Manifolds with parallel differential forms and Kähler identities for $G_2$-manifolds

Misha Verbitsky

verbit@maths.gla.ac.uk, verbit@mccme.ru

Abstract
Let $M$ be a compact Riemannian manifold equipped with a parallel differential form $\omega$. We prove a version of Kähler identities in this setting. This is used to show that the de Rham algebra of $M$ is weakly equivalent to its subquotient $(H^c_*(M), d)$, called the pseudocohomology of $M$. When $M$ is compact and Kähler and $\omega$ is its Kähler form, $(H^c_*(M), d)$ is isomorphic to the cohomology algebra of $M$. This gives another proof of homotopy formality for Kähler manifolds, originally shown by Deligne, Griffiths, Morgan and Sullivan. We compute $H^c_*(M)$ for a compact $G_2$-manifold, showing that $H^c_*(M) \cong H^i(M)$ unless $i = 3, 4$. For $i = 3, 4$, we compute $H^c_*(M)$ explicitly in terms of the first order differential operator $*d : \Lambda^3(M) \to \Lambda^3(M)$.

1 Introduction

1.1 Holonomy groups in Riemannian geometry

Let $M$ be a Riemannian manifold equipped with a differential form $\omega$. This form is called parallel if $\omega$ is preserved by the Levi-Civita connection: $\nabla \omega = 0$. This identity gives a powerful restriction on the holonomy group $\mathcal{H}ol(M)$.

The structure of $\mathcal{H}ol(M)$ and its relation to geometry of a manifold is one of the main subjects of Riemannian geometry of last 50 years. This group is compact, hence reductive, and acts, in a natural way, on the tangent space $TM$. When $M$ is complete, Georges de Rham proved that unless this representation is irreducible, $M$ has a finite covering, which is a product of Riemannian manifolds of smaller dimension ([R]). Irreducible holonomies were classified by M. Berger ([Ber]), who gave a complete list of all irreducible holonomies which can occur on non-symmetric spaces. This list is quite short:

| Holonomy | Geometry                      |
|----------|-------------------------------|
| $SO(n)$ acting on $\mathbb{R}^n$ | Riemannian manifolds          |
| $U(n)$ acting on $\mathbb{C}^n$  | Kähler manifolds              |
| $SU(n)$ acting on $\mathbb{C}^{2n}$, $n > 2$ | Calabi-Yau manifolds          |
| $Sp(n)$ acting on $\mathbb{R}^{4n}$ | hyperkähler manifolds         |
| $Sp(n) \times Sp(1)/\{\pm 1\}$ acting on $\mathbb{R}^{4n}$, $n > 1$ | quaternionic-Kähler manifolds |
| $G_2$ acting on $\mathbb{R}^7$ | $G_2$-manifolds               |
| $Spin(7)$ acting on $\mathbb{R}^8$ | $Spin(7)$-manifolds           |

Berger’s list also included $Spin(9)$ acting on $\mathbb{R}^{16}$, but D. Alekseevsky later observed that this case is impossible ([A]), unless $M$ is symmetric. If an irreducible manifold $M$ has a parallel differential form, its holonomy is restricted, as $SO(n)$ has no invariants in $\Lambda^i(TM), \ 0 < i < n$. Then $M$ is locally a product of symmetric spaces and manifolds with holonomy $U(n)$, $SU(n)$, $Sp(n)$, etc.
In Kähler geometry (holonomy $U(n)$) the parallel forms are the Kähler form and its powers. Studying the corresponding algebraic structures, the algebraic geometers amassed an amazing wealth of topological and geometric information. In this paper we try to generalize some of these results to other manifolds with a parallel form, especially the $G_2$-manifolds. The results thus obtained can be summarized as “Kähler identities for $G_2$-manifolds”.

1.2 $G_2$-manifolds in mathematics and physics

The theory of $G_2$-manifolds is one of the places where mathematics and physics interact most intensely. For many years after Berger’s groundbreaking results, this subject was dormant; after Alekseevsky showed that $Spin(9)$ cannot be realized in holonomy, there were doubts whether the other two exceptional entries in Berger’s list ($G_2$ and $Spin(7)$) can be realized.

Only in 1980-ies were manifolds with holonomy $G_2$ constructed. R. Bryant ([Br1]) found local examples, and then R. Bryant and S. Salamon found complete manifolds with holonomy $G_2$ ([BS]). The compact examples of holonomy $G_2$ and $Spin(7)$-manifolds were produced by D. Joyce ([J1], [J2]), using difficult (but beautiful and quite powerful) arguments from analysis and PDE theory. Since then, the $G_2$-manifolds became a central subject of study in some areas of string physics, and especially in M-theory. The mathematical study of $G_2$-geometry was less intensive, but still quite fruitful. Important results were obtained in gauge theory on $G_2$-manifold (the study of Donaldson-Thomas bundles): [DT], [T], [TT]. A. Kovalev found many new examples of $G_2$-manifolds, using a refined version of Joyce’s engine ([K]). N. Hitchin constructed a geometric flow ([Hi1], [Hi2]), which turned out to be extremely important in string physics (physicists call this flow Hitchin’s flow). Hitchin’s flow acts on the space of all “stable” (non-degenerate and positive) 3-forms on a 7-manifold. It is fixed precisely on the 3-forms corresponding to the connections with holonomy in $G_2$. In [DGNV], a unified theory of gravity is introduced, based in part on Hitchin’s flow. From the special cases of topological M-theory one can deduce 4-dimensional loop gravity, and 6-dimensional A- and B-models in string theory.

In string theory, $G_2$-manifolds are expected to play the same role as Calabi-Yau manifolds in the usual A- and B-model of type-II string theories. These two forms of string theory both use Calabi-Yau manifolds, in a different fashion. Duality between these theories leads to duality between Calabi-Yau manifolds, and then to far-reaching consequences, which were studied in mathematics and physics, under the name of Mirror Symmetry. During the last 20 years, the Mirror Symmetry became one of the central
topics of modern algebraic geometry.

There are two important ingredients in Mirror Symmetry (in Strominger-Yau-Zaslow form) - one counts holomorphic curves on one Calabi-Yau manifolds, and the special Lagrangian cycles on its mirror dual. Using $G_2$-geometry, these two kinds of objects (holomorphic curves and special Lagrangian cycles) are transformed into the same kind of objects, called **associative cycles** on a $G_2$-manifold. This is done as follows.

A $G_2$-structure on a 7-manifold is given by a 3-form (see Subsection 3.1). Consider a Calabi-Yau manifold $X$, dim $M = 3$, with non-degenerate holomorphic 3-form $\Omega$, and Kaehler form $\omega$. Let $M := X \times S^1$, and let $dt$ denote the unit cotangent form of $S^1$ lifted to $M$. Consider a 3-form $\omega \wedge dt + \text{Re} \Omega$ on $M$. This form is obviously closed. It is easy to check that it defines a parallel $G_2$-structure on $M$. This way one can convert problems from Calabi-Yau geometry to problems in $G_2$-geometry.

A 3-form $\varphi$ on a manifold $M$ gives an anti-symmetric map

$$\varphi^\#: TM \otimes TM \rightarrow \Lambda^1(M),$$

$x, y \mapsto \varphi(x, y, \cdot)$. Using the Riemannian structure, we identify $TM$ and $\Lambda^1(M)$. Then $\varphi^\#$ leads to a skew-symmetric vector product $V : TM \otimes TM \rightarrow TM$. An **associative cycle** on a $G_2$-manifold is a 3-dimensional submanifold $Z$ such that $TZ$ is closed under this vector product. Associative submanifolds are studied within the general framework of calibrated geometries (see [HL]).

Given a Calabi-Yau threefold $X$, consider $M = X \times S^1$ with a $G_2$-structure defined above. Let $Z \subset X$ be a 3-dimensional submanifold. It is easy to check that $Z$ is special Lagrangian if and only if $Z \times \{t\}$ is associative in $M$. Also, given a 2-cycle $C$ on $X$, $C \times S^1$ is associative in $M$ if and only if $C$ is a holomorphic curve. This way, the instanton objects in mirror dual theories (holomorphic curves and SpLag cycles) can be studied uniformly after passing to $G_2$-manifold. It was suggested that this correspondence indicates some form of string duality ([L], [SS]).

However, the main physical motivation for the study of $G_2$-manifolds comes from M-theory; we direct the reader to the excellent survey [AG] for details and further reading. M-theory is a theory which is expected (if developed) to produce a unification of GUT (the Grand Unified Theory of strong, weak and electro-magnetic forces) with gravity, via supersymmetry. In this approach, string theories arise as approximations of M-theory. In most applications related to M-theory, a $G_2$-manifold is deformed to a compact $G_2$-variety with isolated singularities. One local construction of conical
singularities of this type is based on Bryant-Salamon examples of complete $G_2$-manifolds (see [BS]). In this approach, the study of conical singularities is essentially reduced to the 4-dimensional geometry.

An explicit mathematical study of these singular examples and their connection to physics and theory of Einstein manifolds is found in [AW]. Also, Hitchin’s flow can be used to produce many such examples in a uniform way (see [GYZ])

1.3 Structure operator on manifolds with parallel differential form

Much study in Kähler geometry is based on the interplay between the de Rham differential and the twisted de Rham differential $d^c := -I \circ d \circ I$. We construct a similar operator $d_c$ for any manifold with a parallel differential form. This operator no longer satisfies $d_c^2 = 0$; however, it satisfies many properties expected from the twisted de Rham differential in Kähler geometry. Most importantly, a version of $dd^c$-lemma is true in this setting (Proposition 1.1).

Just as in the usual case, this may lead to results in rational homotopy theory (see Subsection 1.6 in the present introduction).

To simplify the exposition, we restrict ourselves presently to Riemannian manifolds $(M, \omega)$ with a parallel 3-form. These include Riemannian 3-manifolds, Calabi-Yau threefolds and $G_2$-manifolds. Just like it happens in 3-dimensional case, such a 3-form defines a skew-symmetric cross-product on $\Lambda^1(M)$:

$$x, y \mapsto \omega(x^\sharp, y^\sharp, \cdot)$$

($\cdot^{\sharp}$ denotes taking the dual with respect to the metric). Consider the operator on differential forms

$$\xi_{i_1} \wedge \xi_{i_2} \wedge \ldots \wedge \xi_{i_k} \mapsto \sum_{1 \leq a < b \leq k} (-1)^{a+b-1} \Psi(\xi_{i_a}, \xi_{i_b}) \wedge \xi_{i_1} \wedge \xi_{i_2} \wedge \ldots \wedge \xi_{i_a} \wedge \ldots \wedge \xi_{i_b} \wedge \ldots \wedge \xi_{i_k}$$

where $\xi_i$ is an orthonormal frame in $\Lambda^1(M)$. Denote by

$$C : \Lambda^i(M) \rightarrow \Lambda^{i+1}(M)$$

the dual operator (to identify $\Lambda^i(M)$ with its dual, we use the natural metric on $\Lambda^i(M)$ induced from the Riemannian structure on $M$). Then $C$ is called the structure operator on $(M, \omega)$. 

5
In Section [2] we give another definition of $C$, which works for an arbitrary parallel $i$-form $\omega$. It is not difficult to check that this definition is compatible to the one given above. When $(M, \omega)$ is Kähler, $C$ becomes the complex structure operator on $M$, and the identities we prove in general case become the usual Kähler identities.

Denote by $d_c$ the anticommutator $\{C, d\} = dC + Cd$. We show that $d_c$ commutes with $d$, $d^*$, and satisfies the following version of $dd_c$-lemma

**Proposition 1.1:** Consider a compact Riemannian manifold equipped with a parallel differential form. Let $\eta$ be a differential $k$-form satisfying $d\eta = d_c\eta = 0$. Assume, moreover, that $\eta$ is $d_c$-exact: $\eta = d_c\xi$. Then $\eta = dd_c\xi'$, for some differential form $\xi'$.

**Proof:** Follows immediately from Proposition 2.20 (see Remark 2.21).

**Remark 1.2:** The operator $d_c$ satisfies the Leibniz identity:

$$d_c(a \wedge b) = d_c(a) \wedge b + (-1)^{\tilde{a}\tilde{b}} a \wedge d_c(b),$$

where $\tilde{a}$, $\tilde{b}$ denotes parity of a form. However, $d^2_c \neq 0$. Also, the $dd_c$-lemma is less strong than the usual $dd^c$-lemma: given a $d$-exact, $d, d_c$-closed form $\eta$, we cannot show that $\eta = dd_c\xi'$ (though this could be true in the case of $G_2$-manifolds).

### 1.4 Donaldson-Thomas bundles

The twisted de Rham operator has many uses in $G_2$-geometry. In many ways, $d_c$ defines the same kind of structures as known in algebraic geometry from the study of the holomorphic structure operator $\overline{\partial} = \frac{d - \sqrt{-1} d^c}{2}$. Let $M$ be a $G_2$-manifold. The $G_2$-action gives a decomposition

$$\Lambda^2(M) = \Lambda^2_7(M) \oplus \Lambda^2_{14}(M)$$

onto a sum of irreducible representations of $G_2$.

**Definition 1.3:** [DT] Let $(B, \nabla)$ be a vector bundle with connection on a $G_2$-manifold $M$, and $\Theta \in \Lambda^2(M) \otimes \text{End}(B)$ its curvature. Then $(B, \nabla)$ is called a **Donaldson-Thomas bundle** if $\Theta$ lies inside $\Lambda^2_{14}(M) \otimes \text{End}(B)$. 
This is a natural generalization of the Hermitian-Einstein condition, known from algebraic geometry. In fact, when \( M \) is constructed from a Calabi-Yau threefold \( W \), \( M = W \times S^1 \), the Donaldson-Thomas bundles can be obtained as a pullback of Hermitian-Einstein bundles from \( W \) to \( M \). Also, the Donaldson-Thomas condition implies that the functional

\[
(B, \nabla) \mapsto \int_M ||\Theta||^2 \text{Vol}(M)
\]

has an absolute minimum at \( (B, \nabla) \). In other words, Donaldson-Thomas bundles are always instantons.

Geometry of Donaldson-Thomas bundles is much studied in connection with physics and algebraic geometry, see e.g. [L], [LL].

Given a Hermitian vector bundle \((B, \nabla)\) on a Kähler manifold, the holomorphic condition can be written as \( \Theta \in \Lambda^{1,1}(M) \otimes \text{End}(B) \). This equation can be rewritten as \( \{\nabla, \nabla^c\} = 0 \), where \( \nabla^c = -I \circ \nabla \circ I = [W_I, \nabla] \) (\( W_I \) denotes the Kähler-Weil operator, acting on \( \Lambda^{p,q}(M) \) as \( \sqrt{-1} (p - q) \)). In \( G_2 \)-geometry the role of \( W_I \) is played by the structure operator \( C \).

The Donaldson-Thomas bundles can be interpreted in terms of a structure operator, repeating the above description for holomorphic bundles verbatim.

**Proposition 1.4:** Let \( M \) be a \( G_2 \)-manifold, \( C : \Lambda^i(M) \longrightarrow \Lambda^{i+1}(M) \) the structure operator, and \((B, \nabla)\) a vector bundle with connection,

\[
\nabla : B \otimes \Lambda^i(M) \longrightarrow B \otimes \Lambda^{i+1}(M).
\]

Consider an operator \( \nabla^c := \{C, \nabla\} \),

\[
\nabla^c : B \otimes \Lambda^i(M) \longrightarrow B \otimes \Lambda^{i+2}(M).
\]

Then \((B, \nabla)\) is a Donaldson-Thomas bundle if and only if \( \nabla, \nabla^c \) commute.

**Proof:** Using graded Jacobi identity, we obtain

\[
[C, \nabla^2] = \frac{1}{2}[C, \{\nabla, \nabla\}] = [\nabla, [C, \nabla]] = [\nabla, \nabla^c].
\]

However, \( [C, \nabla^2] = C(\Theta) \), where \( \Theta \) is the curvature form. In Proposition 3.13 we show that \( \text{ker } C \big|_{\Lambda^2(M)} \) is exactly \( \Lambda^2_{14}(M) \), hence

\[
C(\Theta) = 0 \iff \Theta \in \Lambda^2_{14}(M) \otimes \text{End}(B).
\]
1.5 Localization functor and rational homotopy

The homotopy formality for Kähler manifold, observed by Deligne, Griffiths, Morgan, Sullivan ([DGMS]), is one of the deepest and most powerful results of Kähler geometry. Since [DGMS] appeared, there was a whole cornucopia of research dedicated to this theme. Formality was used to study the deformations and moduli spaces (see e.g. [GM], [BK], [V1]), in Mirror Symmetry and topology. The reason for all these equations lies in the so-called Master equation (also known as the Maurer-Cartan equation)

\[ d\gamma = -\frac{1}{2} [\gamma, \gamma]. \]

in a differential graded (DG-) Lie algebra, which is responsible for deformation theory for most objects in algebraic geometry. Solutions of this equation (up to a relevant equivalence) are homotopy invariants of the DG-Lie algebra ([BK]).

This equation can be solved recursively, if the relevant Massey products vanish (in fact, Massey products can be defined as obstructions to finding solutions of Maurer-Cartan equation - see e.g. [BT]). The homotopy formality implies vanishing of Massey products, providing a way to solve the Maurer-Cartan equation in various contexts.

In the proof of homotopy formality for Kähler manifolds ([DGMS]), the key argument hinges on $dd^c$-lemma; one should expect that the $G_2$-version of $dd^c$-lemma (Proposition 1.1) will give us information about rational homotopy of $G_2$-manifolds.

The topological utility of rational homotopy is based on the Quillen-Sullivan localization construction, [Q], [Su]. The Q-localization functor in homotopy category maps a simply connected cellular space $X$ to a space $X_Q = \text{Loc}_Q(X)$ with $H^i(X_Q, Z) \cong H^i(X, Z) \otimes \mathbb{Q}$ and $\pi_i(X_Q) \cong \pi_i(X) \otimes \mathbb{Q}$. The spaces which are homotopy equivalent to their localization are called Q-local. We have $\text{Loc}_Q(X) \cong \text{Loc}_Q(\text{Loc}_Q(X))$; in other words, all spaces of form $\text{Loc}_Q(X)$ are Q-local.

Given a cellular space, one could construct its de Rham complex, using piecewise smooth differential forms. This construction maps homotopy equivalent spaces to weakly equivalent differential graded (DG-) algebras (see Definition 2.22). We obtain a functor $DR: \text{Hot} \rightarrow \text{DG-Alg}$ of the corresponding categories. Moreover, this functor commutes with localization, and gives an equivalence of homotopy category of Q-local simply connected spaces and the category DG-Alg of DG-algebras. This reduces the study of rational homotopies (homotopies of Q-local spaces) to the study of DG-algebras.
The localization construction (which is defined in many other contexts, see [D]) is one of the key ideas of modern algebraic topology. Sullivan needed localization in order to prove the Adams’ conjecture, and Quillen used localization to give the definition of algebraic K-theory. Since then, many other uses of the same construction were found; including Voevodsky’s celebrated motivic homotopy theory.

Two DG-algebras are called quasi-isomorphic if there exists a quasi-isomorphism (morphism, inducing isomorphism on cohomology) from one to another. The equivalence relation generated by quasi-isomorphism is called weak equivalence of DG-algebras (Definition 2.22).

Rational homotopy is a study of DG-algebras, up to weak equivalence.

A DG-algebra \( (A^*,d) \) is called homotopy formal if it is weakly equivalent to its cohomology algebra \( (H^*(A),0) \). A simply connected topological space is called formal if its de Rham algebra is formal. The rational homotopies of formal spaces (in particular, all rational homotopy groups) are determined by the algebraic structure on cohomology.

Not all DG-algebras are formal; the best known obstruction to formality is called the Massey product (see e.g. [BT]). However, there are more obstructions to formality that just a Massey product. S. Halperin and J. Stasheff ([HS]) constructed explicitly a complete set of obstructions

\[
\{O_n, n = 1, 2, 3, \ldots\}
\]

to homotopy formality, \( O_n \) defined if all \( O_i, i < n \) vanish.

Since homotopy formality of Kähler manifolds was established, many people studied the influence of differential geometric structures on rational homotopy. Much of this work was focused on the study of rational homotopy of compact symplectic manifolds (there is a book [TO], dedicated especially to this subject). Using Deligne-Griffiths-Morgan-Sullivan formality theorem, one obtains all kinds of symplectic manifolds admitting no Kähler structures.

In physics, \( G_2 \)-manifolds appear as a generalization of Calabi-Yau threefolds; formality is expected.

### 1.6 Formality for \( G_2 \)-manifolds

Homotopy formality for \( G_2 \)-manifolds was studied by Gil Cavalcanti in his thesis (see [C]). The \( G_2 \)-structure gives certain constraints on the cohomology ring of a manifold: the multiplication by the standard 3-form \( \omega \) gives an isomorphism

\[
H^2(M) \xrightarrow{\wedge \omega} H^5(M).
\]
Rational homotopy and parallel forms

M. Verbitsky, February 23, 2005

and the 2-form
\[ \eta \mapsto \int_M \eta \wedge \eta \wedge \omega \]
on \( H^2(M, \mathbb{R}) \) must be positive definite. Also, \( H^1(M) = 0 \). Cavalcanti constructed examples of non-formal 7-manifolds satisfying these constraints. He also showed that for \( \dim H^2(M) \leq 2 \), these constraints indeed imply formality.

The \( G_2 \)-version of \( dd^c \)-lemma (Proposition 1.1) should give information about rational homotopy, in the same way that the usual \( dd^c \)-lemma leads to formality of Kähler manifolds. Indeed, \( (\ker d_c) \) is a subalgebra of \( \Lambda^*(M) \) which is weakly equivalent to the de Rham algebra of \( M \) (Proposition 2.11), and the quotient algebra

\[ \left( H^*_c(M), d \right) \cong \frac{\ker d_c}{(\ker d_c) \cap (\text{im } d_c)} \]
is also weakly equivalent to \( \Lambda^*(M) \). We call \( (H^*_c(M), d) \) the pseudo-cohomology of \( M \) (Definition 2.15). We don’t call it cohomology, because \( d^2_c \neq 0 \).

A form \( \eta \in \Lambda^*(M) \) is called pseudo-harmonic if \( \eta \in (\ker d_c) \cap (\ker^* d_c) \), where \( d^*_c \) is a Hermitian adjoint to \( d_c \). Just as happens for usual cohomology, the space of pseudo-harmonic forms \( \mathcal{H}^*_c(M) \) is isomorphic to pseudo-cohomology:

\[ \left( H^*_c(M), d \right) \cong \left( \mathcal{H}^*_c(M), d \right) \]

(Proposition 2.19). All harmonic forms are also pseudo-harmonic. We consider an orthogonal decomposition

\[ \mathcal{H}^*_c(M) \cong \mathcal{H}^*(M) \oplus \mathcal{H}^*_c(M)_{>0} , \]

where \( \mathcal{H}^*_c(M)_{>0} \) is the sum of all positive eigenspaces of the Laplacian acting on \( \mathcal{H}^*_c(M) \). From the arguments given above, we immediately obtain the following theorem.

**Theorem 1.5:** Let \( M \) be a compact \( G_2 \)-manifold, and \( \mathcal{H}^*_c(M)_{>0} \) the sum of all positive eigenspaces of the Laplacian acting on \( \mathcal{H}^*_c(M) \). Assume that \( \mathcal{H}^*_c(M)_{>0} = 0 \). Then \( M \) is formal.

**Proof:** This is Corollary 2.23.
We were unable to show that $H_\ast^c (M)_{>0} = 0$ for all $G_2$-manifolds. However, this space was computed fairly explicitly, in terms of $G_2$-action on differential forms.

**Proposition 1.6:** Let $M$ be a compact $G_2$-manifold, and $H_\ast^c (M)_{>0} = 0$ the vector space defined above. Then $H_\ast^c (M)_{>0} = 0$ unless $i = 3$ or 4. The space $H_\ast^c (M)_{>0}$ is generated (over $\mathbb{C}$) by the solutions of the following equation

$$d\alpha = \mu \ast \alpha, \quad \alpha \in \Lambda^3_{27} (M),$$

(1.1)

where $\mu \in \mathbb{C}$ is a non-zero number, and $\Lambda^3_{27} (M)$ is the 27-dimensional irreducible component of $\Lambda^3 (M)$ under the $G_2$-action (see (3.2)). Similarly, $H_\ast^c (M)_{>0}$ is generated by the solutions of equation $d\ast \eta = \mu \eta$, $\eta \in \Lambda^3_{27} (M)$.

**Proof:** See Theorem 4.2.

The formula (1.1) is suggestive of equations found in Hitchin’s paper on hamiltonian flow, [Hi2]. One may hope that a careful study of Hitchin’s flow in conjunction with (1.1) leads to some constraints on $H_\ast^c (M)_{>0}$, and, possibly, its vanishing, which leads to formality of $M$. However, even now Proposition 1.6 gives us some information about rational homotopy.

**Corollary 1.7:** Let $M$ be a compact $G_2$-manifold, and $(H_\ast^c (M), d)$ its pseudocohomology DG-algebra. Then $(H_\ast^c (M), d)$ is weakly equivalent to the de Rham algebra of $M$, and, moreover, $d\big|_{H_\ast^c (M)} = 0$ unless $i = 3$.

This result can be used to study the obstructions $O_i$ to formality of $(H_\ast^c (M), d)$, defined in [HS] (see Subsection 1.5). It turns out that only the first obstruction $O_1$ is relevant for rational homotopy, and if it vanishes, $O_i$, $i > 0$ also vanish, and the DG-algebra $(H_\ast^c (M), d)$ and $(\Lambda^\ast (M), d)$ is formal. However, the same result can be obtained from Gil Cavalcanti’s work, for all simply connected 7-manifolds.

In 1970-is, T. J. Miller showed that all simply connected orientable compact manifolds of dimensions up to 6 are formal ([M]). Moreover, Miller has shown that all $(k-1)$-connected orientable compact manifolds of dimension up to $2k + 2$ are formal. His arguments were simplified and generalized by M. Fernandez and V. Munoz ([FM]), who defined a notion of $k$-formal manifold, and shown that any orientable $k$-formal compact manifold of dimension up to $2k + 2$ is formal. They applied this theorem to obtain results about formality of compact symplectic manifolds.

11
G. Cavalcanti ([C]) studied 7-manifolds using the same conceptual framework, obtaining essentially (but in completely different terms) that obstructions to 3-formality for simply connected 7-manifolds can be reduced to vanishing of the first obstruction of Halperin-Stasheff.

It is unclear whether additional topological information might be gleaned from Corollary 1.7. It may possibly happen that for any 7-manifold (compact and oriented) its de Rham algebra is weakly equivalent to an algebra with non-degenerate Poincare pairing and a differential which vanishes in all dimensions except \( i = 3 \). In this case we don’t obtain much topological information from Corollary 1.7.

2 Riemannian manifolds with a parallel differential form

2.1 Structure operator and twisted differential

Let \( M \) be a \( C^\infty \)-manifold. We denote the smooth forms on \( M \) by \( \Lambda^*(M) \). Given an odd or even form \( \alpha \in \Lambda^*(M) \), we denote by \( \tilde{\alpha} \) its parity, which is equal to 0 for even forms, and 1 for odd forms. An operator \( f \in \text{End}(\Lambda^*(M)) \) preserving parity is called even, and one exchanging odd and even forms is odd; \( \tilde{f} \) is equal 0 for even forms and 1 for odd.

Given a \( C^\infty \)-linear map \( \Lambda^1(M) \xrightarrow{p} \Lambda^{\text{odd}}(M) \) or \( \Lambda^1(M) \xrightarrow{p} \Lambda^{\text{even}}(M) \), \( p \) can be uniquely extended to a \( C^\infty \)-linear derivation \( \rho \) on \( \Lambda^*(M) \), using the rule

\[
\rho|_{\Lambda^1(M)} = p, \quad \rho|_{\Lambda^0(M)} = 0, \quad \rho(\alpha \wedge \beta) = \rho(\alpha) \wedge \beta + (-1)^{\tilde{\rho} \tilde{\alpha}} \alpha \wedge \rho(\beta).
\]

Then, \( \rho \) is an even (odd) differentiation of the graded commutative algebra \( \Lambda^*(M) \).

Definition 2.1: Let \( M \) be a Riemannian manifold, and \( \omega \in \Lambda^k(M) \) a differential form. Consider an operator \( C : \Lambda^1(M) \rightarrow \Lambda^{k-1}(M) \) mapping \( \nu \in \Lambda^1(M) \) to \( \omega \wedge \nu^\sharp \), where \( \nu^\sharp \) is the vector field dual to \( \nu \). Alternatively, \( C(\nu) \) can be written as \( C(\nu) = *(*\omega \wedge \nu) \). The corresponding differentiation

\[
C : \Lambda^*(M) \rightarrow \Lambda^{*+k-2}(M)
\]

is called the structure operator of \((M, \omega)\). Parity of \( C \) is equal to that of \( \omega \).
Remark 2.2: When \((M, I, g)\) is a Kähler manifold and \(\omega\) is its Kähler form, \(\mathcal{C}(\nu) = I(\nu)\), and \(C\) is the standard Kähler-Weil operator, acting on \((p, q)\)-forms as a multiplication by \((p - q)\sqrt{-1}\).

Definition 2.3: Let \(M\) be a Riemannian manifold, \(\omega \in \Lambda^k(M)\) a differential form, which is parallel with respect to the Levi-Civita connection. Denote by \(d_c\) the supercommutator

\[
\{d, C\} := dC - (-1)^{\frac{\partial}{\sqrt{-1}}}Cd
\]

This operator is called the **twisted de Rham operator of** \((M, \omega)\). Being a graded commutator of two graded differentiations, \(d_c\) is also a graded differentiation of \(\Lambda^*(M)\).

Remark 2.4: When \((M, I, g)\) is a Kähler manifold and \(\omega\) is its Kähler form, \(d_c\) is equal to the well-known twisted differential

\[
d_c = \partial - \partial \sqrt{-1}.
\]

Of course, for a general form \(\omega\), \(d_c^2\) can be non-zero.

Proposition 2.5: Let \((M, \omega)\) be a Riemannian manifold equipped with a parallel form \(\omega\), and \(L_\omega\) the operator \(\eta \mapsto \eta \wedge \omega\). Then

\[
d_c = \{L_\omega, d^*\},
\]

where \(\{\cdot, \cdot\}\) denotes the supercommutator,

\[
\{L_\omega, d^*\} = L_\omega d^* - (-1)^{\frac{\partial}{\sqrt{-1}}}d^* L_\omega,
\]

and \(d^* = -*d^*\) is the adjoint to \(d\).

**Proof:** Denote by \(\nabla\) the Levi-Civita connection,

\[
\nabla : \Lambda^*(M) \rightarrow \Lambda^*(M) \otimes \Lambda^1(M).
\]

Let \(\eta \in \Lambda^i(M)\). Clearly, \(d^* \eta\) is obtained from \(\nabla \eta \in \Lambda^i(M) \otimes \Lambda^1(M)\) by applying the isomorphism

\[
\Lambda^i(M) \otimes \Lambda^1(M) \cong \Lambda^i(M) \otimes TM
\]

induced by the Riemannian structure and then plugging the \(TM\)-part into \(\Lambda^i(M)\):

\[
d^* \eta = \mathcal{J}(\nabla \eta).
\]

(2.1)
Since $\nabla \omega = 0$, $\{L_\omega, d^*\}$ is equal to the composition

\[
\Lambda^i(M) \xrightarrow{\nabla} \Lambda^i(M) \otimes \Lambda^1(M) \\
\xrightarrow{C \otimes \text{Id} \circ \wedge \circ C} \Lambda^{i+k-2}(M) \otimes \Lambda^1(M) \xrightarrow{\wedge} \Lambda^{i+k-1}(M)
\]

(the last arrow is exterior multiplication). Indeed, $L_\omega$ commutes with $\nabla$, and therefore, by (2.1), $\{L_\omega, d^*\}$ is written as a composition of $\nabla$ and a commutator of $C^\infty$-linear maps $L_\omega$ and $\cdot$, where

\[
\cdot : \Lambda^{i+k}(M) \otimes \Lambda^1(M) \rightarrow \Lambda^{i+k-1}(M)
\]

maps $\eta \otimes \nu$ to $\eta \cdot \nu^i$. However, by definition,

\[
\{L_\omega, \cdot\}(\eta \otimes \nu) = C(\eta) \wedge \nu.
\]

This gives

\[
\{L_\omega, d^*\}(\eta) = [L_\omega, \cdot](\nabla \eta).
\]  \hspace{1cm} (2.2)

Similarly, $[\nabla, C] = 0$, hence $d_c$ is written as a composition of $\nabla$ and a $C^\infty$-linear map

\[
C \otimes \text{Id} \circ \wedge \circ C : \Lambda^i(M) \otimes \Lambda^1(M) \rightarrow \Lambda^{i+k-1}(M),
\]  \hspace{1cm} (2.3)

where $\wedge : \Lambda^*(M) \Lambda^1(M) \rightarrow \Lambda^{*+1}(M)$ denotes the exterior product. Since $C$ is a differentiation, the operator (2.3) is equal to

\[
\text{Id} \otimes C \circ \wedge : \Lambda^i(M) \otimes \Lambda^1(M) \rightarrow \Lambda^{i+k-1}(M).
\]

This gives

\[
\{d, C\}(\eta) = \text{Id} \otimes C \circ \wedge(\nabla \eta).
\]  \hspace{1cm} (2.4)

However, by definition of $C$, we have $[L_\omega, \cdot](\eta \otimes \nu) = \eta \wedge C(\nu)$, hence the right hand sides of (2.4) and (2.2) are equal. This proves Proposition 2.5.

**Remark 2.6:** In the Kähler case, Proposition 2.5 becomes the following well-known Kähler identity: $[L_\omega, d^*] = d^C$.

### 2.2 Generalized Kähler identities and twisted Laplacian

**Proposition 2.7:** Let $M$ be a Riemannian manifold equipped with a parallel differential $k$-form $\omega$, $d_c$ the twisted de Rham operator constructed above, and $d^*_c$ its Hermitian adjoint. Then
(i) The following supercommutators vanish:
\[ \{d, d_c\} = 0, \quad \{d, d_c^*\} = 0, \quad \{d^*, d_c\} = 0, \quad \{d^*, d_c^*\} = 0, \]

(ii) The Laplacian \( \Delta = \{d, d^*\} \) commutes with \( L_\omega : \eta \rightarrow \omega \wedge \eta \) and its Hermitian adjoint operator, denoted as \( \Lambda_\omega : \Lambda^i(M) \rightarrow \Lambda^{i-k}(M) \).

(iii) Denote the supercommutator of \( d_c, d_c^* \) by \( \Delta_c \). By definition, \( \Delta_c = d_c d_c^* + d_c^* d_c \) when \( k \) is even, and \( \Delta_c = d_c d_c^* - d_c^* d_c \) when \( k \) is odd. Then
\[ \Delta_c = (-1)^\tilde{\omega} \{d^*, [H_\omega, d]\}, \]
where \( H_\omega = \{L_\omega, \Lambda_\omega\} \).

**Proof:** We use the following basic lemma

**Basic Lemma:** Let \( \delta \) be an odd element in a graded Lie superalgebra \( A \) satisfying \( \{\delta, \delta\} = 0 \). Then \( \{\delta, \{\delta, x\}\} = 0 \) for all \( x \in A \), assuming that the base field is not of characteristic 2.

**Proof:** Using the graded Jacobi identity, we obtain
\[ \{\delta, \{\delta, x\}\} = -\{\delta, \{\delta, x\}\} + \{\{\delta, \delta\}, x\}. \]
This gives \( 2\{\delta, \{\delta, x\}\} = 0. \]

Now, \( \{d, d_c\} = \{d, \{d, C\}\} = 0 \) (by the Basic Lemma), and \( \{d^*, d_c\} = \{d^*, \{d^*, L_\omega\}\} = 0 \) (by Basic Lemma and Proposition 2.5). Taking Hermitian adjoints of these identities, we obtain the other two equations of Proposition 2.7 (i). Proposition 2.7 (i) is proven.

Now, the graded Jacobi identity implies
\[ [L_\omega, \Delta] = \{L_\omega, \{d, d^*\}\} = (-1)^\tilde{\omega} \{d, \{L_\omega, d^*\}\}. \tag{2.5} \]
We proved Proposition 2.7 (i). Proposition 2.7 (i) is proven.

Finally, Proposition 2.7 (iii) is proven as follows:
\[ \{\{L_\omega, d^*\}, \Lambda_\omega, d\} = \{\{L_\omega, \{d^*, d_c^*\}\} + (-1)^\tilde{\omega} \{d^*, \{L_\omega, \Lambda_\omega, d\}\} \tag{2.6} \]
by graded Jacobi identity. Also,
\[ \{ L_\omega, \{ \Lambda_\omega, d \} \} = \{ H_\omega, d \} + (-1)^{\bar{\omega}} \{ \Lambda_\omega, \{ L_\omega, d \} \}. \tag{2.7} \]

However, \( \{ L_\omega, d \} = 0 \) as \( \omega \) is closed. Comparing (2.7) and (2.6), we obtain
\[ \Delta_c = (-1)^{\bar{\omega}} \{ d^* , \{ H_\omega, d \} \}. \]

We proved Proposition 2.7 (iii). \( \blacksquare \)

**Remark 2.8:** When \( (M, \omega) \) is a Kähler manifold, Proposition 2.7 (i) gives the standard commutation relations between \( d, d^c, (d^c)^*, \) Proposition 2.7 (ii) is well known, and Proposition 2.7 (iii) gives
\[ \{ d^c, (d^c)^* \} = \Delta_c = \{ d^*, [H, d] \} = \Delta, \]
because \([H, d] = d\) as Lefschetz theorem implies.

**Corollary 2.9:** Let \( (M, \omega) \) be a Riemannian manifold equipped with a parallel differential form, and \( \eta \) a harmonic form on \( M \). Then \( \omega \wedge \eta \) is harmonic.

**Proof:** Follows from Proposition 2.7 (ii). \( \blacksquare \)

This statement seems to be well known.

Further on, we shall need the following trivial lemma.

**Lemma 2.10:** Let \( (M, \omega) \) be a compact Riemannian manifold equipped with a parallel differential form, and \( \eta \) a harmonic form on \( M \). Consider the twisted de Rham operator \( d_c \) constructed above. Then \( d_c(\eta) = 0 \).

**Proof:** Since \( M \) is compact, \( d^* \eta = 0 \). Then \( d_c \eta = d^* L_\omega \eta \). On the other hand, \( L_\omega \eta \) is harmonic, by Corollary 2.9, hence satisfies \( d^* L_\omega \eta = 0 \). \( \blacksquare \)

### 2.3 The differential graded algebra \( (\ker d_c, d) \)

Let \( (M, \omega) \) be a Riemannian manifold equipped with a parallel form, and \( d_c \) the twisted de Rham operator constructed above. By construction, \( d_c \) is a differentiation of \( \Lambda^*(M) \). Therefore, \( \ker d_c \subset \Lambda^*(M) \) is a subalgebra. Since \( d \) and \( d_c \) supercommute, \( d \) acts on \( \ker d_c \). We consider \( (\ker d_c, d) \) as a differential graded algebra (a DG-algebra).
Recall that a homomorphism of DG-algebras is called a **quasi-isomorphism** if it induces isomorphism on cohomology.

**Proposition 2.11:** Let $(M, \omega)$ be a compact Riemannian manifold equipped with a parallel form. Consider the natural embedding

$$(\ker d_c, d) \hookrightarrow (\Lambda^*(M), d).$$  \hspace{1cm} (2.8)

Then this map is a quasi-isomorphism.

**Proof:** Let $\Lambda^*(M)_\alpha$ be the eigenspace of $\Delta$, corresponding to the eigenvalue $\alpha$. Since $\Delta$ is a self-adjoint operator with discrete spectrum, we have a decomposition $\Lambda^*(M) \cong \bigoplus_\alpha \Lambda^*(M)_\alpha$. Consider the subcomplex

$$\ldots \xrightarrow{d} \Lambda^*(M)_\alpha \xrightarrow{d} \Lambda^{*+1}(M)_\alpha \xrightarrow{d} \ldots$$  \hspace{1cm} (2.9)

corresponding to an eigenvalue $\alpha$. Clearly, for $\alpha \neq 0$, the complex \ref{2.9} is exact. Let

$$\ldots \xrightarrow{d} (\ker d_c)_\alpha \xrightarrow{d} (\ker d_c)_\alpha \xrightarrow{d} \ldots$$  \hspace{1cm} (2.10)

be the action of $d$ on the $\alpha$-eigenspace of $\Delta$ on $(\ker d_c)$ ($\Delta$ commutes with $d_c$ as Proposition 2.7 implies).

For $\alpha = 0$, $(\ker d_c)_\alpha = \Lambda^*(M)_\alpha = H^*(M)$ as Lemma 2.10 implies. To prove Proposition 2.11 we need only to show that (2.10) has zero cohomology for $\alpha > 0$. However, for any closed form $\eta \in (\ker d_c)_\alpha$, we have

$$\eta = \frac{1}{\alpha} (dd^* + d^*d)\eta = \frac{1}{\alpha} dd^*\eta$$

and $d^*\eta$ lies inside $(\ker d_c)_\alpha$ as $d_c$ and $d^*$ commute [Proposition 2.7]. Therefore, $\eta$ is exact. This proves Proposition 2.11. \blacksquare

The following claim is clear, as $\Delta_c$ and $\Delta$ commute, and $\{d_c, d^*_c\}^* = \{d^*_c, d_c\} = (-1)^{1-d_c}\{d_c, d^*_c\}$.

**Claim 2.12:** Let $(M, \omega)$ be a compact Riemannian manifold equipped with a parallel form, and $\Delta_c = \{d_c, d^*_c\}$ the operator constructed above. Let $\Lambda^*(M)_\alpha$ be the eigenspace of the Laplacian of eigenvalue $\alpha$. Then $\Delta_c$ preserves $\Lambda^*(M)_\alpha$ and acts on $\Lambda^*(M)_\alpha$ as a self-adjoint or anti-self-adjoint operator. In particular, $\Delta_c$ is diagonalizable, on some dense subspace of $\Lambda^*(M) \otimes \mathbb{R} \mathbb{C}$.\hfill 17
Remark 2.13: Notice that $\Delta_c$ is not a priori elliptic, hence it has no spectral decomposition. However, it preserves the finite-dimensional eigenspaces of the Laplacian, and is diagonalizable on these eigenspaces.

2.4 Pseudocohomology of the operator $d_c$

Lemma 2.14: Let $(M,\omega)$ be a compact Riemannian manifold equipped with a parallel form, and $(\ker d_c, d)$ the differential graded algebra constructed above. Consider the subspace

$$V = (\ker d_c) \cap d_c(\Lambda^*(M)) \subset (\ker d_c). \quad (2.11)$$

Then $V$ is a differential ideal in the differential graded algebra $(\ker d_c, d)$. In other words, $\ker d_c \cdot V \subset V$ and $dV \subset V$.

Proof: Given $x \in \ker d_c$, $y \in V$, $y = d_c z$, we write

$$d_c(x \wedge z) = (-1)^{d_c x} x \wedge d_c z.$$ Therefore, $V$ is an ideal. To prove that $dV \subset V$, we write $v \in V$ as $d_c(w)$, then $dv = (-1)^{d_c w} d_c dw$. ■

Definition 2.15: The quotient $\frac{(\ker d_c)}{(\ker d_c) \cap (\im d_c)}$ is called the pseudocohomology of $d_c$. As Lemma 2.14 implies, pseudocohomology is a differential graded algebra. We denote it by $(H_c^*(M), d)$.

Remark 2.16: We don’t call $H_c^*(M)$ cohomology of $d_c$, because $d_c^2$ is not necessarily zero. In the literature, the pseudocohomology of an operator is known under the name twisted cohomology (see e.g. in [Va]).

Definition 2.17: Let $\eta \in \Lambda^*(M)$ be a form which satisfies $d_c \eta = d_c^* \eta = 0$. Then $\eta$ is called pseudo-harmonic. The space of all pseudo-harmonic forms is denoted by $\mathcal{H}_c^*(M)$. By Proposition 2.7 (i), the de Rham differential preserves $\mathcal{H}_c^*(M)$.

Remark 2.18: From Lemma 2.10 it follows immediately that all harmonic forms are pseudo-harmonic: $\mathcal{H}^*(M) \subset \mathcal{H}_c^*(M)$. 

Proposition 2.19: Let \((M, \omega)\) be a compact Riemannian manifold equipped with a parallel form, and

\[
\mathcal{H}_c^*(M) \xrightarrow{i} H_c^*(M)
\]

the natural projection map. Then \(i\) is an isomorphism, compatible with the de Rham differential.

Proof: We represent \(\Lambda^*(M)\) as a (completion of) a direct sum of eigenvalues of the Laplacian. Using \(d_c, d_c^*\)-invariance of these eigenspaces, we may work with the associated decompositions within these eigenspaces. Abusing the language, we approach \(\Lambda^*(M)\) as if it were finite-dimensional, but in fact we work with these eigenspaces, which are finite-dimensional.

From

\[
(\Delta_c \alpha, \alpha) = (d_c \alpha, d_c \alpha) + (d_c^* \alpha, d_c^* \alpha)
\]

we obtain that \(\ker \Delta_c = \ker d_c \cap \ker d_c^*\). From \((d_c \alpha, \beta) = (\alpha, d_c^* \beta)\), we find that \(\ker d_c = (\text{im } d_c^*)^\perp\), \(\ker d_c^* = (\text{im } d_c)^\perp\), where \((\cdots)^\perp\) denotes the orthogonal complement. Therefore,

\[
\ker \Delta_c = (\text{im } d_c)^\perp \cap (\text{im } d_c^*)^\perp = (\text{im } d_c + \text{im } d_c^*)^\perp.
\]

Given \(\alpha \in \Lambda^*(M)\), let \(\Pi \alpha\) denote the orthogonal projection of \(\alpha\) to \(\ker \Delta_c\). Then \(\alpha - \Pi \alpha\) is orthogonal to \(\ker \Delta_c\), hence

\[
\alpha - \Pi \alpha \in \left(\text{im } d_c + \text{im } d_c^*\right).
\]

(2.13)

Now assume that \(\alpha \in \ker d_c\). The form \(\Pi(\alpha)\) also lies in \(\ker d_c\), because \(\ker \Delta_c \subset \ker d_c\). Therefore, \(\alpha - \Pi \alpha\) lies in \(\ker d_c\), hence, is orthogonal to \(\text{im } d_c^*\). Using (2.13), we obtain that \(\alpha - \Pi \alpha \in \text{im } d_c\).

Therefore,

\[
\ker d_c = (\ker d_c) \cap (\text{im } d_c) \oplus \mathcal{H}_c^*(M).
\]

(2.14)

From (2.14) Proposition 2.19 follows directly. 

Proposition 2.20: Let \((M, \omega)\) be a compact Riemannian manifold equipped with a parallel form, and

\[
(\ker d_c, d) \xrightarrow{\pi} (H_c^*(M), d)
\]

the homomorphism of differential graded algebras constructed above. Then \(\pi\) is a quasi-isomorphism.

19
Proof: By definition, (2.13) is surjective. To show that it is a quasi-isomorphism, we need to prove that any $d$-closed $\eta \in \ker \pi$ is $d$-exact. However, $\ker \pi \subset (\ker d_c) \cap (\im d_c)$, and by (2.14) this space is orthogonal to $H^*(M)$. Using Remark 2.18 we obtain that any $\eta \in \ker \pi$ is orthogonal to the space of harmonic forms. Using the spectral decomposition, we obtain that $\eta = \sum \eta_{\alpha_i}$, where $\Delta \eta_{\alpha_i} = \alpha_i \eta_{\alpha_i}$, and $\{\alpha_i\}$ are positive real numbers. Since $\Delta$ commutes with $d_c$ and $d^*_c$, the components $\eta_{\alpha_i}$ also belong to $\ker \pi$. This gives $\eta_{\alpha_i} = \frac{1}{\alpha_i} dd^*_c \eta_{\alpha_i}$, hence all the components $\eta_{\alpha_i}$ are $d$-exact. We obtain that $\eta$ is $d$-exact. Proposition 2.20 is proven.

Remark 2.21: The standard (and completely formal) argument is used to produce the $dd^*_c$-lemma from Proposition 2.20. Let $\eta$ be a $d_c$-exact, $d$-, $d^*_c$-closed form on $M$. We need to show that $\eta = dd^*_c \xi$. By definition, $\eta$ represents $0$ in $H^c(M)$. Since $(\ker d_c, d)$ is quasi-isomorphic to $(H^c(M), d)$, $\eta$ represents zero in the cohomology of $(\ker d_c, d)$. Therefore, $\eta = d\nu$, for some $\nu \in \ker d_c$. Now, the class $[\nu]$ of $\nu$ in $H^c(M)$ satisfies $d[\nu] = 0$. Using Proposition 2.20 again, we find that $[\nu] - [\nu'] = 0$, for some $d$-closed form $\nu' \in \ker d_c$. Therefore, $\nu - \nu' = d_c \xi$. Since $dd^*_c\xi = 0$, this gives $dd^*_c\xi = d\nu = \eta$.

Definition 2.22: Let $(A^*, d)$, $(B^*, d)$ be graded commutative differential graded algebras (DG-algebras, for short). If $(A^*, d)$ and $(B^*, d)$ can be connected by a sequence of quasi-isomorphisms

$$(A^*, d) \rightarrow (A^*_1, d_1), \quad (A^*_2, d_2) \rightarrow (A^*_1, d), \quad \ldots \quad (A^*_n, d_n) \rightarrow (B^*, d),$$

the DG $(A^*, d)$ and $(B^*, d)$ are called weak equivalent. A DG-algebra is called formal if it is weak equivalent to a DG-algebra with $d = 0$.

Corollary 2.23: Let $(M, \omega)$ be a compact Riemannian manifold equipped with a parallel form, and $(H^c(M), d)$ its pseudohoco-homology DG-algebra. Then $(\Lambda^*(M), d)$ is weak equivalent to $(H^c(M), d)$. Moreover, if every pseudoharmonic form is harmonic, then $(\Lambda^*(M), d)$ is formal.

Proof: By Proposition 2.11 the DG-algebra $(\Lambda^*(M), d)$ is quasi-isomorphic to $(\ker d_c, d)$. By Proposition 2.20 the DG-algebra $(\ker d_c, d)$ is quasi-isomorphic to $(H^c(M), d)$. Finally, if all pseudoharmonic forms are harmonic, the differential $d$ vanishes on $H^c(M)$, and Proposition 2.19 implies that $d = 0$ on $(H^c(M), d)$. ■

Remark 2.24: When $(M, \omega)$ is a compact Kähler manifold, $\Delta = \Delta_c$ as
the Kähler identities imply. In this situation, pseudoharmonic forms are the same as harmonic. This implies the celebrated result of [DGMS]: for any compact Kähler manifold, its de Rham DG-algebra is formal.

3 Structure operator for holonomy $G_2$-manifolds

3.1 $G_2$-manifolds

We base our exposition on [Hi].

Claim 3.1: Consider the natural action of $GL(7, \mathbb{R})$ on the space $\Lambda^3(V^*)$ of 3-forms on $V$, where $V = \mathbb{R}^7$. Then $GL(7, \mathbb{R})$ acts on $\Lambda^3(V^*)$ with two open orbits.

Proof: Well known (see e.g. [Sa]).

Definition 3.2: A 3-form $\omega$ on $V = \mathbb{R}^7$ is called non-degenerate if it lies in an open orbit.

The group $GL(7, \mathbb{R})$ is 49-dimensional, and dimension of $\Lambda^3(V^*)$ is 35. Therefore, a stabilizer of a non-degenerate 3-form has dimension 14. This stabilizer is a Lie group, of dimension 14, called $G_2$. For one orbit it is a compact form of $G_2$, for another orbit a non-compact real form. We call a non-degenerate 3-form $\omega$ on $V = \mathbb{R}^7$ positive if its stabilizer is a compact form of $G_2$.

Given a 3-form $\omega \in \Lambda^3(V^*)$, consider an $\Lambda^7(V^*)$-valued scalar product $V \times V \to \Lambda^7(V^*)$,

$$x, y \mapsto \frac{1}{6} (\omega \lrcorner x) \wedge (\omega \lrcorner y) \wedge \omega.$$

It is easy to check that $\tilde{g}$ is non-degenerate when $\omega$ is non-degenerate, and sign-definite when $\omega$ is positive. Consider $\tilde{g}$ as a section of $V^* \otimes V^* \otimes \Lambda^7(V^*)$, and denote by $K$ its determinant, $K \in \Lambda^7(V^*)^0$. Since 9 is odd, $K$ gives an orientation on $V$. Let $k := \sqrt[9]{K}$ be the corresponding section of $\Lambda^7(V^*)$, and $g := k^{-1} \tilde{g}$ the $\mathbb{R}$-valued bilinear symmetric form associated with $\tilde{g}$. Assume that $\omega$ is positive. A direct calculation implies that $g$ is positive definite, and in some orthonormal basis $e_1, ..., e_7 \in V^*$, $\omega$ is written as

$$\omega = (e_1 \wedge e_2 + e_3 \wedge e_4) \wedge e_5 + (e_1 \wedge e_3 - e_2 \wedge e_4) \wedge e_6 + (e_1 \wedge e_4 - e_2 \wedge e_3) \wedge e_7 + e_5 \wedge e_6 \wedge e_7. \quad (3.1)$$
**Definition 3.3:** Let $M$ be a 7-dimensional smooth manifold, and $\omega \in \Lambda^3(M)$ a 3-form. $(M, \omega)$ is called a **$G_2$-manifold** if $\omega$ is non-degenerate and positive everywhere on $M$. We consider $M$ as a Riemannian manifold, with the Riemannian structure determined by $\omega$ as above. The manifold $(M, g, \omega)$ is called a **holonomy $G_2$-manifold** if $\omega$ is parallel with respect to the Levi-Civita connection associated with $g$. Further on, we shall consider only holonomy $G_2$ manifolds, and (abusing the language) omit the word “holonomy”.

**Remark 3.4:** Holonomy $G_2$-manifolds have long and distinguished history. They appear in M. Berger’s list of irreducible holonomies ([Ber]). Local examples of holonomy $G_2$-manifolds were unknown until R. Bryant’s work of mid-1980-ies ([Br1]). Then R. Bryant and S. Salamon constructed a complete examples of holonomy $G_2$-manifoldy ([BS]), and D. Joyce ([J1]) constructed and studied compact holonomy $G_2$-manifolds at great length. For details of D. Joyce’s construction, see [J2]. Since then, the $G_2$-manifolds become crucially important in many areas of string physics, especially in M-theory.

Under the $G_2$-action, the space $\Lambda^*(M)$ splits into irreducible representations, as follows.

\[
\Lambda^2(M) \cong \Lambda^2_7(M) \oplus \Lambda^2_{14}(M), \\
\Lambda^3(M) \cong \Lambda^1_1(M) \oplus \Lambda^3_7(M) \oplus \Lambda^3_{27}(M)
\]  

(3.2)

where $\Lambda^j_i(M)$ is an irreducible $G_2$-representation of dimension $j$. Clearly, $\Lambda^*(M) \cong \Lambda^{7-*}(M)$ as a $G_2$-representation, and the spaces $\Lambda^4(M), \Lambda^5(M)$ split in a similar fashion. The spaces $\Lambda^0, \Lambda^1$ are irreducible.

The spaces $\Lambda^j_i(M)$ are defined explicitly, in a following way. $\Lambda^2_7(M)$ is $\Lambda_{s\omega}(\Lambda^6(M))$, where $\Lambda_{s\omega}$ is the Hermitian adjoint to $L_{s\omega}(\eta) = *\omega \wedge \eta$ (see Section 2). The space $\Lambda^2_{14}(M)$ is identified with $\mathfrak{g}_2 \subset \mathfrak{so}(TM)$ under the standard identification $\Lambda^2(\mathbb{C}) = \mathfrak{so}(TM)$. The space $\Lambda^3_7(M)$ is generated by $\omega$, $\Lambda^3_7(M)$ is equal to $\Lambda_{\omega}(\Lambda^6(M))$, where $\Lambda_{\omega}$ is the Hermitian adjoint of $L_{\omega}(\eta) = \omega \wedge \eta$ (see Section 2). Finally, $\Lambda^3_{27}(M)$ is identified with $(\ker L_{\omega}) \cap (\ker \Lambda_{\omega}) \subset \Lambda^3(M)$.

**Remark 3.5:** Notice that the operators $C, L_{\omega}, \Lambda_{\omega}$ from Section 2 are clearly $G_2$-invariant.
From the construction, it is clear that the splitting (3.2) can be obtained via the operators $L_\omega$, $\Lambda_\omega$, $L_{\ast\omega}$, $\Lambda_{\ast\omega}$. By Proposition 2.7 these operators commute with the Laplacian. Therefore, harmonic forms also split:

$$H^2(M) \cong H^2_7(M) \oplus H^2_{14}(M),$$

$$H^3(M) \cong H^3_1(M) \oplus H^3_7(M) \oplus H^3_{27}(M)$$

and similar splitting occurs on $H^4(M)$ and $H^5(M)$.

The following result is well known and is implied by a Bochner-Lichnerowicz-type argument using Ricci-flatness of holonomy $G_2$-manifolds.

**Claim 3.6:** Let $M$ be a compact $G_2$-manifold, and $\eta \in H^i_7(M)$ a harmonic form. Then $\eta$ is parallel. Moreover, if $H^1(M) = 0$, then $H^i_7(M) = 0$ ($i = 1, 2, 3, 4, 5, 6$).

**Proof:** See [J2]. □

**Remark 3.7:** A $G_2$-manifold is Ricci-flat, as shown by E. Bonan ([Bo]). Then $\pi_1(M)$ is finite, unless $M$ has a finite covering which is isometric to $T \times M'$, where $M'$ is a manifold with special holonomy, and $T$ a torus. When $\pi_1(M)$ is finite, $H^i_7(M) = 0$ as Claim 3.6 implies.

We shall also need the following linear-algebraic result, which is well known. Let $M$ be a $G_2$-manifold, and

$$\Lambda^2(M) \cong \Lambda^2_7(M) \oplus \Lambda^2_{14}(M)$$

the decomposition defined above. Consider the operator

$$\ast \circ L_\omega : \Lambda^2(M) \longrightarrow \Lambda^2(M).$$

This operator is $G_2$-invariant, hence by Schur’s lemma acts on $\Lambda^2_7(M)$ and $\Lambda^2_{14}(M)$ as scalars. These scalars are computed as follows

**Claim 3.8:** For any $\alpha \in \Lambda^2_7(M)$, we have $\ast L_\omega \alpha = 2\alpha$. For $\alpha \in \Lambda^2_{14}(M)$, we have $\ast L_\omega \alpha = -\alpha$.

**Proof:** See e.g. [Br2], (2.32). □

### 3.2 Structure operator for $G_2$-manifolds

Let $(M, \omega)$ be a $G_2$-manifold. We have two parallel forms on $M$: $\omega$ and $\ast\omega$, and the results of Section 2 can be applied to $\omega$ and $\ast\omega$ as well.
We denote by $C$, $C_{\omega}$ the corresponding structure operators, and by $d_c$ the operator $\{C, d\}$.

This part of the paper is a pure linear algebra. We never use the holonomy property: throughout this subsection, there is no need to assume that our $G_2$-manifold has holonomy in $G_2$.

Consider the operator $C^2 = \frac{1}{2}\{C, C\}$. Being a supercommutator of two differentiations, this operator is a differentiation.

Claim 3.9: Under these assumptions,

$$C^2 = 3C_{\omega}$$

(3.4)

Proof: Both sides of (3.4) are differentiations, and vanish on $\Lambda^0(M)$. Therefore, to prove (3.4) it suffices to check that $C^2 = 3C_{\omega}$ on $\Lambda^1(M)$. Both $C^2$ and $C_{\omega}$ define $G_2$-invariant map from $\Lambda^1(M)$ to $\Lambda^3(M)$. By Schur’s lemma, these operators are proportional. To show that the coefficient of proportionality is 3, we compute $C^2$ and $C_{\omega}$ on $e_1$ using (3.1).

A similar argument gives the following claim

Claim 3.10: Under the above assumptions, we have

$$\{L_\omega, C^*\} = -3C_{\omega}.$$  

(3.5)

Proof: The operator $C^*$ takes a form

$$C^*(e_{i_1} \wedge e_{i_2} \wedge ...) = \sum_{k_1 < k_2} (-1)^{(i_{k_1} - 1)k_2} C^*(e_{i_{k_1}} \wedge e_{i_{k_2}}) \wedge e_{i_1} \wedge e_{i_2} \wedge ... \wedge \tilde{e}_{i_{k_1}} \wedge ... \wedge \tilde{e}_{i_{k_2}} \wedge ...$$

(3.6)

where $C^*(e_{i_{k_1}} \wedge e_{i_{k_2}})$ is the usual crossed product of vectors $e_{i_{k_1}}, e_{i_{k_2}}$ on the space equipped with a 3-form and a non-degenerate bilinear symmetric form. From (3.6) it is clear that $C^*$ is a second order differential operator on the algebra $\Lambda^*(M)$ (differential operators on a graded commutative algebra are understood in the sense of Grothendieck - see e.g. [V2]). Then $\{L_\omega, C^*\}$ is a first order differential operator. An elementary calculation gives $C^*\omega = 0$. Therefore, $\{L_\omega, C^*\}$ is a differentiation. To compare $\{L_\omega, C^*\}$ with $-3C_{\omega}$, we need to check that $\{L_\omega, C^*\} = -3C_{\omega}$ on $\Lambda^1(M)$. Both of these operators are $G_2$-invariant, and Schur’s lemma implies that they are proportional on $\Lambda^1(M)$. To compute the coefficient of proportionality, it suffices to compute $\{L_\omega, C^*\}, C_{\omega}$ on some vector, e.g. $e_1$. ■
Claim 3.11: Under the above assumptions, $C : \Lambda^3(M) \to \Lambda^4(M)$ is an isomorphism. Moreover, $C\omega = 2*_\omega$.

Proof: Clearly, $C$ preserves the decomposition of $\Lambda^*(M)$ onto $G_2$-invariant summands as in (3.2). We write $\omega$ in orthonormal basis as in (3.1). The equation $C\omega = 2*_\omega$ is given by a direct calculation. Given a 3-form $\theta \in \Lambda^3(M)$ and applying (3.5), we obtain $\Lambda^*(C\theta) = -3(C^*\omega)\theta$. However, $C^*\omega : \Lambda^3(M) \to \Lambda^1(M)$ is an isomorphism, because $C^*_\omega : \Lambda^1(M) \to \Lambda^3(M)$ is non-zero. To prove Claim 3.11, it remains to show that $C$ is an isomorphism on $\Lambda^3(M)$. By Schur’s lemma, for this it suffices to show that $C|_{\Lambda^3(M)}$ is non-zero.

Consider the form $\eta = e_5 \wedge (e_1 \wedge e_2 - e_3 \wedge e_4)$. Clearly, $\Lambda_\omega \eta = 0$ and $L_\omega \eta = 0$. Therefore, $\eta \in \Lambda^3_{27}(M)$.

From (3.6) we find that $C^*(e_1 \wedge e_2 - e_3 \wedge e_4) = 0$, hence $e_1 \wedge e_2 - e_3 \wedge e_4$ lies in $\Lambda^3_{14}(M)$. This gives

$$C(\eta) = C(e_5 \wedge (e_1 \wedge e_2 - e_3 \wedge e_4))$$
$$= C(e_5) \wedge (e_1 \wedge e_2 - e_3 \wedge e_4)$$
$$= (e_1 \wedge e_2 + e_3 \wedge e_4 + e_6 \wedge e_7) \wedge (e_1 \wedge e_2 - e_3 \wedge e_4)$$
$$= e_6 \wedge e_7 \wedge (e_1 \wedge e_2 - e_3 \wedge e_4)$$

(3.7)

We obtain that $C(\eta) \neq 0$. Claim 3.11 is proven.

Remark 3.12: The calculation (3.7) gives

$$C(\eta) = -*_\eta$$

(3.8)

and by Schur’s lemma this equation holds for all $\eta \in \Lambda^3_{27}(M)$.

Proposition 3.13: Let $(M,\omega)$ be a $G_2$-manifold, and $C$ its structure operator. Then $C$ induces isomorphisms

$$\Lambda^i(M) \xrightarrow{C} \Lambda^{i+1}(M),$$

(i = 1, 2, 3, 4, 5).

Proof: By Schur’s lemma, (3.9) is either an isomorphism or zero. For $i = 1, i = 2$ (3.9) is non-zero as follows from Claim 3.9. For $i = 3$, (3.9) is non-zero by Claim 3.11. Using

$$C(\varphi \wedge \psi) = C(\varphi) \wedge \psi + (-1)^{i_1} \varphi \wedge C(\psi),$$

(3.9)
we find that $\ast C \ast$ is Hermitian adjoint to $C$. On the other hand, \ref{eq:isomorphism} is an isomorphism if and only if
\[ \Lambda_{i+1}^7(M) \xrightarrow{C^\ast} \Lambda_i^7(M), \]
is an isomorphism. Using $C^\ast = \ast C \ast$, we obtain that Proposition 3.13 for $i = k$ is implied by Proposition 3.13 for $i = 6 - k$. Therefore, the already proven assertions of Proposition 3.13 for $i = 1, 2, 3$ imply Proposition 3.13 for $i = 4, 5$.

4 Pseudocohomology for $G_2$-manifolds

4.1 De Rham differential on $\Lambda_7^7(M)$

To study the pseudocohomology, we use the following well-known lemma (appearing in a different form in \cite{FU1} and \cite{FU2}).

**Lemma 4.1:** Let $\eta \in \Lambda_k^7(M)$ be a differential form on a holonomy $G_2$-manifold (not necessarily compact), where $0 < k < 5$ is an integer. Fix parallel $G_2$-invariant isomorphisms
\[ \Lambda_i^7(M) \xrightarrow{\tau_{i,k}} \Lambda_j^7(M), \quad (4.1) \]
for all $i = 1, 2, 3, 4, 5$ (by Schur’s lemma, these isomorphisms are well defined, up to a constant).

Denote by $d_7 : \Lambda_7^7(M) \rightarrow \Lambda_{i+1}^7(M)$ the $\Lambda_7^7$-part of the de Rham differential. Then $d_7(\eta) = 0$ if and only if $d_7(\tau_{i,k} \eta) = 0$ for any $i = 1, 2, 3, 4$.

**Proof:** Consider the Levi-Civita connection
\[ \nabla : \Lambda_7^7(M) \rightarrow \Lambda_7^i(M) \otimes \Lambda_7^i(M). \quad (4.2) \]
The operator $d_7$ is obtained as a composition of \ref{eq:connection} and a $G_2$-invariant pairing $\Lambda_7^7(M) \otimes \Lambda_7^7(M) \rightarrow \Lambda_{i+1}^7(M)$. Using an irreducible decomposition of $\Lambda_7^7(M) \otimes \Lambda_7^7(M)$ (see e.g. \cite{Br2}), we find that $\Lambda_7^7(M) \otimes \Lambda_7^7(M)$ contains a unique irreducible summand isomorphic to $\Lambda_{i+1}^7(M)$ as a $G_2$-representation. It is clear that $d_7 : \Lambda_7^7(M) \rightarrow \Lambda_{i+1}^7(M)$ is obtained as a composition of \ref{eq:connection} and the projection to this $\Lambda_{i+1}^7(M)$-summand. Therefore, the following

\footnote{Using Proposition 3.13 we could use the powers of $C$ to define the isomorphisms \ref{eq:isomorphism}.}
Rational homotopy and parallel forms

M. Verbitsky, February 23, 2005

Diagram is commutative, up to a constant multiplier

\[
\begin{array}{c}
\Lambda^k_t(M) \xrightarrow{d_7} \Lambda^{k+1}_t(M) \\
\tau_{i,k} \downarrow \quad \tau_{i+1,k+1} \downarrow \\
\Lambda^i_t(M) \xrightarrow{d_7} \Lambda^{i+1}_t(M).
\end{array}
\]

(4.3)

We obtain that \(\tau_{i+1,k+1}d_7(\eta) = 0\) if and only if \(d_7(\tau_{i,k}\eta) = 0\). This proves Lemma 4.1.

4.2 Computations of pseudocohomology

Theorem 4.2: Let \((M,\omega)\) be a compact \(G_2\)-manifold, \(\mathcal{H}^*(M)\) the space of harmonic forms, and \(\mathcal{H}^*_c(M) \supset \mathcal{H}^*(M)\) the space of pseudoharmonic forms. Then

(i) \(\mathcal{H}^i_c(M) = \mathcal{H}^i(M)\) for all \(i \neq 3, 4\).

(ii) The orthogonal complement\(^2\) \(\mathcal{H}^i_c(M)_{>0}\) to \(\mathcal{H}^i(M)\) in \(\mathcal{H}^i_c(M)\) lies in \(\Lambda^i_{27}(M)\).

(iii) \(* (\mathcal{H}^3_c(M)_{>0}) = \mathcal{H}^4_c(M)_{>0}\). Moreover, \(\mathcal{H}^3_c(M)_{>0}\) is generated by all solutions of the equation \(d\eta = \mu \ast \eta\), for all \(\mu \in \mathbb{C}, \mu \neq 0, \eta \in \Lambda^3_{27}(M)\).

Proof: Consider the orthogonal decomposition \(\mathcal{H}^*_c(M) = \mathcal{H}^*_c(M) \oplus \mathcal{H}^*_c(M)_{>0}\). Since \(\Delta\) preserves \(\mathcal{H}^*_c(M)\), \(\Delta\) acts diagonally on \(\mathcal{H}^*_c(M)\), and \(\mathcal{H}^*_c(M)_{>0}\) is generated by all eigenvectors of \(\Delta\) with non-zero eigenvalue. Therefore, \(d\) preserves \(\mathcal{H}^*_c(M)_{>0}\).

By Corollary 2.23 \(\mathcal{H}^*_c(M)\) is quasi-isomorphic to \(\mathcal{H}^*(M)\). Therefore, cohomology of \(d\) on \(\mathcal{H}^*_c(M)_{>0}\) is zero. Now, Theorem 4.2 (i) is implied by the following claim

Claim 4.3: Let \((M,\omega)\) be a compact \(G_2\)-manifold, and \(\eta \in \mathcal{H}^i_c(M)\) a non-zero exact pseudo-harmonic form. Then \(i = 4\).

Proof: To prove Theorem 4.2 (i) suffices to prove Claim 4.3 for \(i \leq 4\). Indeed, this will imply that \(\mathcal{H}^i(M)_{>0} = 0\) for \(i < 3\), but the Hodge \(*\) operator preserves \(\mathcal{H}^*_c(M)\), and exchanges \(\mathcal{H}^i(M)_{>0}\) and \(\mathcal{H}^{7-i}(M)_{>0}\), hence \(\mathcal{H}^i(M)_{>0} = 0\) for \(i = 1, 2\) implies \(\mathcal{H}^i(M)_{>0} = 0\) for \(i = 5, 6\).

\(^2\)This notation has the following meaning: \(\mathcal{H}^i_c(M)_{>0}\) is a sum of all positive eigenspaces of Laplacian acting on \(\mathcal{H}^i_c(M)\).
Now, Theorem 4.2 (i) is equivalent to Claim 4.3 as we have shown above. The same argument shows that Claim 4.3 for $i \leq 4$ implies Theorem 4.2 (i) and the full statement of Claim 4.3.

Let $\eta = d\alpha$ be a $d$-exact 1-form in $\mathcal{H}^1_c(M)$, $\alpha \in \mathcal{H}^2_c(M)$. Then $C\eta = Cd\alpha = -dC\alpha = 0$ (the middle equation is implied by $d_c\alpha = 0$). Therefore, $C\eta = 0$. However, $C$ is clearly injective on $\Lambda^1$. This proves Claim 4.3 for $i = 1$.

Let now $\eta = d\alpha$ be a $d$-exact 2-form in $\mathcal{H}^2_c(M)$, $\alpha \in \mathcal{H}^1_c(M)$. Using $d_c\eta = 0$, we obtain
\[ \int \eta \wedge \eta \wedge \omega = \int \eta \wedge d\alpha \wedge \omega = -\int d\eta \wedge \alpha \wedge \omega = \int d\eta \wedge \alpha \wedge \omega = 0 \]

(4.4)

Write the decomposition $\eta = \eta_7 + \eta_{14}$ induced by $\Lambda^2(M) \cong \Lambda^2_7(M) \oplus \Lambda^2_{14}(M)$. Then (4.4) gives $dC\eta = dC\eta_7 = 0$. From Lemma 4.1 we infer that $d_7\eta_7 = 0$.

Consider the top degree forms $\eta_7 \wedge d\alpha \wedge \omega = \eta_7 \wedge \eta_7 \wedge \omega$. (4.5) (the equality holds by Schur’s lemma as $\eta_7$ is the $\Lambda^2_7$-part of $\eta = d\alpha$). Since $\Lambda^2_7(M)$ is an irreducible representation of $G_2$, by Schur’s lemma the 2-form $\eta_7 \rightarrow \int \eta_7 \wedge \eta_7 \wedge \omega$ is sign-definite (negative definite, as Claim 3.8 implies). Then $\int \eta_7 \wedge \eta_7 \wedge \omega < 0$ unless $\eta_7 = 0$. However, by (4.5)

\[ \int \eta_7 \wedge \eta_7 \wedge \omega = \int \eta_7 \wedge d\alpha \wedge \omega = -\int d\eta_7 \wedge \alpha \wedge \omega = \int d\eta_7 \wedge \alpha \wedge \omega = 0 \]

as $d_7\eta_7 = 0$. We obtain that $\eta \in \Lambda^2_{14}(M)$. Using Claim 3.8 again, we obtain that $\int \eta \wedge \eta \wedge \omega > 0$ unless $\eta = 0$. However, $\eta$ is exact, hence this integral vanishes, bringing $\eta = 0$. We proved Claim 4.3 for $i = 2$.

Now, let $\eta = d\alpha$ be a $d$-exact 3-form in $\mathcal{H}^3_c(M)$, $\alpha \in \mathcal{H}^2_c(M)$. To finish the proof of Claim 4.3 we need to show that $\eta = 0$.

Since $d^* \alpha$ commutes with $d_c, d_c^*$, we have $d^*\alpha \in \mathcal{H}^1_c(M)$. As we have shown above, $\mathcal{H}^1_c(M) = \mathcal{H}^1(M)$, and therefore $d^*\alpha$ is harmonic. A $d^*$-exact harmonic form vanishes. Therefore, $d^*\alpha = 0$.

Then $0 = d_c \alpha = d^* L_\omega \alpha$. Similarly, $0 = d_c^* \alpha = \Lambda d\alpha$. Using
\[ \Lambda^2(M) \cong \Lambda^2_7(M) \oplus \Lambda^2_{14}(M), \]
write the decomposition $\alpha = \alpha_7 + \alpha_{14}$. Then $L_\omega \alpha = 2 \ast \alpha_7 - \ast \alpha_{14}$ as follows from Claim 3.8. Therefore, $d^* L_\omega \alpha = \ast d(2\alpha_7 - \alpha_{14})$. We obtain that $\alpha$ satisfies the following:
\begin{align*}
    d^* \alpha &= 0, & d(2\alpha_7 - \alpha_{14}) &= 0, & \Lambda d\alpha &= 0.
\end{align*}

(4.6)
Clearly, $d^* \alpha = 0$ is equivalent to $d \ast \alpha = 0$. Also, $\{L_\omega, d\} = 0$ ($\omega$ is closed).

Using $\ast \alpha_7 = \frac{1}{2} \alpha_7 \wedge \omega$, $\ast \alpha_{14} = -\alpha_{14} \wedge \omega$ (Claim 3.8), we rewrite $d \ast \alpha = 0$ as $L_\omega (d\alpha_{14} - \frac{1}{2} d\alpha_7) = 0$. From (4.6) we obtain $L_\omega (d\alpha_{14} - 2 d\alpha_7) = 0$. Comparing these equations, we find

$$L_\omega (d\alpha_{14}) = 0, \quad L_\omega (d\alpha_7) = 0 \quad (4.7)$$

Using Claim 3.8 again, we find that (4.7) implies $d^* \alpha_{14} = d^* \alpha_7 = 0$.

Now, $C^* A^2_{14}(M) = 0$ because $C^*$ is $G_2$-invariant. Using $d^* \alpha = d^* \alpha_7 = 0$, we obtain

$$0 = d^c c \alpha = \{d^*, C^*\} \alpha = d^* C^* (\alpha_{14} + \alpha_7) = d^* C^* \alpha_7 = d^c c \alpha_7.$$  

This implies

$$d^c c \alpha_7 = d^c c \alpha_{14} = 0 \quad (4.8)$$

Applying $d^c = \{d, \Lambda_\omega\}$, we find that (4.8) brings

$$\Lambda_\omega d\alpha_7 = \Lambda_\omega d\alpha_{14} = 0. \quad (4.9)$$

Comparing (4.9) and (4.7), we find that

$$d\alpha_7, d\alpha_{14} \in \Lambda^3_{27}(M). \quad (4.10)$$

This gives $\eta = d\alpha \in \Lambda^3_{27}(M)$. Since $d_c \eta = 0$, we have $dC d\alpha = 0$, and the form $C \eta = C d\alpha$ is closed. Therefore,

$$\int \eta \wedge C \eta = \int d\alpha \wedge C d\alpha = 0. \quad (4.11)$$

However, on $\Lambda^3_{27}(M)$, the form $\eta \mapsto \int \eta \wedge C \eta$ is non-zero (Claim 3.11), hence, by Schur’s lemma, sign-definite. Therefore, (4.11) implies that $\eta = 0$. This proves Claim 4.3 for $i = 3$. We finished the proof of Claim 4.3. The proof of Theorem 4.2 (i) is also finished.

Let $\alpha \in \Lambda^3(M)$, and $\alpha = \alpha_1 + \alpha_7 + \alpha_{27}$ its decomposition induced by (3.2). To prove Theorem 4.2 (ii), we use the following trivial observation:

$$\alpha_1 = \frac{1}{7} L_\omega \Lambda_\omega \alpha, \quad \alpha_7 = \frac{1}{4} \Lambda_\omega L_\omega \alpha. \quad (4.12)$$

Similarly, for $\eta \in \Lambda^4(M)$, $\eta = \eta_1 + \eta_7 + \eta_{27}$, we have

$$\eta_1 = \frac{1}{7} \Lambda_\omega L_\omega \eta, \quad \eta_7 = \frac{1}{4} L_\omega \Lambda_\omega \eta. \quad (4.13)$$

From Remark 3.12 it follows that this form is negative definite.
Assume now that $\alpha \in \mathcal{H}_c^3(M)_{>0}$. Then $d^*\alpha = 0$ as Theorem 4.2 (i) implies. Therefore

$$0 = d_c\alpha = \{L_\omega, d^*\} \alpha = d^*L_\omega \alpha.$$ 

From (4.12), we obtain

$$d^*\omega_7 = \frac{1}{4} d^*\Lambda_\omega L_\omega \alpha = -\Lambda_\omega d_c \alpha = 0 \quad (4.14)$$

This implies

$$d_c \omega_7 = \{d^*, C^*\} \omega_7 = d^* C^* \alpha \quad (4.15)$$

(the last equation holds because

$$\ker C^* \big|_{\Lambda^3(M)} = \Lambda^3_1(M) \oplus \Lambda^3_{27}(M)$$

as $G_2$-decomposition implies). However,

$$d^* C^* \alpha = d^*_c \alpha = 0$$

since $d^* \alpha = 0$. Then (4.15) gives $d^*_c \alpha_7 = 0$. Similarly,

$$d_c \alpha_7 = d^* L_\omega \alpha_7 = d^* L_\omega \alpha \quad (4.16)$$

(here we use

$$\ker L_\omega \big|_{\Lambda^3(M)} = \Lambda^3_1(M) \oplus \Lambda^3_{27}(M)$$

also implied by $G_2$-decomposition). Using

$$0 = d_c \alpha = \{d^*, L_\omega\} \alpha = d^* L_\omega \alpha,$$

we infer from (4.16) $d_c \alpha_7 = 0$. This gives $\alpha_7 \in \mathcal{H}_c^3(M)_{>0}$.

Now, by (4.12),

$$0 = dL_\omega \Lambda_\omega \alpha_7 = L_\omega \Lambda_\omega d\alpha_7 + L_\omega d_c^* \alpha_7 = L_\omega \Lambda_\omega d\alpha_7. \quad (4.17)$$

Using (4.13), we obtain that (4.17) gives $d\alpha_7 \in \Lambda^4_1(M)$. This means that $d\alpha_7 = f \star \omega$, where $f \in C^\infty(M)$ is a function. Therefore, $0 = d^2 \alpha_7 = df \wedge \star \omega$. This leads to $df = 0$, as the map

$$\Lambda^1(M) \xrightarrow{L_\omega} \Lambda^5(M)$$

is clearly injective. Therefore, $\alpha_7$ is harmonic, hence $\alpha_7 = 0$. 

30
We have shown that
\[ H^3_c(M)_{>0} \subset \Lambda^3_1(M) \oplus \Lambda^3_{27}(M). \]
Taking adjoint, we obtain also that
\[ H^4_c(M)_{>0} \subset \Lambda^4_1(M) \oplus \Lambda^4_{27}(M). \]
(4.18)
Take an arbitrary \( \alpha \in H^3_c(M)_{>0} \). Then \( d\alpha \in H^4_c(M)_{>0} \). Using (4.18) and (4.13), we obtain that \( \Lambda d\alpha = 0 \). Then
\[ 0 = d^* \alpha = \{ \Lambda_\omega, d \} \alpha = d\Lambda_\omega \alpha. \]
(4.19)
Since \( \Lambda_\omega \alpha \) is a function, (4.19) gives \( \alpha_1 = 0 \). Then \( \alpha \in \Lambda^3_{27}(M) \). We proved Theorem 4.2 (ii).

Now, every \( \alpha \in \Lambda^3_{27}(M) \) satisfying \( d\alpha = \mu * \alpha \) clearly belongs to \( H^3_c(M) \). Indeed, in this case
\[ L_\omega \alpha = C^* d\alpha = C^* \alpha = 0 \]
because the operators \( C^*, L_\omega \) are \( G_2 \)-invariant, and
\[ d^* \alpha = * d \alpha = * \mu^{-1} d^2 \alpha = 0. \]
because \( d^2 = 0 \). Taking commutators of \( d^* \) with \( L_\omega \) and \( d^* \) with \( C^* \), we find that \( d_\omega \alpha = d^* \alpha = 0 \). To see that such \( \alpha \) generate \( H^3_c(M) \), we use the following lemma, which finishes the proof of Theorem 4.2 (iii).

**Lemma 4.4:** In assumptions of Theorem 4.2 \( H^3_c(M)_{>0} \) is generated by all \( \alpha \in H^3_c(M)_{>0} \) which satisfy \( d\alpha = \mu * \alpha, \; \mu \neq 0 \).

**Proof:** Since \( d_\epsilon, d^* \) commute with the Laplacian, \( H^3_c(M)_{>0} \) is generated by the eigenspaces \( H^3_c(M)|_{\lambda} \) of \( \Delta|_{H^3_c(M)_{>0}} \), which are finite-dimensional. Moreover, \( * d : \Lambda^3(M) \rightarrow \Lambda^3(M) \) also commutes with the Laplacian, hence it acts on the finite-dimensional spaces \( H^3_c(M)|_{\lambda} \). Since
\[ (*d\alpha, \alpha') = \int_M d\alpha \wedge \alpha' = -\int_M \alpha \wedge d\alpha' = -(*d\alpha', \alpha), \]
the operator \( * d \) is skew-Hermitian, hence semisimple. Therefore, \( H^3_c(M)|_{\lambda} \) is generated by its eigenspaces. By Theorem 4.2 (i), \( d^* \) vanishes on \( H^3_c(M) \), hence \( d\alpha \neq 0 \) unless \( \alpha \) is harmonic. Therefore, \( * d \) acts on \( H^3_c(M)|_{\lambda} \) with
non-zero eigenvalues $\mu_i$. We proved Lemma 4.4. The proof of Theorem 4.2 is finished.

Acknowledgements: I am grateful to Gil Cavalcanti, Marisa Fernández, Nigel Hitchin, Dima Kaledin and Jim Stasheff for valuable advice and consultations. Also, Marisa Fernandez found an error in the original proof of Proposition 2.19.
