DISCRETE FRAMES FOR $L^2(\mathbb{R}^{2^n})$ ARISING FROM TILING SYSTEMS ON $GL_n(\mathbb{R})$

MAHYA GHANDEHARI AND KRIS HOLLINGSWORTH

Abstract. A discrete frame for $L^2(\mathbb{R}^d)$ is a countable sequence $\{e_j\}_{j \in J}$ in $L^2(\mathbb{R}^d)$ together with real constants $0 < A \leq B < \infty$ such that

$$A \|f\|_2^2 \leq \sum_{j \in J} |\langle f, e_j \rangle|^2 \leq B \|f\|_2^2,$$

for all $f \in L^2(\mathbb{R}^d)$. We present a method of sampling continuous frames, which arise from square-integrable representations of affine-type groups, to create discrete frames for high-dimensional signals. Our method relies on partitioning the ambient space by using a suitable “tiling system”. We provide all relevant details for constructions in the case of $M_n(\mathbb{R}) \rtimes GL_n(\mathbb{R})$, although the methods discussed here are general and could be adapted to many other settings. Finally, we prove significantly improved frame bounds over the previously known construction for the case of $n = 2$.

Keywords: Continuous Wavelet Transform, Square-Integrable Representation, Discrete Frame, Quasiregular Representation, Tiling System

1. Introduction

An important and challenging problem in frame theory is to construct frames which allow suitable representations for signals from various classes of interest. Frames generalize the notion of a basis for a Hilbert space—that is, frames permit redundant encoding of signals while still yielding stable reconstruction methods. Since they are explicitly constructed for specific classes of data at hand, generalizing the known frame constructions to other datasets is a very difficult task. For instance, the classical Fourier basis efficiently represents a harmonic signal in terms of its frequencies (global property of the signal); however, it represents localized signals (i.e. functions with compact support) quite inefficiently. A fruitful strategy for creating novel frames is to employ the theory of wavelets, which emerged over three decades ago. Classical 1-dimensional wavelets may be formed in such a way as to have rapid decay in both spatial and frequency domains, and thus may be used to construct frames for the space of localized 1-dimensional signals. Unfortunately, the classical wavelet transform is ineffective when dealing with 2-dimensional signals. In fact, this transform is isotropic and cannot provide information about the geometry of nonisotropic signals in two dimensions. However, there are instances of 2-dimensional wavelet-type transforms, such as curvelet transforms (introduced in 2000, see [1, 2, 3, 4, 5]) and shearlet transforms (introduced in 2006, see [6, 7, 8]), which have proven extremely successful in the analysis and denoising of signals presenting anisotropic features.

As the dimension of the signal space grows, developing suitable and efficient frames becomes highly nontrivial. The easiest method for handling multi-dimensional cases would be to simply use the tensor product of 1-dimensional solutions. However, this approach does not capture many of the geometric features of high-dimensional signals. The methods in this article are based on a representation theoretic point of view, developed in [9], where a general framework for the construction of higher dimensional
continuous wavelet transforms was investigated. Essentially, if a locally compact group \( H \) acts on \( \mathbb{R}^n \) in such a manner that \( H \) acts freely and transitively on an open subset \( O \) in \( \mathbb{R}^n \), then an associated continuous wavelet transform theory can be developed as described in Section 2. The 2-dimensional continuous shearlet transform can be viewed in this manner (see [10] and [11]). Various methods, such as careful geometric techniques, can then be used to discretize continuous wavelet transforms, or continuous frames resulting from them, in order to produce discrete frames.

Discrete Frames. Discrete frames were initially introduced in 1952 by Duffin and Schaeffer [12], but it was not until the mid 1980s into the early 1990s that their use became of increased interest due to the work of Daubechies and her collaborators [13, 14]. Formally, a discrete frame for a separable Hilbert space \( H \) is a set of vectors \( \{ \phi_x \}_{x \in X} \) with \( X \) a countable index set such that for every vector \( f \in H \),

\[
A\|f\|_H^2 \leq \sum_{x \in X} |\langle f, \phi_x \rangle_H|^2 \leq B\|f\|_H^2,
\]

for some positive real numbers \( A \) and \( B \). If these inequalities are satisfied, the vectors form a stable, possibly redundant system which still allows for reconstruction from the frame coefficients \( \{ \langle f, \phi_x \rangle \}_{x \in X} \). Except for the special case of tight frames (when \( A = B \)), reconstruction requires iterative schemes for which the convergence rate is highly sensitive to the frame condition number, defined as the ratio \( \frac{B}{A} \); consequently, one goal in designing frames for real applications is to minimize this ratio. For a detailed introduction to frame theory, see [15].

Continuous Frames. A continuous frame for a separable Hilbert space \( H \) is a collection of vectors \( \{ \phi_x \}_{x \in X} \) with \( X \) a locally compact Hausdorff space equipped with a positive Radon measure \( \mu \) satisfying

\[
A\|f\|_H^2 \leq \int_X |\langle f, \phi_x \rangle_H|^2 d\mu(x) \leq B\|f\|_H^2 \quad \forall f \in H,
\]

for some positive real numbers \( A \) and \( B \). Notice that when \( \mu \) is the counting measure on a countable space \( X \), this agrees with the previous definition of a discrete frame.

The term continuous frame appears to be attributable to Ali, Antoine, and Gazeau in [16], although the concept did not originate with them. Continuous frames for \( L^2(\mathbb{R}^n) \) were known to Calderón in the 1960s (see [17])—as such, some authors refer to the following as the Calderón reproducing formula (for example, [18]). Essentially, when \( \{ \phi_x \}_{x \in X} \) is a continuous frame, there exist vectors \( \{ \tilde{\phi}_x \}_{x \in X} \), called the dual frame, such that

\[
f = \int_X \langle f, \phi_x \rangle \tilde{\phi}_x d\mu(x), \quad \forall f \in H
\]

where the integral is interpreted in the weak sense. A thorough introduction for continuous reproducing formulas can be found in section 2 of [19].

A wavelet frame is one in which the frame vectors are all formed from translations and dilations (or translations and modulations in the case of Gabor frames) of a single mother or analyzing wavelet. Generalized versions of continuous wavelet transforms and frames, defined in Section 2, have been investigated extensively in the past couple of decades. In the present work, we restrict ourselves to constructions on Hilbert spaces, but information on continuous frames in certain Banach spaces can be found in [19]. For examples of wavelet transforms based on the theory of square-integrable representations, see [6, 20, 21, 22, 23, 24], and for the general theory governing their construction and behavior see [25, 26, 27, 28, 29, 30]. Continuous wavelet transforms arising from square-integrable
representations and their discretizations have also been investigated in the study of quantum mechanics
as special cases of coherent states, see for example chapter 9 of [31] and references therein.

Discretization. In 2016, Freeman and Speegle proved that every bounded continuous frame may be
sampled to obtain a discrete frame [32]. Their proof, however, is not constructive in nature, and
does not result in an efficient algorithm for discretizing continuous frames in general. Building on
this work, Führ and Oussa, [33], found large classes of Lie groups $G$ for which $L^2(G)$ admits discrete
frames of translates. In addition, several necessary and some sufficient conditions for existence of such
discrete frames are exhibited in [33]. Examples of previous approaches for discretizing continuous
wavelet transforms to construct discrete frames may be found in [34, 35].

In this paper, we restrict our attention to $L^2(\mathbb{R}^n)$. In [36], the authors prove $L^2(\mathbb{R}^n)$ does not admit
discrete frames of pure translates, in the sense that no collection $\bigcup_{a \in \Gamma} \{g_k(x-a)\}_{a \in \Gamma}$ can form a frame
for $L^2(\mathbb{R}^n)$, which demonstrates the necessity of more complex methods, such as the one we explore
in the current work.

Contents. In the present article, we seek to improve the results of [37], where the theory of square-
integrable representations was combined with the geometry of the Euclidean space to construct discrete
frames for $L^2(\mathbb{R}^4)$. As in [37], we follow the general method developed in [9] to construct a tight
continuous frame using representation theory of the group $\text{M}_n(\mathbb{R}) \rtimes \text{GL}_n(\mathbb{R})$. We then obtain a
discrete frame through careful geometric techniques for discretizing the reproducing formula. As a
result, we improve the construction in [37] significantly by reducing the frame condition number from
about 1782 to 54. More importantly, the previous construction was only provided for $L^2(\mathbb{R}^4)$ which
we generalize to $L^2(\mathbb{R}^{n^2})$ for any $n \in \mathbb{N}$. Note that square-integrable representations provide us with
the only reasonable framework to produce discrete frames, since the existence of a discrete frame in
this setting implies the square-integrability of the unitary representation generating the associated
continuous frame (see [38] for more details).

Finally, we compare our work with that of Heinlein and his collaborators in [39, 40]. The two
approaches rely on the same representation theoretic viewpoint. Indeed, we both discretize continu-
ous wavelet frames obtained from a square-integrable representation of the affine group; however,
we note three key differences. First, their strategy is to use integrated wavelets, which are averages
of a wavelet in the Fourier domain over any countable partition of the space (in our case $\mathbb{R}^{n^2}$) into
compact sets. With this method, they obtain tight frames, but this comes at the cost that the analysis
and reconstruction filters for $n$ resolution scales require $(n + 1)$ Fourier transforms. Consequently, the
computational cost of this method on higher-dimensional data would be extremely high, whereas our
method only requires one Fourier inversion of the analyzing wavelet. Second, we obtain and work with
a much more structured decomposition than their general partition (which they call detail decompo-
sition). Our approach starts with a “tile” which under the action of a discrete, countable set covers the
space. The structure of our tiling system reduces the amount of information needed for implementa-
tion, as one only needs to know the “mother tile” and the form of the discrete set acting on it. Thus,
the challenge here is to obtain such suitable tiling systems, which we overcome by carefully investigat-
ing the geometry of the space. Last, integrated wavelets require a two-step discretization. That is,
they must discretize translations and dilations separately, and it is the intermediate discretization on
dilations alone which provides a tight frame. Our method performs the discretization simultaneously,
allowing for a one-step process.

Organization. This paper is organized as follows. In Section 2 we collate all necessary definitions,
notations, and background. In Section 3 we provide the general theory for constructing discrete
frames from the continuous wavelet transform by means of tiling systems. In Section 4 we provide a general construction for tiling of $GL_n(\mathbb{R})$ for any $n \in \mathbb{N}$. In Section 5 we compute the frame bounds for the tiling system and derive an upper bound on the frame condition number as a function of the dimension $n$. We conclude the section by providing explicit details of the concrete construction for the case when $n = 2$. In Section 7 we end with a brief discussion of the future work.

2. Notations and Definitions

Let $n \in \mathbb{N}$, and $M_n(\mathbb{R})$ denote the set of $n \times n$ real matrices. Equipped with matrix addition and the topology of $\mathbb{R}^{n^2}$, the set $M_n(\mathbb{R})$ can be viewed as a locally compact abelian group. Let $GL_n(\mathbb{R})$ denote the subset of $M_n(\mathbb{R})$ containing all $n \times n$ real matrices with nonzero determinant. It is well-known that $GL_n(\mathbb{R})$ is an open subset of $M_n(\mathbb{R})$, as the determinant is a continuous function (in fact a polynomial) in the matrix entries. So, $GL_n(\mathbb{R})$ turns into a locally compact group, when equipped with matrix multiplication and the induced topology of $\mathbb{R}^{n^2}$. Elements of $GL_n(\mathbb{R})$ and $M_n(\mathbb{R})$ can be combined to form affine transformations as defined below.

**Definition 2.1.** For $x \in M_n(\mathbb{R})$ and $h \in GL_n(\mathbb{R})$, let $[x, h]$ denote the affine transformation of $M_n(\mathbb{R})$ given by

$$[x, h]y = hy + x \quad \text{for } y \in M_n(\mathbb{R}).$$

Let $M_n(\mathbb{R}) \times GL_n(\mathbb{R}) = \{ [x, h] : x \in M_n(\mathbb{R}), h \in GL_n(\mathbb{R}) \}$ denote the collection of all affine transformations defined above. Composition of transformations can be seen as the following product operation.

$$[x_1, h_1][x_2, h_2] = [x_1 + h_1x_2, h_1h_2].$$

Then $G_n := M_n(\mathbb{R}) \times GL_n(\mathbb{R})$, together with product (1), forms a non-abelian locally compact group when given the product topology. Let $I_n$ denote the $n \times n$ identity matrix, and $0_n$ denote the $n \times n$ zero matrix. It is easy to check that $[0_n, I_n]$ is the identity of $G_n$, and $[x, h]^{-1} = [-h^{-1}x, h^{-1}]$ for $[x, h] \in G_n$.

**Haar Integration.** The most useful measure on $G_n$ is its (unique, up to scaling) left-invariant measure, called the left Haar measure, which we explicitly describe. In what follows, all the functions appearing in the integration formulas are integrable and defined on the appropriate domains. First, we equip $M_n(\mathbb{R})$ with Lebesgue measure under the identification with $\mathbb{R}^{n^2}$, and let $\int f(x) \, dx$ denote the Lebesgue integration. That is,

$$dx = dx_{11}dx_{12} \cdots dx_{1n}dx_{21} \cdots dx_{n1} \cdots dx_{nn} \quad \text{if } x = \begin{pmatrix} x_{11} & x_{12} & \cdots & x_{1n} \\ \vdots & \vdots & \ddots & \vdots \\ x_{n1} & x_{n2} & \cdots & x_{nn} \end{pmatrix}.$$  

For $GL_n(\mathbb{R})$, the left Haar integration is given by $\int g(h) \, dh$, where

$$dh = \frac{dh_{11}dh_{12} \cdots dh_{1n}dh_{21} \cdots dh_{n1} \cdots dh_{nn}}{|\det(h)|^n} \quad \text{if } h = \begin{pmatrix} h_{11} & h_{12} & \cdots & h_{1n} \\ \vdots & \vdots & \ddots & \vdots \\ h_{n1} & h_{n2} & \cdots & h_{nn} \end{pmatrix},$$
where \( h = [h_{ij}]_{i,j=1}^n \) is a generic element of \( \text{GL}_n(\mathbb{R}) \). It turns out that the left Haar measure on \( \text{GL}_n(\mathbb{R}) \) is also right invariant, i.e. \( \text{GL}_n(\mathbb{R}) \) is unimodular. So, for any \( h' \in \text{GL}_n(\mathbb{R}) \) and a compactly supported function \( g \),

\[
\int_{\text{GL}_n(\mathbb{R})} g(h'h) \, dh = \int_{\text{GL}_n(\mathbb{R})} g(hh') \, dh = \int_{\text{GL}_n(\mathbb{R})} g(h^{-1}) \, dh = \int_{\text{GL}_n(\mathbb{R})} g(h) \, dh.
\]

Now we can describe left Haar integration on \( G_n \). For a compactly supported function \( f : G_n \to \mathbb{C} \),

\[
(2) \quad \int_{G_n} f([x, h]) \, d[x, h] = \int_{\text{GL}_n(\mathbb{R})} \int_{\text{M}_n(\mathbb{R})} f([x, h]) \frac{dx \, dh}{|\text{det}(h)|^n}.
\]

It is a routine calculation to show that the integration defined in (2) is invariant under left translations.

This integration is not right invariant. However, we have the following formula for handling the case of right translation.

\[
\int_{G_n} f([x, h][y, k]) \, d[x, h] = |\text{det}(k)|^n \int_{G_n} f([x, h]) \, d[x, h],
\]

for every \([y, k] \in G_n\). See [41] or [42] for the properties of Haar measure and the Haar integral in general.

Transferring to Fourier Domain. It turns out that the existence of a continuous wavelet transform depends crucially on the geometric features of the underlying group, and in particular the geometry of the action of \( \text{GL}_n(\mathbb{R}) \) on the Pontryagin dual of \( \text{M}_n(\mathbb{R}) \). To make notation more clear, \( \text{M}_n(\mathbb{R}) \) is denoted by \( A \), when it is identified with \( \mathbb{R}^{n^2} \) as an abelian group. Let \( \hat{A} \) denote the dual (i.e. the group of characters) of \( \text{M}_n(\mathbb{R}) \) under this identification. For the purpose of Fourier analysis on \( \mathbb{R}^{n^2} \), identified with \( \hat{A} \), we choose the following way to pair \( A \) with \( \hat{A} \). For \( b = [b_{ij}]_{i,j=1}^n \in A \), define \( \chi_b \in \hat{A} \) by

\[
(3) \quad \chi_b(x) = e^{2\pi i \text{tr}(bx)}, \quad x \in A.
\]

We have, \( \hat{A} = \{\chi_b : b \in A\} \). Thus, \( \hat{A} \) can also be identified with \( \mathbb{R}^{n^2} \), and Haar integration on \( \hat{A} \) is simply the Lebesgue integral, i.e.

\[
\int_{\hat{A}} g(x) \, d\chi = \int_{\mathbb{R}^{n^2}} g(\chi_b) \, db = \int_{\mathbb{R}} g(\chi(b_{11}, \ldots, b_{nn})) \, db_{11} \cdots db_{nn}.
\]

For \( f \in L^1(A) \), the Fourier transform \( \hat{f} : \hat{A} \to \mathbb{C} \) is given by \( \hat{f}(\chi) = \int_A f(x)\overline{\chi(x)} \, dx \), for all \( \chi \in \hat{A} \). If \( f \in L^1(A) \cap L^2(A) \), then \( \hat{f} \in L^2(\hat{A}) \) and \( \|\hat{f}\|_2 = \|f\|_2 \). So, the Fourier transform extends to a unitary map \( \mathcal{P} : L^2(A) \to L^2(\hat{A}) \), the Plancherel transform, such that \( \mathcal{P} f = \hat{f} \), for all \( f \in L^1(A) \cap L^2(A) \).

The group \( \text{GL}_n(\mathbb{R}) \) acts on \( A \) by matrix multiplication. This action determines an action of \( \text{GL}_n(\mathbb{R}) \) on the dual space \( \hat{A} \) by \( h \cdot \chi_b = \chi_{b^{-1}h} \), for \( b \in A \) and \( h \in \text{GL}_n(\mathbb{R}) \). This action scales Lebesgue measure, so that, for any integrable function \( \xi \) on \( \hat{A} \),

\[
(4) \quad \int_{\hat{A}} \xi(\chi) \, d\chi = |\text{det}(h)|^{-n} \int_{\hat{A}} \xi(h \cdot \chi) \, d\chi.
\]
A Square-Integrable Irreducible Representation. We now give two equivalent forms of the quasi-regular representation of $G_n$, which is the irreducible representation that has been used in [37] to construct continuous wavelet transforms. Let $\mathcal{H}$ be a Hilbert space, and $\mathcal{U}(\mathcal{H})$ denote the group of unitary operators on $\mathcal{H}$. A **continuous unitary representation** of a locally compact group $G$ on $\mathcal{H}$ is a group homomorphism $\pi : G \to \mathcal{U}(\mathcal{H})$ which is WOT-continuous, i.e. for every vectors $\xi$ and $\eta$ in $\mathcal{H}$, the function

$$\pi_{\xi,\eta} : G \to \mathbb{C}, \quad g \mapsto \langle \pi(g)\xi, \eta \rangle$$

is continuous. Functions of the form $\pi_{\xi,\eta}$, for vectors $\xi$ and $\eta$ in $\mathcal{H}$, are called the **coefficient functions** of $G$ associated with the representation $\pi$. If $\sigma_1$ and $\sigma_2$ are two representations of $G$ on $\mathcal{H}_1$ and $\mathcal{H}_2$ respectively, we say $\sigma_1$ is (unitarily) equivalent to $\sigma_2$ if there exists a unitary transformation $U : \mathcal{H}_1 \to \mathcal{H}_2$ such that

$$U\sigma_1(x) = \sigma_2(x)U, \text{ for all } x \in G.$$ 

A representation $\pi$ is called irreducible if $\{0\}$ and $\mathcal{H}$ are the only $\pi$-invariant closed subspaces of $\mathcal{H}$. Let $\hat{\mathcal{H}}$ denote the space of equivalence classes of irreducible representations of $G$. An introduction to the representation theory of locally compact groups can be found in [42].

An irreducible representation $\pi : G \to \mathcal{U}(\mathcal{H})$ is called **square-integrable** if there exist nonzero $\xi, \eta \in \mathcal{H}$ such that $\pi_{\xi,\eta} \in L^2(G)$, where $L^2(G)$ is the collection of all square-integrable complex-valued functions on $G$. With $\xi \in \mathcal{H} \setminus \{0\}$ fixed, if there exists one nonzero $\eta' \in \mathcal{H}$ with $\pi_{\xi,\eta'} \in L^2(G)$, then $\pi_{\xi,\eta} \in L^2(G)$ for any $\eta \in \mathcal{H}$. Such a vector $\xi$ is called **admissible** and the set of admissible vectors is dense in $\mathcal{H}$. For a comprehensive discussion of continuous wavelet transforms and their connection with square-integrable representations, see [30].

The results in the following proposition are proved in [37], so we skip the proof.

**Proposition 2.2.** Let $\mathcal{H}_1 = L^2(A)$ and $\mathcal{H}_2 = L^2(\hat{A})$. Then,

(i) $\rho$ is a unitary representation, where

$$\rho : G_n \to \mathcal{U}(\mathcal{H}_1), \quad \rho[x,h]g(y) = |\det(h)|^{-n/2}g(h^{-1}(y-x)),$$

for all $[x,h] \in G_n$ and $y \in A$.

(ii) $\pi$ is a unitary representation, where

$$\pi : G_n \to \mathcal{U}(\mathcal{H}_2), \quad \pi[x,h]\xi(\chi) = |\det(h)|^{n/2} \chi(x)\xi(h^{-1} \cdot \chi),$$

for all $[x,h] \in G_n$ and $\chi \in \hat{A}$.

(iii) The representations $\rho$ and $\pi$ are equivalent square-integrable irreducible representations of $G_n$. Namely, we have $\pi[x,h]\mathcal{P} = \mathcal{P}\rho[x,h]$, where $\mathcal{P}$ is the Plancherel transform.

Continuous Wavelet Transforms. We now use the square-integrable representations defined in the previous section to construct a continuous wavelet transform. Recall that by $A$ we denote $M_n(\mathbb{R})$, when it is identified with $\mathbb{R}^{n^2}$ as an abelian group. Let $\rho$ be the square-integrable representation defined earlier.

**Definition 2.3.** A function $\psi \in L^2(A)$ is called a **wavelet** if

$$\int_{\text{GL}_n(\mathbb{R})} \left| \hat{\psi}(\chi h) \right|^2 dh = 1. \tag{5}$$
A **continuous wavelet transform** (CWT) associated with a wavelet \( \psi \in L^2(A) \) is the linear transformation defined as

\[
V_\psi : L^2(M_n(\mathbb{R})) \to L^2(G_n), \quad V_\psi f[x,h] = \langle f, \rho[x,h] \psi \rangle,
\]

for \( f \in L^2(A), [x,h] \in G_n \).

It is known that a continuous wavelet transform \( V_\psi \) is an isometry of \( L^2(M_n(\mathbb{R})) \) into \( L^2(G_n) \), that is

\[
\langle f, g \rangle = \int_{G_n} \langle f, \rho[x,h] \psi \rangle \langle \rho[x,h] \psi, g \rangle \, d[x,h],
\]

for any \( f, g \in L^2(M_n(\mathbb{R})) \). This formula can be written in the following weak integral form:

\[
(6) \quad f = \int_{G_n} \langle f, \rho[x,h] \psi \rangle \rho[x,h] \psi \, d[x,h],
\]

for any \( f \in L^2(A) \). For notational convenience, we denote \( \rho[x,h] \psi \) by \( \psi_{x,h} \). See [30], for a detailed discussion about general CWTs, and [37] for the details of the above mentioned wavelet transform.

### 3. Constructing Frames using CWTs

In this section, we present a summary of the results from [9], explaining how CWTs may be used to construct discrete frames. The objective here is to construct frames of the form \( \{ \rho[x,h] \psi \} \) for \( [x,h] \in P \), where \( P \) is a discrete subset of \( G_n \), and \( \rho \) and \( \psi \) are as in Definition 2.3. The frame constructions in [9] heavily rely on the concept of a "tiling system" which we define here.

In [37], the first author and collaborators use the approach of [9] to construct a discrete frame for \( L^2(\mathbb{R}^4) \). More precisely, they obtain a suitable tiling system for \( \text{GL}_2(\mathbb{R}) \), which they use to discretize the continuous wavelet transform on \( \mathbb{R}^4 \). In this section, we extend their frame construction to general \( n \), obtaining discrete frames for \( L^2(\mathbb{R}^{n^2}) \). In addition, we obtain a much tighter gap between the frame bounds.

For what follows, we restrict ourselves to the groups which are being studied in this paper; although our methods can be carried out in more general settings.

**Definition 3.1.** Let \( P \) be a countable subset of \( \text{GL}_n(\mathbb{R}) \), and \( F \) be an open relatively compact subset of \( \text{GL}_n(\mathbb{R}) \). The pair \( (F,P) \) is called a **tiling system** for \( \text{GL}_n(\mathbb{R}) \) if the following two conditions are satisfied:

1. \( \lambda_{\text{GL}_n}(\overline{F} \cdot p \cap \overline{F} \cdot q) = 0 \) for every distinct pair \( p, q \in P \),
2. \( \lambda_{\text{GL}_n} \left( \text{GL}_n(\mathbb{R}) \setminus \bigcup_{p \in P} \overline{F} \cdot p \right) = 0 \),

where \( \lambda_{\text{GL}_n} \) denotes the left Haar measure of \( \text{GL}_n(\mathbb{R}) \), and \( \overline{F} \) denotes the closure of \( F \) in \( \text{GL}_n(\mathbb{R}) \). Note that conditions (i) and (ii) remain unchanged if one replaces \( \lambda_{\text{GL}_n} \) with \( \lambda_{M_n} \), the left Haar measure on \( \mathbb{R}^{n^2} \).

**Remark 3.2.** In the above definition, we think of a subset \( S \) of \( A = M_n(\mathbb{R}) \) as a subset \( \tilde{S} \) of \( \hat{A} \) in the following natural manner: \( \tilde{S} = \{ \chi_b : b \in S \} \). With this identification in mind, we have \( \overline{F} \cdot p = p^{-1} \cdot \overline{F} \).
Remark 3.3. Recall that we identify elements of $M_n(\mathbb{R})$ with vectors in $\mathbb{R}^{n^2}$. We do so via the map $\Phi$ given by

$$
\begin{pmatrix}
x_{11} & \ldots & x_{1n} \\
\vdots & \ddots & \vdots \\
x_{n1} & \ldots & x_{nn}
\end{pmatrix} \mapsto (x_{11}, \ldots, x_{1n}, \ldots, x_{n1}, \ldots, x_{nn}).
$$

(7)

The $n \times n$ matrix structure is only used when multiplication is involved. This identification allows us to transfer the notion of tiling to $\mathbb{R}^{n^2}$. Let $(F, P)$ be a tiling system for $\text{GL}_n(\mathbb{R})$. For each $p \in P$, let $L^2(\Phi(F \cdot p))$ denote the closed subspace of $L^2(\mathbb{R}^{n^2})$ consisting of functions that are zero almost everywhere on $\mathbb{R}^{n^2} \setminus \Phi(F \cdot p)$. Noting that $\text{GL}_n(\mathbb{R})$ is a co-null subset of $M_n(\mathbb{R})$ (and thus $\mathbb{R}^{n^2}$), we have that

$$L^2(\mathbb{R}^{n^2}) = \bigoplus_{p \in P} L^2(\Phi(F \cdot p)).$$

With this in mind, we can think of $(F, P)$ as a tiling system for $M_n(\mathbb{R})$, or equivalently for $\mathbb{R}^{n^2}$, as well.

We now give a brief review of the method introduced in [9] for constructing a frame from a tiling system. We first introduce some notations, which will be useful for the next theorem.

Notation 3.4. Let $(F, P)$ be a tiling system, and $R$ be a hypercube in $M_n(\mathbb{R})$ whose interior contains $\overline{F}$, i.e. $R$ is defined by real numbers $a_{ij} < b_{ij}$, $1 \leq i, j \leq n$ as follows.

$$R = \{[x_{ij}] \in M_n(\mathbb{R}) : a_{ij} \leq x_{ij} \leq b_{ij} \text{ for } i, j = 1, \ldots, n\}.$$ 

Let $|R| = \prod_{i,j=1}^{n}(b_{ij} - a_{ij})$ be the volume of the cube, and $J = \left\{ \left[\begin{smallmatrix} m_{ij} \\ \pi j/n - a_{ij} \end{smallmatrix}\right] : m_{ij} \in \mathbb{Z} \right\}.$

Every $\gamma \in J$ defines a character on the hypercube $R \subseteq M_n(\mathbb{R})$ as follows.

$$e_{\gamma}(y) = \frac{1}{\sqrt{|R|}} \mathbf{1}_R(y) \exp(2\pi i \text{tr}(\gamma y)),$$

for $y \in R$,

where $\mathbf{1}_R$ is the characteristic function of $R$. Then $\{e_{\gamma} : \gamma \in J\}$ is an orthonormal basis for $L^2(R)$.

We now prove a slightly different version of Theorem 3 of [9]. Even though our proof is similar to theirs, we manage to obtain a much tighter frame condition number due to our new definition for the constant $M$. In the following section, we will show that the conditions in our theorem can be met for $G_n = M_n(\mathbb{R}) \times \text{GL}_n(\mathbb{R})$ for any $n \in \mathbb{N}$.

Notation 3.5. Let $(F, P)$ be a tiling system for $\text{GL}_n(\mathbb{R})$, and $R$ be a hypercube containing $\overline{F}$. Let $F_o$ be an open set satisfying $F \subseteq F_o \subseteq R$. For $p \in P$, define $I_{F_o}(p) := \left\{ k \in P : F \cdot p \cap F_o \cdot k \neq \emptyset \right\}$. Let $M := \sup_{p \in P} |I_{F_o}(p)|$. Observe that $M$ is finite according to Lemma 4 of [9].

Theorem 3.6. Let $(F, P)$ be a tiling system for $\text{GL}_n(\mathbb{R})$, with $R$ and $F_o$ as in Notation 3.5. Let $g \in L^2(M_n(\mathbb{R}))$ be such that $1_{\overline{F}} \leq \hat{g} \leq 1_{F_o}$. Then $\{\rho[\lambda, p]^{-1}g : (\lambda, p) \in J \times P\}$ is a discrete frame in $L^2(M_n(\mathbb{R}))$, where $J$ is defined in Notation 3.4. Moreover, the lower and upper frame bounds are given by

$$|R| \|f\|_2^2 \leq \sum_{k \in P} \sum_{\gamma \in J} |\langle f, \rho[\gamma, k]^{-1}g \rangle| L^2(M_n(\mathbb{R})) |^2 \leq M|R| \|f\|_2^2,$$

with $M$ as in Notation 3.5.
This is known as Iwasawa decomposition. Moreover, the Haar measure of $E$ can be found in Lie theory literature.

**Proof.** For an arbitrary $f \in L^2(M_n(\mathbb{R}))$, we have

$$\sum_{k \in P} \sum_{\gamma \in J} |(f, \rho[\gamma, k]^{-1} g)_{L^2(M_n(\mathbb{R}))}|^2 = |R| \int_{M_n(\mathbb{R})} |\hat{f}(\chi_b)|^2 \left( \sum_{k \in P} |\hat{g}(\chi_{bk^{-1}})|^2 \right) db,$$

where the details follow as in [9], and so we omit them here. Note that for almost every $b \in M_n(\mathbb{R})$, there exists an element $k \in P$ for which $b \in F \cdot k$. This, together with the fact that $\hat{g} \geq 1_F$, implies that $\sum_{k \in P} |\hat{g}(\chi_{bk^{-1}})|^2 \geq 1$ for almost every $b \in M_n(\mathbb{R})$. Thus, $|R|$ is a lower bound for the frame. To obtain the upper bound, we note that $\hat{g} \leq 1$. Moreover, for almost every $b \in M_n(\mathbb{R})$, there are at most $M$ values of $k \in P$ for which $|\hat{g}(\chi_{bk^{-1}})| > 0$, as $\hat{g} \leq 1_F$. This finishes the proof. \hfill \Box

4. Tiling System for $GL_n(\mathbb{R})$

In this section, we generalize the construction of a tiling system for $GL_2(\mathbb{R})$ given in [37] to a tiling system for $GL_n(\mathbb{R})$. We then show this construction meets the conditions of Theorem 3.6. We compute the corresponding frame bounds in Section 5.

The definition of our tiling system in this section and the computations thereafter are inspired by the Iwasawa decomposition for $GL_n(\mathbb{R})$. For matrices, this decomposition is equivalent to the well-known Gram decomposition of a matrix; with the upper triangular part further decomposed into a diagonal matrix with positive entries and a unit upper triangular matrix. Finally, we factor out the determinant to use as a parameter in our tiling system. While this realization works for matrix groups, the Iwasawa decomposition is much more general, and could be applied to other semisimple Lie groups. This decomposition can be viewed as a change of variables when computing the Haar measure, for which we provide the relevant formulas here as well.

**Theorem 4.1 ([43, Proposition 2.3]).** Each $a \in GL_n(\mathbb{R})$ can be uniquely decomposed as $a = skwy$. Here, $k \in O_n$, $s \in \mathbb{R}^+$, $w \in D_n$, and $y \in T_n$, where $O_n$ is the orthogonal group in dimension $n$, $D_n$ is the group of diagonal matrices with positive diagonal entries and determinant 1, and $T_n$ is the group of unit upper triangular matrices. That is

$$GL_n(\mathbb{R}) = \left\{ \begin{pmatrix} w_1 & & & \\ & \ddots & & \\ & & w_{n-1} & \\ sk & & & \prod_{i=1}^{n-1} w_i^{-1} \end{pmatrix} \begin{pmatrix} 1 & y_{1,2} & \cdots & y_{1,n} \\ \cdots & \ddots & \cdots & \vdots \\ \cdots & \cdots & 1 & y_{n-1,n} \\ 1 & & & 1 \end{pmatrix} \right\} \left\{ s, w_i \in \mathbb{R}^+ \mid \begin{array}{c} y_{i,j} \in \mathbb{R} \\ k \in O_n \end{array} \right\}.$$

This is known as Iwasawa decomposition. Moreover, the Haar measure of $E \subseteq GL_n(\mathbb{R})$ can be computed in terms of the Euclidean coordinates in this decomposition as

$$\lambda_{GL_n(\mathbb{R})}(E) = \int_{\mathbb{R}^+ \times O_n \times D_n \times T_n} \mathbb{1}_E(skwy) s^{-1} \prod_{i=1}^{n-1} w_i^{2(n-i)-1} \, dk \, ds \prod_{i=1}^{n-1} dw_i \prod_{i<j} dy_{i,j},$$

where $dk$ is the normalized Haar measure on $O_n$, and $ds, dw_i, dy_{i,j}$ are Lebesgue measure on $\mathbb{R}$.

**Proof.** We include a short proof to be self-contained, even though proofs for similar decompositions can be found in Lie theory literature.

In this proof, we denote the Haar measure of a group $G$ by $\mu_G$. First note that $\det : GL_n(\mathbb{R}) \to \mathbb{R}^*$ is a group homomorphism, where $\mathbb{R}^*$ is the multiplicative group of nonzero real numbers. Clearly, $H := \det^{-1}(\{1, -1\})$ is a closed normal subgroup of $GL_n(\mathbb{R})$, and $\mathbb{R}^+$ is isomorphic with $GL_n(\mathbb{R})/H$. 
So by Theorem 2.51 of [42], the Haar measure of $\text{GL}_n(\mathbb{R})$ can be decomposed as $d\mu_{\text{GL}_n}(sx) = d\mu_{\mathbb{R}^+}(s) d\mu_H(x)$. Next, consider the Iwasawa decomposition $\text{SL}_n(\mathbb{R}) = \text{SO}_n \text{D}_n \text{T}_n$, and note that by taking inverse and allowing matrices with determinant of -1, we can write $H = \text{T}_n \text{D}_n \text{O}_n$. Since $\text{O}_n$ and $H$ are unimodular groups, we can apply Theorem 2.51 of [42] again, to get the decomposition $d\mu_H(yw) = d\mu_{\text{O}_n}(k) d\mu_{\text{T}_n \text{D}_n}(yw)$.

Finally, we need to compute $d\mu_{\text{T}_n \text{D}_n}$. To do so, note that $(yw)(y'w') = (y(ywy'^{-1}))(ww')$. Since $\text{D}_n$ normalizes $\text{T}_n$ (i.e. $w^{-1}yw \in \text{T}_n$, whenever $w \in \text{D}_n$ and $y \in \text{T}_n$), we can view $\text{T}_n \text{D}_n$ as a semidirect product $\text{T}_n \rtimes \text{D}_n$, with $w \in \text{D}_n$ acting on $y \in \text{T}_n$ by $w \cdot y = wwy^{-1}$. Therefore, by standard results in semidirect products of groups (e.g. see Section 1.2 of [44]), we have $d\mu_{\text{T}_n \text{D}_n}(yw) = \delta(w)^{-1}d\mu_{\text{T}_n}(y) d\mu_{\text{D}_n}(w)$, where $\delta : \text{D}_n \to \mathbb{R}^+$ satisfies

$$\int_{\text{T}_n} f(y) d\mu_{\text{T}_n}(y) = \delta(w) \int_{\text{T}_n} f(wwy^{-1}) dy, \quad \text{for every } f \in C_c(\text{T}_n) \text{ and } w \in \text{D}_n.$$

One can easily see that $d\mu_{\text{D}_n}(w) = \prod_{i=1}^{n-1} \frac{dw_i}{w_i}$ and $d\mu_{\text{T}_n}(y) = \prod_{i<j} dy_{i,j}$, with matrices $w$ and $y$ as represented in the statement of the theorem. Given that $wwy^{-1} = [y'_{i,j}] \in \text{T}_n$ with $y'_{i,j} = \frac{w_i y j}{w_j}$, we have $\delta(w) = \prod_{1 \leq i < j \leq n} \frac{w_j}{w_i}$. We can compute $\delta$ by a simple counting argument, and using the fact that $w_n = (w_1 \cdots w_{n-1})^{-1}$, as follows,

$$\delta(w) = \prod_{1 \leq i < j \leq n} \frac{w_j}{w_i} = \prod_{1 \leq i \leq n} \frac{w_{i-1}}{w_i} \prod_{1 \leq i \leq n} w_{2i-n-1} = \prod_{1 \leq i \leq n-1} w_{2i-2n}.$$

Putting all these together, we obtain the Haar measure of $\text{GL}_n(\mathbb{R})$, when the decomposition $\text{GL}_n(\mathbb{R}) = \mathbb{R}^+ \text{T}_n \text{D}_n \text{O}_n$ is used:

$$\lambda_{\text{GL}_n(\mathbb{R})}(E) = \int_{\mathbb{R}^+ \times \text{T}_n \times \text{D}_n \times \text{O}_n} 1_E(sywk) \prod_{i=1}^{n-1} w_i^{2i-2n} ds \prod_{i=1}^{n-1} \frac{dw_i}{w_i} \prod_{i<j} dy_{i,j}.$$

Finally, applying inverse map to the above formula and using unimodularity of $\text{GL}_n(\mathbb{R})$, we get

$$\lambda_{\text{GL}_n(\mathbb{R})}(E) = \int_{\mathbb{R}^+ \times \text{O}_n \times \text{D}_n \times \text{T}_n} \mathbf{1}_E(s^{-1}k^{-1}w^{-1}y^{-1}) \prod_{i=1}^{n-1} w_i^{2i-2n} dk \prod_{i=1}^{n-1} \frac{dw_i}{w_i} \prod_{i<j} dy_{i,j}.$$

$$= \int_{\mathbb{R}^+ \times \text{O}_n \times \text{D}_n \times \text{T}_n} \mathbf{1}_E(skw) \prod_{i=1}^{n-1} w_i^{-2i+2n} ds \prod_{i=1}^{n-1} \frac{dw_i}{w_i} \prod_{i<j} d(-y_{i,j}).$$

We now extend the tiling system originally constructed in [37] for $\text{GL}_2(\mathbb{R})$ to $\text{GL}_n(\mathbb{R})$.
Let $F$ be the set
\[
F = \left\{ \begin{pmatrix}
  w_1 & w_1 y_{1,2} & \cdots & w_1 y_{1,n-1} & w_1 y_{1,n} \\
  w_2 & w_2 y_{2,3} & \cdots & w_2 y_{2,n-1} & w_2 y_{2,n} \\
  w_3 & \ddots & \ddots & \ddots & \ddots \\
  \vdots & & \ddots & \ddots & \ddots \\
  w_n & \cdots & \cdots & \cdots & w_n y_{n-1,n,n} \\
  s & w_i & \cdots & w_i y_{i,n-1,n} & w_i y_{i,n-1,n} \\
\end{pmatrix} \right| s, w_i \in [1, 2], y_{i,j} \in [0, 1), k \in O_n \}
\]
and let $P$ be the discrete set
\[
P = \left\{ \begin{pmatrix}
  2^{\lambda_1} & 2^{\lambda_2} \mu_{1,2} & \cdots & 2^{\lambda_{n-1}} \mu_{1,n-1} & 2^{\lambda_n} \mu_{1,n} \\
  2^{\lambda_2} \mu_{2,3} & \cdots & \cdots & \cdots & \cdots \\
  \vdots & \ddots & \ddots & \ddots & \ddots \\
  \vdots & & \ddots & \ddots & \ddots \\
  2^{\lambda_{n-1}} & \cdots & \cdots & \cdots & 2^{\lambda_n} \mu_{n-1,n} \\
\end{pmatrix} \right| \lambda, \kappa_i, \mu_{i,j} \in \mathbb{Z} \}
\]
where $\kappa_n = -\sum_{i=1}^{n-1} \kappa_i$.

**Proposition 4.2.** For $F$ and $P$ as above, the following two properties hold:

1. $F \cdot p \cap F \cdot q = \emptyset$ for every $p \neq q \in P$.
2. $\bigcup_{p \in P} F \cdot p = \text{GL}_n(\mathbb{R})$.

**Proof.** Again, for simplicity of notation, let $w_n = \prod_{i=1}^{n-1} w_i^{-1}$. Now, to establish the claim, we show that for each $a \in \text{GL}_n(\mathbb{R})$, the equation
\[
a = sk \begin{pmatrix}
  w_1 & \cdots & w_1 y_{1,n-1} & w_1 y_{1,n} \\
  \vdots & \ddots & \ddots & \ddots \\
  w_n & \cdots & \cdots & \cdots \\
  s & w_i & \cdots & w_i y_{i,n-1,n} \\
\end{pmatrix} 2^\lambda \begin{pmatrix}
  2^{\lambda_1} & \cdots & 2^{\lambda_{n-1}} \mu_{1,n-1} & 2^{\lambda_n} \mu_{1,n} \\
  \vdots & \ddots & \ddots & \ddots \\
  \vdots & & \ddots & \ddots \\
  2^{\lambda_{n-1}} & \cdots & \cdots & 2^{\lambda_n} \mu_{n-1,n} \\
\end{pmatrix}
\]
has a unique solution subject to the constraints $\lambda, \kappa_i, \mu_{i,j} \in \mathbb{Z}, s, w_i \in [1, 2], y_{i,j} \in [0, 1)$.

First note that by uniqueness of Iwasawa decomposition, the element $k \in O_n$ in the above equation is unique. Moreover, from (8) we have $|\det(a)| = (s2^\lambda)^n$, and it is easy to see that there are unique $s \in [1, 2]$ and $\lambda \in \mathbb{Z}$ which satisfy this equation. Indeed, this is a consequence of the fact that $([1, 2], \mathbb{Z})$ is a tiling system for $(0, \infty)$.

Let $a' = \frac{1}{|\det(a)|^{1/n}} k^{-1} a$. (Note that at this point $k$ is uniquely determined.) Clearly, $a'$ is upper triangular with determinant 1, and we are left to show that
\[
a' = \begin{pmatrix}
  w_1 & \cdots & w_1 y_{1,n-1} & w_1 y_{1,n} \\
  \vdots & \ddots & \ddots & \ddots \\
  w_n & \cdots & \cdots & \cdots \\
  s & w_i & \cdots & w_i y_{i,n-1,n} \\
\end{pmatrix} 2^\lambda \begin{pmatrix}
  2^{\lambda_1} & \cdots & 2^{\lambda_{n-1}} \mu_{1,n-1} & 2^{\lambda_n} \mu_{1,n} \\
  \vdots & \ddots & \ddots & \ddots \\
  \vdots & & \ddots & \ddots \\
  2^{\lambda_{n-1}} & \cdots & \cdots & 2^{\lambda_n} \mu_{n-1,n} \\
\end{pmatrix}
\]
has a unique solution given the constraints $w_i \in [1, 2], y_{i,j} \in [0, 1), \kappa_i, \mu_{i,j} \in \mathbb{Z}$. To do so, we denote the product of the two matrices on the right hand side of (9) as $z = [z_{i,j}]$, and we observe that these
entries have the form

\[
z_{i,j} = \begin{cases} 
0, & \text{for } j - i < 0, \\
w_i 2^{\kappa_i}, & \text{for } j - i = 0, \\
w_i 2^{\kappa_i} (y_{i,j} + \mu_{i,j}), & \text{for } j - i = 1, \\
w_i 2^{\kappa_i} (y_{i,j} + \sum_{k=i+1}^{j-1} y_{i,k} \mu_{k,j}) & \text{for } j - i > 1
\end{cases}
\]

We now proceed by an induction-like argument on the diagonals, starting from the main diagonal. Namely, note that \(a_{i,i} = 2^{\kappa_i} w_i\), with constraints \(w_i \in [1, 2)\) and \(\kappa_i \in \mathbb{Z}\), has a unique solution for each \(1 \leq i \leq n\). Moving to the super-diagonal, we likewise solve these equations to find that when \(j - i = 1\), we have

\[
\mu_{i,j} = \left[ \frac{2^{-\kappa_i} a_{i,j}'}{w_i} \right], \quad \text{and} \quad y_{i,j} = \frac{2^{-\kappa_i} a_{i,j}'}{w_i} - \left[ \frac{2^{-\kappa_i} a_{i,j}'}{w_i} \right].
\]

Finally, the remaining entries when \(j - i > 1\) can be computed similarly, as follows.

\[
\mu_{i,j} = \left[ \frac{2^{-\kappa_i} a_{i,j}'}{w_i} \right] - \sum_{k=i+1}^{j-1} y_{i,k} \mu_{k,j}, \quad \text{and} \quad y_{i,j} = \frac{2^{-\kappa_i} a_{i,j}'}{w_i} - \left[ \frac{2^{-\kappa_i} a_{i,j}'}{w_i} \right] - \sum_{k=i+1}^{j-1} y_{i,k} \mu_{k,j}
\]

where all values on the right hand sides are known from previous diagonals. This establishes the proposition. \(\square\)

Note that this proves that the pair \((P,F)\) forms a frame generator in the sense of [9], and the pair \((F,P)\) satisfies the slightly different definition of a tiling system given in [37]. We now show that \((F,P)\) also fulfills the new conditions for a tiling system given in Definition 3.1.

**Corollary 4.3.** For \(F\) and \(P\) as given in the previous proposition, we have

(i) \(\lambda_{\text{GL}_n}(F \cdot p \cap F \cdot q) = 0\) for every distinct pair \(p, q \in P\),

(ii) \(\lambda_{\text{GL}_n}(\text{GL}_n(\mathbb{R}) \setminus \bigcup \{F \cdot p : p \in P\}) = 0\).

**Proof.** Property (ii) is immediate, as \(\text{GL}_n(\mathbb{R}) = \bigcup \{F \cdot p : p \in P\} \subseteq \bigcup \{\overline{F} \cdot p : p \in P\} \subseteq \text{GL}_n(\mathbb{R})\).

For the first property, note that by Proposition 4.2, \(F \cdot p \cap F \cdot q = \emptyset\) if \(p \neq q \in P\). So,

\[
\lambda_{\text{GL}_n(\mathbb{R})}(F \cdot p \cap F \cdot q) = \lambda_{\text{GL}_n(\mathbb{R})}((F \setminus F) \cdot p \cap F \cdot q) \cup (F \setminus F) \cdot q \cap F \cdot p))
\leq \lambda_{\text{GL}_n(\mathbb{R})}((F \setminus F) \cdot p) + \lambda_{\text{GL}_n(\mathbb{R})}((F \setminus F) \cdot q)
= \lambda_{\text{GL}_n(\mathbb{R})}(F \setminus F) + \lambda_{\text{GL}_n(\mathbb{R})}(F \setminus F)
= 0,
\]

where the second to last equality follows as \(\text{GL}_n(\mathbb{R})\) is unimodular, and the last equality can easily be computed directly by Theorem 4.1. \(\square\)
An Open Set $F_o \supset \overline{F}$. Fix $\epsilon > 0$. Let $F_o$ be the set

$$F_o = \left\{ \begin{pmatrix} w_1 & w_1y_{1,2} & \cdots & w_1y_{1,n-1} & w_1y_{1,n} \\ w_2 & w_2y_{2,3} & \cdots & w_2y_{2,n-1} & w_2y_{2,n} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ w_{n-1} & w_{n-1}y_{n-1,n} & \cdots & w_{n-1}y_{n-1,1} & w_{n-1} \\ \prod_{i=1}^{n-1} w_i^{-1} \end{pmatrix} \left| \begin{array}{c} s, w_i \in (1 - \epsilon, 2 + \epsilon), \\ y_{i,j} \in (-\epsilon, 1 + \epsilon), \\ k \in O_n \end{array} \right. \right\}.$$  

**Claim 4.4.** $F_o$ is an open set in $GL_n(\mathbb{R})$ such that $\overline{F} \subseteq F_o$.

**Proof.** The inclusion $\overline{F} \subseteq F_o$ is clear. To prove that $F_o$ is open in $GL_n(\mathbb{R})$, note that the multiplication map

$$SO_n \times D_n \times T_n \to SL_n(\mathbb{R})$$

is a diffeomorphism (see Proposition 1.6.2 of [45]). So, $\mathbb{R}^+ \times O_n \times D_n \times T_n \to GL_n(\mathbb{R})$ is a homeomorphism, and maps any open set to an open subset of $GL_n(\mathbb{R})$. \qed

Summarizing the results from this section, we have constructed a tiling system $(F, P)$ and determined how to compute the measure of a set $E$ through the coordinates of the Iwasawa decomposition, which we used to motivate the tiling. We now use these results to compute frame bounds for the discretization of the continuous wavelet transform.

### 5. Computation of Frame Bounds

In this section, we find bounds for the value $M$ (as defined for Theorem 3.6) associated with the sets $P, F$, and $F_o$. Recall that $M$ is just the least uniform upper bound for the number of $q \in P$ such that for a fixed $p \in P$, $\overline{F} \cdot p$ and $F_o \cdot q$ have nontrivial intersection. Once we have done this for general $n$, we provide a concrete example with all details when $n = 2$.

**Notation 5.1.** From this point forward, we use $\text{diag}(w_1, \ldots, w_n)$ to denote an $n \times n$ diagonal matrix with diagonal entries $w_1, \ldots, w_n$.

**Proposition 5.2.** For $F, P$, and $F_o$ as defined before, $M$ as in Notation 3.5, and $0 < \epsilon \leq \frac{1}{2}$, we have

$$M = \sup_{p \in P} \left| \left\{ k \in P : \overline{F} \cdot p \cap F_o \cdot k \neq \emptyset \right\} \right| \leq 3^n 6^{\frac{n(n-1)}{2}}.$$  

**Proof.** If $\overline{F} \cdot p \cap F_o \cdot p' \neq \emptyset$ for some $p \neq p' \in P$, then there exist $a \in \overline{F}$ and $a' \in F_o$ for which we have $ap = a'p'$, or equivalently

$$a = a'p'p^{-1}. \tag{10}$$

Using Theorem 4.1, we write the Iwasawa decompositions $a = skwy$ and $a' = s'k'w'y'$, where $w$ and $w'$ are diagonal matrices $\text{diag}(w_1, \ldots, w_{n-1}, w_1 \cdots w_{n-1})^{-1}$ and $\text{diag}(w'_1, \ldots, w'_{n-1}, (w'_1 \cdots w'_{n-1})^{-1})$, and $y = [y_{i,j}]$ and $y' = [y'_{i,j}]$ are unit upper triangular matrices. Suppose $p, p'$ are written in the format of $P$ using $\lambda, \kappa_i, \mu_{i,j}$ and $\lambda', \kappa'_{i,j}, \mu'_{i,j}$ respectively. By the uniqueness of Iwasawa decomposition and equality of the determinants of both sides of the above equation, we get:

(C1) \hspace{1cm} k = k', \\

(C2) \hspace{1cm} s = s'2^{\lambda'-\lambda}. \tag{C2}
From Equation (10), we get
\[
wy = w'y' [\mu_{i,j}'] \text{diag}(2^{\kappa'_i - \kappa_1}, \ldots, 2^{\kappa'_{n} - \kappa_n}) [\mu_{i,j}]^{-1},
\]
which simplifies to
\[
wy = \underbrace{w' \text{diag}(2^{\kappa'_i - \kappa_1}, \ldots, 2^{\kappa'_{n} - \kappa_n})}_{\in \mathbb{D}_n} \underbrace{\text{diag}(2^{-\kappa'_i + \kappa_1}, \ldots, 2^{-\kappa'_{n} + \kappa_n}) y' [\mu_{i,j}'] \text{diag}(2^{\kappa'_i - \kappa_1}, \ldots, 2^{\kappa'_{n} - \kappa_n}) [\mu_{i,j}]^{-1}}_{\in \mathbb{T}_n},
\]
where \(y, y', [\mu_{i,j}'], [\mu_{i,j}] \in \mathbb{T}_n\) are unit upper triangular matrices, and \(\sum_{i=1}^{n} \kappa_i = \sum_{i=1}^{n} \kappa'_i = 0\) (as in the definition of \(P\)). Note that in the above equation, we used the fact that \(\mathbb{D}_n\) normalizes \(\mathbb{T}_n\). By uniqueness of Iwasawa decomposition, we have
\[
w = w' \text{diag}(2^{\kappa'_i - \kappa_1}, \ldots, 2^{\kappa'_{n} - \kappa_n}),
\]
and
\[
[y_{i,j}] = \text{diag}(2^{-\kappa'_i + \kappa_1}, \ldots, 2^{-\kappa'_{n} + \kappa_n}) [y'_{i,j}] [\mu_{i,j}'] \text{diag}(2^{\kappa'_i - \kappa_1}, \ldots, 2^{\kappa'_{n} - \kappa_n}) [\mu_{i,j}]^{-1}.
\]
Thus we obtain the conditions
\[
\begin{align*}
(C3) && w'_i 2^{\kappa'_i - \kappa_i} = w_i & \forall i \\
(C4) && 2^{(\kappa'_j - \kappa_j) - (\kappa'_i - \kappa_i)} \sum_{k=i}^{j} y'_{i,k} \mu'_{k,j} = \sum_{k=i}^{j} y_{i,k} \mu_{k,j} & \text{for } j \geq i
\end{align*}
\]
by comparing each product entry-wise.

Given a fixed \(p \in P\) represented by \(\lambda, \kappa_i, \mu_{i,j}\), we count the number of \(p' \in P\) with parameters \(\lambda', \kappa'_i, \mu'_{i,j}\) for which Equation (11) can be satisfied for some choice of \(a \in \mathbb{F}\) and \(a' \in \mathbb{F}_0\). Using condition (C1), we see that
\[
s'2^{\lambda' - \lambda} = s \in [1, 2].
\]
As \(s' \in (1 - \epsilon, 2 + \epsilon)\), we deduce that \(\lambda' - \lambda \in \{-1, 0, 1\}\) if \(\epsilon \leq \frac{1}{2}\). This also shows that \(\lambda' - \lambda = -1\) implies \(s' \in [2, 2 + \epsilon)\), \(\lambda' - \lambda = 0\) implies \(s' \in [1, 2]\), and finally that \(\lambda' - \lambda = 1\) implies that \(s' \in (1 - \epsilon, 1]\). Similarly, we deduce from (C3) that \(\kappa'_i - \kappa_i \in \{-1, 0, 1\}\) holds when \(\epsilon \leq \frac{1}{2}\). This constrains \(w'_i\) to be in \([2, 2 + \epsilon)\), \([1, 2]\) or \((1 - \epsilon, 1]\) respectively. Also, note that for a given choice of \(\kappa'_i \in \{\kappa_i - 1, \kappa_i, \kappa_i + 1\}\), we have a uniquely determined \(w'_i\) given by \(w'_i = \frac{w_i}{2^{\kappa'_i - \kappa_i}}\).

From this point forward, we assume that \(\lambda'\) and \(\kappa'_1, \ldots, \kappa'_{n-1}\) have been chosen according to the above constraints, and the parameters \(s', w'_i\) and \(\kappa'_n\) have been determined accordingly; recall that \(\kappa'_n = -\sum_{i=1}^{n-1} \kappa'_i\). Let \(p_{i,j} = (\kappa'_j - \kappa_j) - (\kappa'_i - \kappa_i)\). As \(\kappa'_j - \kappa_j, \kappa'_i - \kappa_i \in \{-1, 0, 1\}\), it follows that \(p_{i,j} \in \{-2, -1, 0, 1, 2\}\). To count possible solutions for equations, we will make repeated use of the following claim.

**Claim 5.3.** Let \(\epsilon \leq \frac{1}{2}\) be fixed. Then for any interval \([\alpha, \alpha + 4] \subset \mathbb{R}\), there are at most six \(\beta \in \mathbb{Z}\) such that \([\alpha, \alpha + 4] \cap (\beta - \epsilon, \beta + 1 + \epsilon) \neq \emptyset\).

**Proof of claim.** Let \(m = \text{min}\{\beta \in \mathbb{Z} : [\alpha, \alpha + 4] \cap (\beta - \epsilon, \beta + 1 + \epsilon) \neq \emptyset\}\). Clearly \(m\) exists and is finite, as both intervals are bounded and \(\mathbb{Z}\) is discrete. Now, consider \(m+k\) for \(k \geq 6\). If \((m+k-\epsilon, m+k+1+\epsilon)\) intersects \([\alpha, \alpha + 4]\), then we have \((m-\epsilon, m+1+\epsilon)\) intersects \([\alpha-k, \alpha-k+4]\). On the other hand, by definition of \(m\), we know that \((m-\epsilon, m+1+\epsilon)\) intersects \([\alpha, \alpha + 4]\) as well. This is a contradiction, because \((m-\epsilon, m+1+\epsilon)\) has length at most 2, which is not larger than the gap between the above
two closed intervals. Therefore, there are at most 6 possible choices for \( \beta \in \mathbb{Z} \) for which we may have \([\alpha, \alpha + 4] \cap (\beta - \epsilon, \beta + 1 + \epsilon) \neq \emptyset\).

We now proceed by an inductive argument, examining diagonals of the matrices on the two sides of Equation (C4), starting from the super-diagonal. For \( j = i + 1 \), condition (C4) becomes

\[
y'_{i,i+1} + \mu'_{i,i+1} = 2^{-p_{i,i+1}} (\mu_{i,i+1} + y_{i,i+1}),
\]

with the constraints \( y'_{i,i+1} \in (-\epsilon, 1+\epsilon), y_{i,i+1} \in [0,1] \) and \( \mu'_{i,i+1} \in \mathbb{Z} \). Note that \( 2^{-p_{i,i+1}} \mu_{i,i+1} \) is fixed at this point, and clearly \( 2^{-p_{i,i+1}} y_{i,i+1} \in [0,4] \). So by Claim 5.3, there are at most six possible choices for \( \mu'_{i,i+1} \). This settles the discussion for the superdiagonal.

Next, by induction hypothesis, assume that for every \( \mu'_{i,j} \) with \( j-i < k \), there are at most six possible choices that satisfy Equation (C4). Also assume that \( y_{i,j}, y'_{i,j} \) and \( \mu_{i,j} \) have been fixed whenever \( j-i < k \) (i.e. for the first \( k-1 \) diagonals). For \( j = i + k \), condition (C4) becomes

\[
y'_{i,i+k} + \mu'_{i,i+k} = 2^{-p_{i,i+k}} y_{i,i+k} + \left( 2^{-p_{i,i+k}} \sum_{t=i}^{k+i-1} y_{i,t} \mu_{t,i+k} - \sum_{t=i+1}^{k+i} y'_{i,t} \mu'_{t,i+k} \right) \alpha,
\]

where \( \mu'_{i,i+k} \in \mathbb{Z}, y'_{i,i+k} \in (-\epsilon, 1+\epsilon) \) and \( y_{i,i+k} \in [0,1] \). Note that the expression \( \alpha \) in the above equation is fixed, as it only involves values which have already been chosen. So, by Claim 5.3, there are at most six possible choices for \( \mu'_{i,i+k} \). This proves that for every \( \mu'_{i,j} \) in Equation (C4), there are only six possible values that may satisfy the equation.

In the following table, we summarize what we have found so far. Note that not every possible solution is necessarily an actual solution; however, any solution for (C4) is counted below.

| parameter | number of possible choices | possible solutions in terms of \( p' \) |
|-----------|--------------------------|-----------------------------------------|
| \( \lambda' \) | 3 | \( \lambda - 1, \lambda, \lambda + 1 \) |
| \( \kappa'_{i,j}, 1 \leq i < n \) | 3 | \( \kappa_{i-1}, \kappa_{i}, \kappa_{i} + 1 \) |
| \( \kappa'_{n} \) | 1 | \( -\sum_{i=1}^{n-1} \kappa'_{i} \) |
| \( \mu'_{i,j}, i < j \) | 6 | solutions to Equation (12) satisfying the given constraints |

Table 1. Maximum number of possible choices for each parameter in \( p' \).

Combing these results, we conclude that for a fixed \( p \in P \), there are at most \( 3^{n}6^{\frac{n(n-1)}{2}} \) possible choices for \( p' \in P \) such that \( F \cdot p \cap F' \cdot p' \neq \emptyset \).

**Remark 5.4.** When \( n = 2 \), the above proposition gives \( M \leq 54 \). This case was also previously studied in [37]. Proposition 5.2, together with Theorem 3.6, shows that using our methods one can construct frames with significantly better frame condition numbers than the construction in [37]. Indeed, the ratio of the frame bounds in our construction is \( \frac{C_2}{\alpha} \leq 54 \), whereas the frame condition number for the construction in [37] was \( \frac{C_2}{\alpha} \sim 1782 \). (In fact, it is only mentioned in [37] that \( M < \infty \). However, looking into their arguments closely, one can obtain the bound \( M \sim 1782 \). Also, note that there is a typo in the definition of \( M \) in [37]; the correct formula should be \( M = \sup_{p \in P} \{ \|p' \cdot p \| : p \cdot D \cap p' \cdot D \neq \emptyset \} \). As the rate of convergence in frame calculations when approximating signals is highly sensitive to the frame condition number (i.e. the ratio of the frame bounds), our methods result in much more practical and efficient frames than those of [37] for the case of \( n = 2 \).
6. Concrete Frame Construction for $n = 2$

So far, we have established that the proposed sets $F, F_0,$ and $P$ satisfy the conditions of Theorem 3.6, and have calculated $M$ as well. In this section, we use these sets and follow the construction in Theorem 3.6, to give an explicit example of a discrete frame for $L^2(M_2(\mathbb{R}))$. A similar approach can be taken for higher dimensions, but we focus our attention on $n = 2$ for now.

The Iwasawa decomposition for $\text{GL}_2(\mathbb{R})$ can be stated as follows: Let $O_2$ denote the group of orthogonal $2 \times 2$ matrices, $D_2$ denote the diagonal $2 \times 2$ matrices with positive diagonal entries and determinant 1, and $T_2$ denote the $2 \times 2$ unit upper triangular matrices. Every element of $\text{GL}_2(\mathbb{R})$ can be uniquely decomposed as an ordered product of elements in $O_2, D_2,$ and $T_2$. That is, $\text{GL}_2(\mathbb{R}) = O_2 D_2 T_2$. Note that $O_2$ is compact, and $T_2$ and $D_2$ are both abelian subgroups of $\text{GL}_2(\mathbb{R})$.

Tiling System. Let $P = \left\{ 2^\lambda \begin{pmatrix} 2^\kappa & 2^{-\kappa} \mu \\ 0 & 2^{-\kappa} \end{pmatrix} : \lambda, \kappa, \mu \in \mathbb{Z} \right\}$, $F = \left\{ \begin{pmatrix} \pm \cos \theta & \mp \sin \theta \\ \sin \theta & \cos \theta \end{pmatrix} \begin{pmatrix} s \omega & s\omega y \\ s \omega & s \omega^{-1} \end{pmatrix} : \theta \in [0,2\pi), s, w \in [1,2), y \in [0,1) \right\}$.

Then $(F, P)$ forms a tiling system in the sense of Definition 3.1 for $\text{GL}_2(\mathbb{R})$. After projecting on the $(s, w, y)$-space, this tile and some of its translates under the action of $P$ are shown in Figure 1. Note that by Proposition 5.2, we have $M \leq 54$. 

Figure 1. Multiscale tiling based on $(F, P)$. The base tile is lighter. Several shifted tiles are shown in darker gray.
As before, we take $0 < \epsilon \leq \frac{1}{2}$, and define $F_o$ to be

$$F_o = \left\{ \left( \frac{\pm \cos \theta}{\sin \theta} \pm \sin \theta \right) \left( \begin{array}{c} sw \\ sw^{-1} \end{array} \right) \left\{ \begin{array}{c} \theta \in [0, 2\pi) \\ s, w \in (1 - \epsilon, 2 + \epsilon) \\ y \in (-\epsilon, 1 + \epsilon) \end{array} \right\} \right\}. \tag{14}$$

Reconstruction Formula. Now, we recall the explicit formulation of the reconstruction formula (6) for $n = 2$. The wavelet condition (Equation (13)) and reconstruction formula (Equation (14)) were obtained in Theorem 2.1 of [37].

Let $\psi \in L^2(\mathbb{R}^4)$. If

$$\int_{\mathbb{R}^4} |\tilde{\psi}(h_1, h_2, h_3, h_4)|^2 \frac{dh_1 dh_2 dh_3 dh_4}{|h_1 h_4 - h_2 h_3|^2} = 1, \tag{13}$$

then $\psi$ is a wavelet. For $x, y \in M_2(\mathbb{R})$ and $h \in \text{GL}_2(\mathbb{R})$, define

$$\psi_{x, h}(y) = \frac{1}{|h_1 h_4 - h_2 h_3|} \psi \left( \frac{h_1 h_4 - h_2 h_3}{h_1 h_4 - h_2 h_3} \frac{h_1(y_1 - x_1) - h_2(y_2 - x_2) - h_3(y_3 - x_3) - h_4(y_4 - x_4)}{h_1 h_4 - h_2 h_3} \right).$$

Then, for any $f \in L^2(\mathbb{R}^4)$, we have

$$f = \int_{\mathbb{R}^4} \int_{\mathbb{R}^4} \langle f, \psi_{x, h} \rangle \psi_{x, h} \frac{dx_1 \cdots dx_4 dh_1 \cdots dh_4}{|h_1 h_4 - h_2 h_3|^4}, \tag{14}$$

weakly in $L^2(\mathbb{R}^4)$. Conversely, if (14) holds for every $f \in L^2(\mathbb{R}^4)$, then $\psi$ is a wavelet.

Next, we discretize this reconstruction formula to make it computationally feasible. The Discrete Frame. To discretize the above continuous frame, we find a 4-dimensional cube $R$ containing $F_o$. Suppose

$$R = \{(x_1, x_2, x_3, x_4) : x_i \in [a_i, b_i] \quad \text{for} \quad i \in \{1, 2, 3, 4\}\},$$

where $a_i < b_i$, for $1 \leq i \leq 4$, are fixed real numbers. We need to determine appropriate values for $a_i$ and $b_i$ so that $F_o \subseteq R$. Consider an arbitrary element of $F_o$ together with its Iwasawa decomposition, say

$$\left( \begin{array}{c} x_1 \\ x_2 \\ x_3 \\ x_4 \end{array} \right) = \left( \frac{\pm \cos \theta}{\sin \theta} \pm \sin \theta \right) \left( \begin{array}{c} sw \\ sw^{-1} \end{array} \right),$$

where $s, w \in (1 - \epsilon, 2 + \epsilon)$ and $y \in (-\epsilon, 1 + \epsilon)$. Comparing the two sides of the above matrix equation, we get

$$|x_1|, |x_3| \leq |sw| \leq (2 + \epsilon)^2 < 7,$$

$$|x_2|, |x_4| < \sqrt{|sw|^2 + \frac{2}{w}} \leq (2 + \epsilon)(1 + \epsilon) \sqrt{w^2 + \frac{1}{w^2}} \leq (2.5)(1.5)\sqrt{6.5} < 10,$$

where we used the fact that $\epsilon \leq \frac{1}{2}$. Thus, we can set $a_1 = a_3 = -7$, $b_1 = b_3 = 7$, $a_2 = a_4 = -10$, and $b_2 = b_4 = 10$.

Let $L^2(R)$ be the closed subspace of $L^2(\mathbb{R}^4)$ consisting of all the elements supported on $R$. We can construct an orthonormal basis of $L^2(R)$ indexed by the set $J$ defined as

$$J = \left\{ \lambda = \left( \begin{array}{c} \lambda_1 \\ \lambda_2 \\ \lambda_3 \\ \lambda_4 \end{array} \right) \bigg| \lambda_1, \lambda_3 \in \frac{1}{14} \mathbb{Z}, \ \lambda_2, \lambda_4 \in \frac{1}{20} \mathbb{Z} \right\}. \tag{17}$$
Then for all $g \in L^2(M_2(\mathbb{R}))$ which satisfy $\|f\| \leq \hat{g} \leq \|f\|$, we have

$$\{\rho[\lambda,p]^{-1}g : (\lambda,p) \in J \times P\}$$

is a discrete frame with frame bounds $C_1 = |R|, C_2 = |R|M$. That is

$$|R| \|f\|^2 \leq \sum_{k \in P} \sum_{\gamma \in J} |\langle f, \rho[\gamma,k]^{-1}g \rangle_{L^2(M_2(\mathbb{R}))}|^2 \leq |R|M \|f\|^2$$

for all $f \in L^2(M_2(\mathbb{R}))$. If necessary or useful, it is easy to explicitly compute $\rho[\lambda,p]^{-1}g$, with a formula similar to $\psi_{x,h} = \rho[x,h] \psi$ (which was explicitly computed previously).

**Remark 6.1.** Note that $|R|$ in the above construction is $14^2 \times 20^2$, which is by far smaller than the similar parameter from [37], which was $176^4$.

7. **Future Directions**

In future work, we will construct similar frames for the Hilbert space of Sobolev functions $H^k(\mathbb{R}^n)$. We expect that the regularity conditions will provide additional control over the frame bounds. This should result in a much smaller frame ratio, which we expect to be dependent on $\epsilon$; as opposed to the current construction for which the frame bounds are independent of parameter $\epsilon$. In particular, we expect to see direct relations between how small the frame ratio is and how much regularity can be assumed on the signals of interest.

8. **Acknowledgements**

This project was initiated during a summer research program funded by University of Delaware Graduate Program Improvement and Innovation Grants “GEMS”. The second author thanks University of Delaware for funding his GEMS project in summer 2016 and summer 2018. The first author was partially supported by University of Delaware Research Foundation, and partially by NSF grant DMS-1902301, while this work was being completed. She also thanks the Department of Mathematical Sciences at Delaware for its support while important revisions were made to the paper. Finally, the authors would like to thank Nathaniel Kim and Paige Shumskas for proofreading this work.
