. 2.3 of the previous paper [3] immediately excludes some classes of subgroups if vectors of the considered basis are mappings, as in the case of magnetic configurations. The first excluded subgroup is the cyclic group $C_N$, since there is only one orbit $X = \{0,1,\ldots,N-1\}$, so $\Pi_j \Sigma_{X_j} = \Sigma_X$ and $P(D_N) \cap \Sigma_X = P(D_N) \neq P(C_N)$. In the case of $N$ even two other subgroups are excluded: the dihedral subgroup $D^1_{N/2}$ and the cyclic subgroup $C_{N/2}$. In the first case only one orbit $X$ is again obtained, whereas $C_{N/2}$ decomposes $X$ into subsets $X_0$ and $X_1$ containing nodes with even and odd indices, respectively. Then one obtains $P(D_N) \cap (\Sigma_{X_0} \times \Sigma_{X_1}) = P(D^0_{N/2}) \neq P(C_{N/2})$. Therefore, these subgroups can be omitted in the further considerations of spin configurations. For example, when $N = 6$ subgroups $C_6$, $D^1_3$, and $C_3$ are excluded.

2.3 Cosets

For each representative $U$ of a class of conjugated subgroups $\bar{U}$ left coset representatives have to be chosen and fixed. The index $|D_N|/|D_1| = \lambda$ and the rotations $C^i_U$, $j = 0,1,\ldots,\lambda - 1$ will play this role. In the case of cyclic subgroups $C_k$ one needs additional $\lambda$ representatives. They can be chosen as $U_j$, $j = 0,1,\ldots,\lambda - 1$. The choice of coset representatives is fixed in the further considerations.

Considering double cosets $V \backslash D_N / U$ we determine at first their number in different cases using results presented in Sec. 3 of the previous work [3]. If both $U$ and $V$ are cyclic
then only classes containing rotations $C_N^j$ have to be taken into account and one obtains

$$|C_K \backslash D_N / C_l| = 2 \gcd (\kappa, \lambda) = 2 \chi,$$

where ‘gcd’ denotes the greatest common divisor and $\kappa = N/k, \lambda = N/l$ are co-divisors of $k$ and $l$, respectively. Note that for mutually prime co-divisors $\kappa, \lambda$ there are two double cosets only: one contains rotations $C_N^j$, whereas the second — elements $U_j$. If $V = D_k$ (or $U = D_l$ and $V = C_k$), then the only change is the order of one subgroup, so the result is

$$|C_K \backslash D_N / D_l| = |D_K \backslash D_N / C_l| = \chi.$$

If both subgroups are dihedral then the cases of odd and even $N$ have to be considered separately. Moreover, in the case of even $N$ a dihedral subgroup $D_k$ can be in one of three types: $D_0^k, D_1^k$ or $D_k$. In the first case it contains elements $U_j$ with even indices $j$, in the second case all $j$’s are odd and in the last case odd and even indices $j$ are present. The final results are as follows:

- $N$ odd
  $$|D_k \backslash D_N / D_l| = (\chi + 1)/2;$$

- $N$ even
  $$|D_0^k \backslash D_N / D_l| = |D_1^k \backslash D_N / D_l| = (\chi + 2)/2;$$
  $$|D_0^k \backslash D_N / D_l| = \chi/2;$$
  $$|D_0^l \backslash D_N / D_l| = |D_1^l \backslash D_N / D_l| = |D_k \backslash D_N / D_l| = (\chi + 1)/2.$$

The above presented formulas are symmetric, i.e. the subgroups $U$ and $V$ can be transposed. However, in a general case a set of double cosets $V \backslash G / U$ is not symmetric, i.e. it differs from the set $U \backslash G / V$ (they have the same orders only). The same can be said about representatives $g_d$ of double cosets. Therefore, both cases should be considered separately and for each pair $V, U$ we obtain two sets of double coset representatives. On the other hand, the operators considered are Hermitian, so $h_{U \mu r, V \nu s} = h_{V \nu s, U \mu r}^*$ and, therefore, it is enough to determine one element of each pair. Nevertheless, for the sake of completeness all cases are considered below.

Since the cyclic subgroups are self-conjugated, then for a given $V$ all double cosets $VgC_l$ have the same order (see Eq. (13) in [3]):

$$|VgC_l| = |C_lgV| = \frac{l|V|}{|V \cap C_l|}.$$

The stabilizer in the denominator for $V = D_k$ or $C_k$ is equal to $C_{\gcd(k,l)}$. Therefore,

$$|C_kgD_l| = |D_kgC_l| = 2|C_kgC_l| = 2 \frac{k l}{\gcd(k,l)} = 2 \text{lcm}(k, l),$$
The following four cases have to be discussed:

1. \( U = D_1^0, \, V = D_1^0 \): It follows from the first formula that cosets \( C_k C_N^j D_t^0 \) and \( C_k C_N^{\chi-j} D_t^0 \) are merged. There is one fixed point, namely \( j = 0 \). If \( \chi \) is even then there is another fixed point \( j = \chi/2 \).

2. \( U = D_1^1, \, V = D_1^1 \): In this case the last formula should be used so the results are the same as above.

where ‘\( \text{lcm} \)’ denotes the least common multiplicity. This result agrees with the above presented formulas, since \( \chi = \gcd(k, \lambda) = N/h \) with \( h = \text{lcm}(k, l) \). These double cosets are represented by \( g_d = C_N^j \) with \( j = 0, 1, \ldots, \chi - 1 \) if one subgroup is cyclic. If both subgroups are cyclic, then the next \( \chi \) representatives are \( g_d = U_j, \, 0 \leq j < \chi \). The cardinality of double cosets just obtained does not depend on the representative \( g \), so Eq. (8) can be simplified if one of subgroups is cyclic. To shorten the notation let us introduce two symbols: (i) the product \( B_{rs}^{UVT}(g_d)(U g_d | H | V \nu E) \) is denoted as \( f(g_d) \) \((U, \, V, \, \Gamma \, \text{etc.} \) are omitted, but they can be easily determined from the context) and (ii) \( \text{sd}(k, l) = \text{lcm}(k, l) \). Using these symbols one can write

\[
\begin{align*}
    h_{C_{l \mu r, C_N \nu s}}(\Gamma) & = \text{sd}(k, l)^{1/2} \sum_{d=0}^{\chi-1} f(C_N^d) + f(U^d), \quad (15) \\
    h_{D_{l \mu r, C_N \nu s}}(\Gamma) & = h_{C_{l \mu r, D_N \nu s}}(\Gamma) = (2\text{sd}(k, l))^{1/2} \sum_{d=0}^{\chi-1} f(C_N^d). \quad (16)
\end{align*}
\]

The most complicated is the case when both subgroups \( U \) and \( V \) are dihedral, because double cosets obtained may have different lengths and there are three different values of the number of double cosets. In fact, we are not interested in their detailed structure, but we have to know the number of representatives \( g \) of left cosets \( gU \) contained in a double coset \( V g_d U \). The appropriate rules can be derived if one notices that the action of \( V = D_k \) on the set of left cosets \( D_N/D_t \) can be performed in two steps: (i) the action of the cyclic subgroup \( C_k \subset D_k \) considered above and (ii) the action of the generator \( U_0 \) or \( U_1 \), depending on the type of \( V \). The other elements \( U_{q+p\kappa}, \, q = 0, 1, \, 0 < p < k \), do not yield new results since \( U_{q+p\kappa} = U_q C_N^{(k-p)\kappa} \) and the action of \( C_N^{(k-p)\kappa} \) has been already taken into account. After the first step we have at hand \( \chi \) orbits represented by \( C_N^j \), \( 0 \leq j < \chi \). Each coset \( C_k C_N^j D_t \) contains also \( \lambda \lambda = \lambda / \chi \) representatives of left cosets \( gD_t \) in the form \( C_N^{\alpha+j} \), \( 0 \leq r < \lambda \). From the multiplication rule (3) we obtain \((h = N/\chi)\):

\[
\begin{align*}
    U_0 C_N^j & = C_N^{\chi-j} U_{\chi(h-1)} \quad \text{or} \quad U_0 C_N^j = C_N^{\chi-j-1} U_{\chi(h-1)+1}; \\
    U_1 C_N^j & = C_N^{\chi-j+1} U_{\chi(h-1)} \quad \text{or} \quad U_1 C_N^j = C_N^{\chi-j} U_{\chi(h-1)+1}.
\end{align*}
\]

The following four cases have to be discussed:

- **U = D_t^0, V = D_t^0**: It follows from the first formula that cosets \( C_k C_N^j D_t^0 \) and \( C_k C_N^{\chi-j} D_t^0 \) are merged. There is one fixed point, namely \( j = 0 \). If \( \chi \) is even then there is another fixed point \( j = \chi/2 \).

- **U = D_t^1, V = D_t^1**: In this case the last formula should be used so the results are the same as above.

1. The symbol ‘\( \text{sd} \)’ means the symmetric division and has been introduced by analogy to the symmetric difference of sets: \( \text{sd}(k, l) \) is a product of primes, which appear in decomposition of either \( k \) or \( l \); the authors have not found any special name for this symbol in available books on the number theory.
Table 1: Representatives of cosets $gU$ contained in the same double coset $VgU$ for the dihedral group $D_6$ and $U, V = D^0_1, D^1_1, D_2$: underbraced elements belong to the same orbit under the action of the cyclic subgroup $C_2$ of $V = D_2$

| $U$ | $D^0_1$ | $D^1_1$ | $D_2$ |
|-----|--------|--------|-------|
| $D^1_i$ | $\{E\}$ | $\{E, C^0_6\}$ | $\{E\}$ |
|       | $\{C_6, C^0_6\}$ | $\{C_6, C^0_6\}$ | $\{C_6, C^2_6\}$ |
|       | $\{C^2_6, C^4_6\}$ | $\{C^2_6, C^4_6\}$ | $\{C^2_6, C^4_6\}$ |
| $D^0_i$ | $\{E, C^0_6\}$ | $\{E\}$ | $\{E, C^0_6\}$ |
|       | $\{C^2_6, C^4_6\}$ | $\{C_6, C^0_6\}$ | $\{C^0_6\}$ |
|       | $\{C^3_6\}$ | $\{C^3_6\}$ | $\{C^0_6\}$ |
| $D_2$ | $\{E, C^0_6\}$ | $\{E, C^0_6, C^2_6, C^4_6\}$ | $\{E\}$ |
|       | $\{C_6, C^4_6, C^2_6, C^5_6\}$ | $\{C_6, C^4_6\}$ | $\{C_6, C^2_6\}$ |

- $U = D^1_1, V = D^0_1$: Orbits $C_k C^d_N D^1_1$ and $C_k C^d_N D^1_1$ are merged if $j' = -(1 + j) \pmod{\chi}$. The fixed point is obtained for $2j = -1 \pmod{\chi}$, so it is possible for odd $\chi$ only and in this case $j = (\chi - 1)/2$.

- $U = D^0_1, V = D^1_1$: In this case the congruence $j' = 1 - j \pmod{\chi}$ has to be satisfied to merge orbits and the fixed point is obtained for $j = (\chi + 1)/2$, if $\chi$ is odd. In this case it may be more convenient to use $j = 1, 2, \ldots, \chi/2$ for $\chi$ even and $j = 1, 2, \ldots, (\chi - 1)/2, (\chi + 1)/2$ for $\chi$ odd.

In Table 1 all possible cases are presented for $N = 6$ and $U, V = D^0_1, D^1_1, D_2$. Each entry is a set of representatives $g$ of left cosets $gU$, which are contained in the same double coset $VgU$.

Taking into account the results presented above one obtains the following formulas for matrix elements:

$$h_{D^0_1 \mu, D^0_1 \nu s}(\Gamma) = h_{D^1_1 \mu, D^1_1 \nu s}(\Gamma) = \text{sd}(k, l)^{1/2} \left( f(E) + 2 \sum_{d=1}^{\chi/2-1} f(C^d_N) + f(C^\chi/2_N) \right); \quad (17)$$

$$h_{D^0_1 \mu, D^1_1 \nu s}(\Gamma) = 2 \text{sd}(k, l)^{1/2} \sum_{d=1}^{\chi/2} f(C^d_N); \quad \quad (18)$$

$$h_{D^0_1 \mu, D_{k \nu s}}(\Gamma) = h_{D^1_1 \mu, D_{k \nu s}}(\Gamma) = h_{D \mu, D_{k \nu s}}(\Gamma) = \text{sd}(k, l)^{1/2} \left( f(E) + 2 \sum_{d=1}^{(\chi-1)/2} f(C^d_N) \right); \quad (19)$$

$$h_{D^1_1 \mu, D^0_1 \nu s}(\Gamma) = 2 \text{sd}(k, l)^{1/2} \sum_{d=0}^{\chi/2-1} f(C^d_N); \quad \quad (20)$$

10
In the first case we have to distinguish subgroups \(D_r\) where \(\lambda\) is even. The two-dimensional irreps \(E_p\) always appear twice, i.e. \(n(E_p, R^{D_N,C_l}) = 2\) if \(\gcd(p, l) = l\). Since \(p < N/2\) then only subgroups \(C_l\) with \(l < N/2\) lead to decompositions containing \(E_p\).

The dihedral groups \(D_l\) have twice more elements then \(C_l\) then the dimensions of \(R^{D_N:D_l}\) are two times smaller. At first, one can notice that the irrep \(A_2\) does not appear in the appropriate decompositions. The case \(\Gamma = E_p\) is simply, since one obtains

\[
n(E_p, R^{D_N:D_l}) = n(E_p, R^{D_N:C_l})/2 = 1 \quad \text{if} \quad \gcd(p, l) = l.
\]

The irreps \(B_1\) and \(B_2\) (admissible for \(N\) even only) appears depending on the type of the group \(D_l\):

\[
n(B_1, R^{D_N:D_l^0}) = n(B_2, R^{D_N:D_l^1}) = 1.
\]

The results obtained are illustrated in Table 2 for \(N = 6\).

### 2.5 Reduction coefficients

A general formula for the reduction coefficients, see Sec. 2.4 in [1], yields that one-dimensional irreps \(\Gamma\) always lead to trivial reduction coefficients \(A^{UT} = 1\). The indices \(\gamma = 1\) and \(r = 1\) can be omitted. So only the case \(\Gamma = E_p\) has to be considered in more details. The vector of irreducible basis related with the reduction \(E_p \downarrow U\) in this case can be written as

\[
|U E_p r\rangle = A^{U E_p r}_{x r} |E_p x\rangle + A^{U E_p r}_{y r} |E_p y\rangle,
\]

where \(r = 1\) for the dihedral \((D_l)\) and \(r = 1, 2\) for the cyclic \((C_l)\) subgroups \(U\), respectively. In the first case we have to distinguish subgroups \(D_l^0\) and \(D_l^1\). The standard choice of the basis \(\{|E_p x\rangle, |E_p y\rangle\}\) and Eq. (14) yield the matrices:

\[
E_p(U_0) = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad E_p(U_1) = \begin{pmatrix} \cos(2\pi p/N) & \sin(2\pi p/N) \\ \sin(2\pi p/N) & -\cos(2\pi p/N) \end{pmatrix}.
\]
Table 2: Decompositions of transitive representations into irreps for $D_6$ (subgroups are determined by their generators)

| $U$          | $R^{D_6:U}$                      |
|-------------|----------------------------------|
| $C_1 = \{E\}$ | $A_1 \oplus A_2 \oplus B_1 \oplus B_2 \oplus 2E_1 \oplus 2E_2$ |
| $D_0^1 = (U_0)$ | $A_1 \oplus B_2 \oplus E_1 \oplus E_2$ |
| $D_1^1 = (U_1)$ | $A_1 \oplus B_2 \oplus E_1 \oplus E_2$ |
| $C_2 = (C_3^0)$ | $A_1 \oplus A_2 \oplus 2E_2$ |
| $D_2 = (C_3^0, U_0)$ | $A_1 \oplus E_2$ |
| $C_3 = (C_3^0)$ | $A_1 \oplus A_2 \oplus B_1 \oplus B_2$ |
| $D_0^3 = (C_2^0, U_0)$ | $A_1 \oplus B_1$ |
| $D_1^3 = (C_2^0, U_1)$ | $A_1 \oplus B_2$ |
| $C_6 = (C_6)$ | $A_1 \oplus A_2$ |
| $D_6 = (C_6, U_0)$ | $A_1$ |

Therefore, one obtains (for representations $E_p$ appearing in the decompositions of $R^{D_i:D_1}$, i.e. for $\gcd(p, l) = l$):

$$A_x^{D_0^2 E_p} = 1, \quad A_y^{D_0^2 E_p} = 0; \quad A_x^{D_1^2 E_p} = \cos(\varphi/2), \quad A_y^{D_1^2 E_p} = \sin(\varphi/2),$$

where $\varphi = 2\pi p/N = 2\pi p_l/\lambda$ with $p_l = p/l$. The cyclic subgroups yield $r = 1, 2$ and it can be shown that there are no restrictions imposed on the coefficients $A_{\gamma r}^{C_1 E_p}$, as long as they determine orthonormal vectors $|C_1 E_{p1}\rangle, |C_1 E_{p2}\rangle$. The simplest choice is to put

$$A_{x1}^{C_1 E_p} = 1, \quad A_{y1}^{C_1 E_p} = 0; \quad A_{x2}^{C_1 E_p} = 0, \quad A_{y2}^{C_1 E_p} = 1.$$  

Now we have to calculate the coefficients $B_{rs}^{UV \Gamma}(g_j)$ for the representatives of left cosets $g_j U$. Let us start from one-dimensional irreps $\Gamma = A_1, A_2, B_1, B_2$. Since the coefficients $A^{UV\Gamma} = 1$ and $r, s = 1$, then

$$B^{UV\Gamma}(g_j) = \Gamma(g_j) = \chi^{\Gamma}(g_j).$$

Characters of these representations are given by Eqs. (9)–(12). In particular, the unit irrep $A_1$ always yields $B^{UV A_1}(g_j) = 1$.

The two-dimensional irreps $E_p$ appear in decompositions of $R^{D_N:C_1}$ and $R^{D_N:D_i}$ for $l < N/2$ and $p = l p_l$; if $U$ or $V$ is the cyclic subgroup then $E_p$ appears twice. Moreover, there are two types of the dihedral subgroups for $N$ even. It leads to 16 different cases of coefficients $B_{rs}^{UV E_p}$, which will be presented below. We are interested in the coefficients $B_{rs}^{UV E_p}$ when the irrep $E_p$ appears in the decompositions of $R^{D_N:U}$ and $R^{D_N:V}$. Let, as
in Sec. 2.3 \( V = C_k \) or \( D_k \) and \( U = C_l \) or \( D_l \). Then the index \( p \) of the irrep \( E_p \) has to satisfy both conditions: \( p = p_k k \) and \( p = p_l l \). Therefore, \( p = \text{lcm}(k,l)p' = hp' = Np' / \chi \) and \( \varphi = 2\pi p / N = 2\pi p' / \chi \).

Let subgroups \( U, V \) be cyclic. Then both repetition indices \( r, s \) = 1, 2, so there are four different coefficients \( B_{rs}^{UV} E_p(g_j) \). We have chosen elements \( C_N^j \) and \( U_j, j = 0,1, \ldots, \lambda - 1 \) as representatives of the left cosets \( g_j C_l \) with representation matrices

\[
E_p(C_N^j) = \begin{pmatrix} \cos j \varphi & -\sin j \varphi \\ \sin j \varphi & \cos j \varphi \end{pmatrix}, \quad E_p(U_j) = \begin{pmatrix} \cos j \varphi & \sin j \varphi \\ -\sin j \varphi & \cos j \varphi \end{pmatrix}.
\]

Taking all these relations into account one obtains

\[
\begin{align*}
B_{11}^{C1Ck} E_p(C_N^j) &= B_{22}^{C1Ck} E_p(C_N^j) = B_{11}^{C1Ck} E_p(U_j) = -B_{22}^{C1Ck} E_p(U_j) = \cos j \varphi, \\
B_{12}^{C1Ck} E_p(C_N^j) &= -B_{21}^{C1Ck} E_p(C_N^j) = B_{12}^{C1Ck} E_p(U_j) = B_{21}^{C1Ck} E_p(U_j) = \sin j \varphi.
\end{align*}
\]

When the subgroup \( V \) is dihedral than the repetition index can be omitted, but two types of dihedral subgroups have to be considered. It leads to the following formulas:

\[
\begin{align*}
B_{r=1}^{D1Dk} E_p(C_N^j) &= B_{r=1}^{D1Dk} E_p(U_j) = \cos j \varphi, \\
B_{r=2}^{D1Dk} E_p(U_j) &= -B_{r=2}^{D1Dk} E_p(C_N^j) = \sin j \varphi, \\
B_{r=1}^{D1Dk} E_p(C_N^j) &= B_{r=1}^{D1Dk} E_p(U_j) = \cos(j - 1/2) \varphi, \\
B_{r=2}^{D1Dk} E_p(U_j) &= -B_{r=2}^{D1Dk} E_p(C_N^j) = \sin(j - 1/2) \varphi.
\end{align*}
\]

The case \( U = D_l, V = C_k \) is a bit easier to discuss, since the left cosets \( g_j D_l \) are represented by the elements \( C_N^j \) only,

\[
\begin{align*}
B_{s=1}^{D1Ck} E_p(C_N^j) &= \cos j \varphi, \\
B_{s=2}^{D1Ck} E_p(g_j) &= \sin j \varphi, \\
B_{s=1}^{D1Ck} E_p(C_N^j) &= \cos(j + 1/2) \varphi, \\
B_{s=2}^{D1Ck} E_p(g_j) &= \sin(j + 1/2) \varphi.
\end{align*}
\]

In the last four cases both subgroups are dihedral, so \( g_j = C_N^j \) and different types of subgroups are considered. The final results are as follows:

\[
\begin{align*}
B_{r=1}^{D1Dk} E_p(C_N^j) &= \cos j \varphi, \\
B_{r=2}^{D1Dk} E_p(C_N^j) &= \cos(j + 1/2) \varphi, \\
B_{r=1}^{D1Dk} E_p(C_N^j) &= \cos(j - 1/2) \varphi, \\
B_{r=2}^{D1Dk} E_p(C_N^j) &= \cos j \varphi.
\end{align*}
\]

The equation presented together with Eqs. (15–22) enable us to determine matrix elements for any operator commuting with \( P(g) \).
3 Example

Let us consider a ring of six spins $s = 1$ with the symmetry group $D_6$ and the antiferromagnetic interactions of the nearest-neighbors ($J = -1$)

$$\mathcal{H} = \sum_{j=1}^{6} s_j \cdot s_{j+1}, \quad 6 + j \equiv j;$$

The dimension of the space of states is $(2s + 1)^N = 729$, so it is not so large, but it is sufficient to illustrate application of the method presented in this paper.

Since in this case the magnetization is a good quantum number, then at first we consider ordered and non-ordered partitions of $N = 6$ into no more than $2s + 1 = 3$ parts. There are seven ordered partitions: $[600], [510], [420], [411], [330], [321], \text{and } [222]$. They lead to 28 non-ordered partitions, which were presented in the previous paper [3] in Table 1. On the other hand, some simple combinatorial considerations yield the dimensions of subspaces with given magnetization $M \geq 0$. The results obtained are collected in Table 3. Due to the time-reversal symmetry it is enough to consider the states with $M \geq 0$.

The non-ordered partitions determine orbits of the symmetric group $\Sigma_6$. The action of $D_6 \subset \Sigma_6$ decomposes them into orbits labeled by subgroups $U \subset D_6$ (see Sec. 2.2 and Fig. 2). These decompositions depend only on the type of $[k]$, i.e. on the ordered partition $[\kappa]$, and are presented below (the number before a subgroup symbol $U$ denotes the multiplicity of orbits of the same type $\tilde{U}$):

$$[6] : D_6; \quad [51] : D_1^0; \quad [42] : D_2, D_1^0, D_1^1; \quad [33] : D_3^0, D_1^0, C_1;$$

$$[411] : D_1^0, 2C_1; \quad [321] : 2D_1^0, 4C_1; \quad [222] : C_2, 3D_1^0, 3D_1^1, 4C_1.$$ 

These results yield classification of orbits by the magnetization $M$ and the type $\tilde{U}$:

$M = 6 : D_6; \quad M = 5 : D_1^0; \quad M = 4 : D_2, 2D_1^0, D_1^1; \quad M = 3 : D_3^0, 2D_1^0, 3C_1; \quad M = 2 : D_2, 2D_1^0, 3C_1, 4C_1,
Table 4: Classification of states by the magnetization $M \geq 0$ and the irrep $\Gamma$

| $M$ | $A_1$ | $A_2$ | $B_1$ | $B_2$ | $E_1$ | $E_2$ | dim $L_M$ |
|-----|-------|-------|-------|-------|-------|-------|----------|
| 6   | 1     | 0     | 0     | 0     | 0     | 0     | 1        |
| 5   | 1     | 0     | 1     | 0     | 1     | 1     | 6        |
| 4   | 4     | 0     | 2     | 1     | 4     | 3     | 21       |
| 3   | 6     | 3     | 6     | 3     | 8     | 8     | 50       |
| 2   | 12    | 4     | 8     | 6     | 16    | 14    | 90       |
| 1   | 13    | 8     | 13    | 8     | 21    | 21    | 126      |
| 0   | 18    | 8     | 13    | 10    | 22    | 24    | 141      |
|     | Total | 92    | 38    | 73    | 46    | 122   | 118      |

$M = 2 : 2D_2, 4D_1^0, 2D_1^1, 4C_1$; $M = 1 : 5D_1^0, 8C_1$; $M = 0 : D_6, D_3^0, C_2, 5D_1^0, 3D_1^1, 7C_1$.

Now, taking into account the decompositions presented in Table 2, we can write down the multiplicities $n(\Gamma, P \downarrow L_M)$ for each $M \geq 0$. The numbers presented in Table 4 give us the dimension of the eigenproblem $H|\psi\rangle = E|\psi\rangle$ restricted to the states with a given magnetization $M$ and the symmetry described by $\Gamma$. The largest dimension is reached for $M = 0$ and $\Gamma = E_2$. However, when we are interested in the ground state only, then $\Gamma = A_1$ and the largest eigenproblem has dimension $18 \approx 729/40$. We can decrease these numbers even more taking into the square of the total spin $S^2$. Since eigenvalues of this operator are $S(S+1)$ for $0 \leq S \leq 6$, then it is enough to find the corresponding eigenvectors and express the Hamiltonian matrix in this new basis. Table 4 provides us also with dimensions dim $L_M=\Gamma$ of subspaces with a given total spin $S$ and the maximum magnetization $M = S$ corresponding to an irrep $\Gamma$. It is enough to subtract adjoining rows of this table (except for the first one since dim $L_{M=S=N_s} = \text{dim } L_{M=N_s}$), because states with $M = S$ are these with a given $M$ except for those with $S = M + 1$, which are listed in the previous row. For example, the dimensions dim $L_{M=S,A_1}$ are 5, 1, 6, 2, 3, 0, and 1 for $S = 0, 1, \ldots, 6$, respectively. In the same way one obtains that the subspace of states with $M = S = 0$ has the dimension dim $L_{M=S=0} = 15$ and

$$P \downarrow L_{M=S=0} = 5A_1 \oplus 2B_2 \oplus E_1 \oplus 3E_2,$$

so the dimension of the Hamiltonian eigenproblem in this case is at most five. The overall maximum is reached for $M = S = 2$ and $\Gamma = E_1$ and equals eight, i.e. about one ninetieth of the original dimension dim $L = 729$.

Let us restrict the further considerations to the case $M = S = 0$ and $\Gamma = A_1$. There are 18 orbits grouped into four classes labeled by the non-ordered partitions [060], [141], [222], and [303]; their representatives are presented in Fig. 3. Using the symbols $|U[k]|\mu$, where $U$ is a stabilizer, [k] — a non-ordered partition, and $\mu$ — a configuration expressed.
Figure 3: Orbit representatives for $N = 6$, $s = 1$ and $M = 0$; full and empty circles denote $m_j = +1, -1$, respectively.

as a series $(m_1, \ldots, m_6)$ with $\pm$ standing for $\pm 1$, respectively, these representatives can be written as:

$$
|1\rangle = |D_6 [060] (0, 0, 0, 0, 0, 0)\rangle, \\
|2\rangle = |D_6 [141] (0, 0, 0, 0, 0, 0)\rangle, \\
|3\rangle = |C_1 [141] (+, -, 0, 0, 0, 0)\rangle, \\
|4\rangle = |C_1 [141] (0, 0, -, 0, 0, 0)\rangle, \\
|5\rangle = |C_2 [222] (+, 0, -, +, 0, -)\rangle, \\
|6\rangle = |D_1 [222] (0, +, 0, - , - , +)\rangle, \\
|7\rangle = |D_1 [222] (+, 0, 0, +, 0, -)\rangle, \\
|8\rangle = |D_1 [222] (0, +, 0, - , - , +)\rangle, \\
|9\rangle = |D_1 [222] (+, +, 0, - , - , -)\rangle, \\
|10\rangle = |D_1 [222] (+, +, 0, +, 0, -)\rangle, \\
|11\rangle = |D_1 [222] (-, - , + , 0 , + , -)\rangle, \\
|12\rangle = |C_1 [222] (-, + , 0 , + , 0 , -)\rangle, \\
|13\rangle = |C_1 [222] (+, 0, +, 0, +, -)\rangle, \\
|14\rangle = |C_1 [222] (+, 0, +, 0, - , +)\rangle, \\
|15\rangle = |C_1 [222] (+, +, 0, 0, - , +)\rangle, \\
|16\rangle = |D_0 [303] (+, + , + , + , + , +)\rangle, \\
|17\rangle = |D_0 [303] (-, -, - , - , - , -)\rangle.
$$

Each orbit gives rise to only one state $|j; A_1\rangle \equiv |j'\rangle$, $j = 1, 2, \ldots, 18$, with symmetry $\Gamma = A_1$ constructed as a normalized sum of all $|D_6/[U|U\rangle$ states in a given orbit $O(U, [k], \mu) \equiv O_j$.

Since the Hamiltonian considered is isotropic, then we can use the total spin number $S$ to label eigenstates. The operator $S^2$ can be expressed as

$$
S^2 = \sum_{i=1}^{6} s_i^2 + 2 \sum_{i=1}^{5} \sum_{i'=i+1}^{6} s_i \cdot s_{i'} = 12 + 2\mathcal{H} + 2 \sum_{i=1}^{6} s_i \cdot s_{i+2} + 2 \sum_{i=1}^{3} s_i \cdot s_{i+3}.
$$

The diagonal parts of $\mathcal{H}$ and $S^2$ are given as

$$
\mathcal{H}_{\text{diag}} = \sum_{i=1}^{6} s_i^2 s_{i+1}^2,
\quad S_{\text{diag}}^2 = 12 + 2\mathcal{H}_{\text{diag}} + 2 \sum_{i=1}^{6} s_i^2 s_{i+2}^2 + 2 \sum_{i=1}^{3} s_i^2 s_{i+3}^2.
$$
In the first case (for $H_{\text{diag}}$) one obtains the following 18 eigenvalues: 0, 0, -1, 0, -2, -2, -2, -2, 2, -1, -1, 0, 0, -3, 1, -6, 2, and -2. The case of $S^2$ operator is even more simple, since the diagonal values depend only on the partition $[k]$ and one obtains four numbers: 12, 10 (orbits 2, 3, 4), 8 (orbits 5 through 15), and 6 (orbits 16, 17, 18).

To consider off-diagonal terms containing step operators $s_i^\pm$ we start with a graph of partitions:

```
[060] [141] [222] [303]
```

This graph leads a block structure of off-diagonal parts of the Hamiltonian and $S^2$ (symmetric) matrices:

\[
\begin{pmatrix}
0 & C & 0 & 0 \\
C^\dagger & A & D & 0 \\
0 & D^\dagger & B & E \\
0 & 0 & E^\dagger & 0
\end{pmatrix},
\]

where rows and columns are labeled by non-ordered partitions and $\dagger$ denotes the Hermitian conjugation. All these blocks may contain non-zero elements for $\Gamma = A_1$, because this representation appears in the decomposition of any transitive irreps. More detailed structure can be obtained if orbit stabilizers are taken into account (now rows and columns are labeled by pairs $(U, [k])$; borders of the blocks introduced above are denoted by lines):

\[
\begin{pmatrix}
0 & C_1 & C_2 & 0 & 0 \\
C_1^\dagger & A_1 & A_3 & D_1 & D_2 & D_3 & D_4 \\
C_2^\dagger & A_3 & A_2 & D_5 & D_6 & D_7 & D_8 \\
0 & D_1^\dagger & D_5^\dagger & B_1 & B_5 & B_6 & B_7 & E_1 & E_2 & E_3 \\
D_2^\dagger & D_6^\dagger & B_2 & B_5 & B_8 & B_9 & E_4 & E_5 & E_6 \\
D_3^\dagger & D_7^\dagger & B_3 & B_8 & B_{10} & E_7 & E_8 & E_9 \\
D_4^\dagger & D_8^\dagger & B_4 & B_{10} & E_{10} & E_{11} & E_{12} \\
0 & 0 & E_1^\dagger & E_2^\dagger & E_3^\dagger & E_7^\dagger & E_{10}^\dagger \\
0 & 0 & E_2^\dagger & E_5^\dagger & E_8^\dagger & E_{11}^\dagger \\
0 & 0 & E_3^\dagger & E_9^\dagger & E_{12}^\dagger & E_{12}^\dagger & E_{10}^\dagger & E_{11}^\dagger & E_{12}^\dagger & 0
\end{pmatrix}
\]

Depending on the representation considered some blocks have to contain only zeroes. For example, when $\Gamma = A_2$, then only blocks $A_2, B_1, B_4, B_7, D_5, D_8, E_3, E_{12}$ may contain non-zero entries. It follows from the fact that the irrep $A_2$ appears in the decomposition of a transitive representation $R^{\Sigma:U}$ if $U$ is a cyclic subgroup of $D_N$.

The classification of orbits with $M = 0$ by type $\tilde{U}$ yields that there are six different types of orbits, namely $D_6, D_3^0, C_2, D_1^0, D_1^1, C_1$, so there are 21 different double cosets to be considered. However, the matrix structure presented above excludes cosets $D_6gD_6, D_6gD_3, D_6gD_1$, and $D_3^0gD_3^0$.

Two notes are in place: (i) since we consider the case $\Gamma = A_1$, so all coefficients $B^{\Sigma\Gamma} = 1$; (ii) the off-diagonal terms contain products $s_i^+s_i^-$, which acting on kets
\[ |m_i m_{i'} \rangle \text{ gives zero or } 2|m_i + 1 m_{i'} - 1 \rangle, \text{ therefore terms } (s_i^+ s_{i'}^- + s_i^- s_{i'}^+)/2 \text{ are replaced by } \\
\sigma_i^+ \sigma_{i'}^- + \sigma_i^- \sigma_{i'}^+, \text{ where } \sigma_i^{+1} | \pm 1 \rangle = | \rangle \text{ and } \sigma_i^+ |m_i \rangle = |m_i \pm 1 \rangle, \text{ otherwise.} \]

Let us consider, as an example, the 16th column of an operator matrix. This column corresponds to the two-element orbit containing the Néel configurations \(|+, -, +, -\rangle\) and \(|-, +, -, +\rangle\) with a stabilizer \(D_3^0\) and labeled by the non-ordered partition \([302]\). Therefore, non-zero entries in this column, for operators constructed of bilinear terms, can appear only in the block \(E\), \(i.e.\) rows labeled by the partition \([222]\) (except for the diagonal terms \(\sum_{i,i'} s_i^+ s_{i'}^-\)). So, one has to consider four sets of double cosets \(D_3^0 \backslash D_6 / \langle U \rangle\) with \(U = C_2, D_3^0, D_4^1,\) and \(C_1\). In all cases \(k = 3\) and \(\lambda = 3\); in the first case \((U = C_2)\) \(l = 2, \lambda = 3, \text{ so } sd(k, l) = 6\) and \(\chi = 1\), whereas in the other cases we have \(l = 1, \lambda = 6, sd(k, l) = 3\) and \(\chi = 2\). Eqs. (16), (17), and (24) yield the following formulas (the repetition indices \(r, s\) may be omitted):

\[
\begin{align*}
 h_{C_{2\mu} D_6^{\nu}}(A_1) &= 2\sqrt{3} \ f(E); \\
 h_{C_{1\mu} D_6^{\nu}}(A_1) &= \sqrt{6} \left( f(E) + f(C_6) \right); \\
 h_{D_{1\mu} D_6^{\nu}}(A_1) &= 2 \sqrt{3} \ f(E); \\
 h_{D_{1\mu} D_6^{\nu}}(A_1) &= \sqrt{3} \left( f(E) + f(C_6) \right).
\end{align*}
\]

Therefore, one has to take into account the states \(|j\rangle\), for \(5 \leq j \leq 15\) and \(P(C_6)|j\rangle\) for \(j = 6, 7, 8, 12, 13, 14,\) and \(15\). Only two of them are obtained from \(|16\rangle\) under the action of bilinear terms \(\sigma_i^+ \sigma_{i'}^-\), namely

\[
P(C_6)|7\rangle = |+, 0, +, -, 0, -\rangle = \sigma_2^+ \sigma_5^- |+, -, +, -, +, -\rangle,
\]

and

\[
|14\rangle = |+, -, +, 0, 0, -\rangle = \sigma_1^+ \sigma_5^- |+, -, +, -, +, -\rangle.
\]

Hence, the non-zero off-diagonal terms in the sixteenth columns are

\[
\mathcal{H}_{14,16} = \sqrt{6}; \quad \mathbf{S}_{7,16}^2 = 2\sqrt{3}, \quad \mathbf{S}_{14,16}^2 = 2\sqrt{6}.
\]

All other elements of operator matrices can be obtained using the following formulas:

\[
\begin{align*}
 h_{C_{1\mu} D_6^{\nu}}(A_1) &= \sqrt{2} h_{D_{1\mu} D_6^{\nu}}(A_1) = 2\sqrt{3} \ f(E); \\
 h_{D_{1\mu} C_{2\nu}}(A_1) &= h_{D_{1\mu} C_{2\nu}}(A_1) = h_{D_{1\mu} D_{1\nu}}(A_1) = 2 \sum_{d=0}^2 f(C_6^d), \\
 h_{C_{1\mu} C_{2\nu}}(A_1) &= \sqrt{2} h_{C_{2\mu} C_{2\nu}}(A_1) = \sqrt{2} \sum_{d=0}^2 \left( f(C_6^d) + f(U_d) \right); \\
 h_{D_{1\mu} D_{1\nu}}(A_1) &= h_{D_{1\mu} D_{1\nu}}(A_1) = f(E) + f(C_6^3) + 2 \left( f(C_6^1) + f(C_6^2) \right); \\
 h_{C_{1\mu} D_{1\nu}}(A_1) &= h_{C_{1\mu} D_{1\nu}}(A_1) = \sqrt{2} \sum_{d=0}^5 f(C_6^d); \\
 h_{C_{1\mu} C_{1\nu}}(A_1) &= \sum_{d=0}^5 \left( f(C_6^d) + f(U_d) \right).
\end{align*}
\]
Table 5: The Hamiltonian (the upper triangle) and $S^2/2$ (the lower triangle) matrices for $N = 6$ spins $s = 1$ in the basis \{\ket{j'} \equiv \ket{j; A_1} | 1 \leq j \leq 18\} (the lines are borders of blocks $A$, $B$, $C$, $D$, and $E$).

\end{array}
\]

The matrices of the Hamiltonian $\mathcal{H}$ and the square of total spin $S^2$ are presented in Table 5.

The irrep $A_1$ has not been chosen merely due to the simplest form of the coefficients $B^{UV A_1}(g)$, but in order to illustrate the other way of determination of matrix elements in this case. Let an orbit $O_j$ consists of $n_j = |G|/|U_j|$ elements ($U_j$ is a stabilizer of the configuration $\ket{j} \equiv \ket{U_j[k] \mu}$). Hence, the fully symmetric state $\ket{j'} \equiv \ket{j; \Gamma_0}$ is given as

$$
\ket{j'} = \frac{1}{\sqrt{n_j}} \sum_{i=1}^{n_j} P(g_i) \ket{j},
$$

(43)

where $g_i$ are representatives of left cosets $g_i U_j \in G/U_j$. Since a stabilizer of each element in the orbit $O_j$ has $|U_j|$ elements than

$$
\ket{j'} = \frac{1}{|U_j| \sqrt{n_j}} \sum_{g \in G} P(g) \ket{j} \sum_{g \in G} P(g) \ket{j}.
$$

Let $\mathcal{H}'$ denote the off-diagonal part of a Hamiltonian $\mathcal{H}$, i.e. $\mathcal{H}' = \mathcal{H} - \mathcal{H}_{\text{diag}}$. The
symmetry operators $P(g)$ commute with a Hamiltonian $H'$, so

$$H'|j'\rangle = \frac{\sqrt{n_j}}{|G|} \sum_{g \in G} P(g)|H'|j\rangle .$$

To simplify the further considerations we limit ourselves to the cases $s = 1/2, 1$, when $s_i^+ s_i^- |m_i, \ldots, m_{i'}\rangle = |m_i + 1, m_{i'} - 1\rangle$ or $\sigma_i^+ \sigma_i^- |m_i, m_{i'} \ldots\rangle = |m_i + 1, m_{i'} - 1\rangle$, since in the case of larger spin numbers more detailed discussion is necessary. Under this assumption, each of off-diagonal terms of the bilinear Hamiltonian gives the empty state $|\rangle$ or one configuration without any coefficients. Let $n_{jk}$ denote a number of configurations obtained from $|j\rangle$ (by the action of $H'$) and belonging to the orbit $O_k$. Then $\sum_g P(g)|H'|j\rangle$ contains $|G|n_{jk}$ configurations from the orbit $O_k$. Since the state $|k'\rangle \equiv |k; A_i\rangle$ are constructed from all $n_k$ elements of the orbit $O_k$, then $|G|n_{jk}$ has to be divisible by $n_k$ and each element the orbit $O_k$ appears $|G|n_{jk}/n_k$ times in the considered sum $\sum_g P(g)|H'|j\rangle$. Therefore, one can construct $|G|n_{jk}/\sqrt{n_k}$ vectors $|k'\rangle$. As the result we obtain

$$\langle k'|H'|j\rangle = \frac{\sqrt{n_j}}{|G|} \frac{|G|n_{jk}}{\sqrt{n_k}} = n_{jk} \frac{n_j}{n_k} \frac{|U_k|}{|U_j|} .$$

In the example presented above $|j\rangle = |+, -, +, -, +, -\rangle$ and the off-diagonal terms of the Hamiltonian give us six configurations belonging to the orbit $O_{14}$ (with $n_{14} = 12$). The additional terms in $S^2$ operator lead to three configurations in the 6-element orbit $O_7$. Therefore,

$$H'_{14,16} = \frac{1}{2} S^2_{14,16} = 6 \sqrt{\frac{2}{12}} = \sqrt{6}; \quad \frac{1}{2} S^2_{7,16} = 3 \sqrt{\frac{2}{6}} = \sqrt{3} ,$$

what agrees with the previous results.

The further considerations go beyond the scope of this paper, since there are some numerical rather than combinatorial problems. However, we are very close to the solution of the eigenproblem and it is interesting to calculate the ground state energy. In the case of isotropic Hamiltonians, when $S$ is a good quantum number, we determine an orthonormal basis for each space $L_{M=S,A_1}$ solving the eigenproblem $S^2|\phi\rangle = S(S+1)|\phi\rangle$ for $S = 0, 1, 2, 3, 4, 6$ ($S = 5$ may be omitted since there are no states with $M = S = 5$ and $\Gamma = A_1$). It can be done, for example, using such packages as MATHEMATICA® or numerical libraries for calculations with an arbitrary precision as GMP [3]. Then, we transform the Hamiltonian to this new basis, what leads to a quasi-diagonal matrix consisting of blocks with dimensions 5, 1, 6, 2, 3, 1 for $S = 0, 1, 2, 3, 4, 6$, respectively. It is easy to solve the eigenproblems for such small blocks and, for example, in the case $S = 0$ we obtain five eigenvalues: $-8.6174, -4.7979, -3.3302, -0.3391, 3.0846$, where the first one corresponds to the ground state with energy per spin $-1.43624$. In the case of
such small eigenproblems one can also determine eigenstates\(^2\) and, therefore, it is possible to calculate spin correlations in the ground state.

4 Final remarks

In this paper we have studied properties of the dihedral groups \(D_N\) to obtain analytical formulas for number of double cosets and their elements. These results are necessary to exploit in full symmetry properties of a given spin operator and to obtain its matrix elements in the symmetry adapted basis. The groups considered are important in investigation of magnetic macromolecules forming rings or other structures with isomorphic symmetry group (e.g. crown-like structures). In a sense this paper, together with the preceding one \(\[6\]\), continues works done for the cyclic groups by T. Lulek and one of the authors (WF) \(\[11\]\). In those articles the arithmetic structure of a number of nodes \(N\) was mostly taken into account and some combinatorial object were considered. The present series of papers is mainly devoted to combinatorial and group-theoretical objects and the most important result is the formula for matrix elements expressed as the sum over representatives of double cosets. In the case of dihedral groups the approach proposed has two advantages: (i) all formulas can be obtained in analytical form and they can be used in computer programmes; (ii) in one dimension a loop over double coset representatives is, in general, shorter than a loop over all off-diagonal elements of bilinear Heisenberg Hamiltonian, what has been discussed in the previous paper \(\[6\]\); moreover, it is easy to modify Hamiltonian introducing, for example, interactions with the next nearest neighbors or alternating exchange integrals.

It should be underlined, however, that the final diagonalization of a given Hamiltonian is (almost) always done numerically, with all round-off errors caused by the float-point representation of numbers. Secondly, the method proposed only slightly increase the size of system which can be investigated. The so-called ‘combinatorial explosion’ leads to very large eigenproblems for quite small systems: e.g. a system consisting of twelve spins \(s = 2\) yields more than 240 millions Ising configurations, so there are about ten millions orbits of the dihedral group \(D_{12}\); more than 800 thousands orbits correspond to \(M = 0\), so this is the approximate of \(S^2\) eigenproblem dimension. On the other hand, not so much smaller system with \(N = 8\) leads to about 2,500 orbits with \(M = 0\), what can be investigated using modern computers. A number in the same range is obtained for \(N = 19\) and \(s = 1/2\),

\(^2\)Due to its form the eigenproblem for \(S^2\) can be solved exactly in many cases. This leads to an exact form of blocks in the Hamiltonian matrix. However, the Hamiltonian eigenproblem, except for some special cases, has to be solved numerically with the precision depending on software and hardware used. Therefore, all numbers obtained give only approximate values of energies, correlations, vector coefficients etc.
but we hope to determine the ground state energy for the Heisenberg antiferromagnetic ring with $N = 24$ nodes, where a system of about 50 thousand linear equations has to be solved. However, if one would like to determine the thermodynamic properties then all states have to be taken account, among others these with the symmetry $\Gamma = E_p$, which are double-fold degenerated, so the dimension of $S^2$ eigenproblem is approximately two times larger than that for one-dimensional irreps.
