Abstract: The main concern in city logistics is the need to optimize the movement of goods in urban contexts, and to minimize the multiple costs inherent in logistics operations. Inspired by an application in a medium-sized city in Latin America, this paper develops a bi-objective mixed linear integer programming (MILP) model to locate different types of urban logistics spaces (ULS) for the configuration of a two-echelon urban distribution system. The objective functions seek to minimize the costs associated with distance traveled and relocation, in addition to the costs of violation of time windows. This model considers heterogeneous transport, speed assignment, and time windows. For experimental evaluation, two operational scenarios are considered, and Pareto frontiers are obtained to identify the efficient non-dominated solutions to select the most feasible ones from such a set. A case study of a distribution company of goods for supermarkets in the city of Barranquilla, Colombia, is also used to validate the proposed model. These solutions allow decision-makers to define the configuration of ULS networks for urban product delivery.

Keywords: Urban Logistics Spaces (ULS); two-echelon distribution systems; location; mixed-integer linear programming; multi-objective; case study

1. Introduction

The location of logistics centers in urban areas and the scarcity of alternative transport systems are some of the factors contributing to the inefficient flow of cargo transport in cities. Therefore, the main concern in the general analysis of urban logistics systems is the need to optimize the movement of goods in cities [1]. These flows include a variety of organizations involving both movements of goods and people, mainly when dealing with B2C deliveries [2] or shopping mobility including both personal mobility and freight transport [3]. This systemic vision of urban logistics is needed for all stakeholders, not only of freight transport and supply chains [4,5] but also of urban transport [6], which include public stakeholders, organizers, orchestrators, and control/regulation actors, but also for the users of the public space, i.e., shippers, receivers (mainly companies but also individuals or associations), transport companies, and also citizens being impacted by urban mobility. Moreover, urban logistics deals with a plethora of flows going beyond the last mile of retailers, and including B2B flows, B2C flows, personal mobility flows transporting good, and city management flows, among others [7]. In that context, an efficient use of the resources required for general logistics operations (e.g., number of vehicles, operation times, labor), and the minimization of costs associated to the operation of such urban systems seem of paramount importance as they represent between 15% and 20% of the total operational cost [8]. In the literature, authors have traditionally considered that logistics is a function of costs [9–12].
In recent years sustainability impacts have been present in the debates of decision-makers on urban logistics and distribution of urban goods [4,7,13–16]. Sustainability can be seen in the respect of the three spheres (economic, environmental, and social and their interactions, viability, bearableness and equity) but also while maintaining, dynamically, the four As (Awareness, Act and Shift, Anticipation, Avoidance), and this in a time continuous logic [7]. The main definitions of city/urban logistics deal with the reduction of nuisances of urban freight transport (i.e., congestion, global warming, pollution, and noise) while maintaining or developing urban economic activities and ensuring a good quality of life in cities, which supposes a certain respect of sustainability principles. However, sustainable urban logistics explicitly considering not only the three spheres but also the 4 As and the dynamic and evolving nature of urban logistics is gaining importance since the past decade. Although the economic continuity of an urban logistics solutions is a necessary condition of its success [15,17–19], other criteria need also to be considered in line with the particularities of each urban context to make efficient decisions [16,20]. To make the supply chains stronger, the planning and organization of the logistics spaces must be rethought. In this sense, to improve the flows, a perfect harmony is required between different aspects in relation to the logistic spaces (e.g., location, size, and zoning) [21]. In that context, the ideal location and integration of Urban Logistics Spaces (ULS) are vital for the design of efficient supply chains, which would contribute to the improvement of the transport of goods. ULS can be seen as interfaces between the different stakeholders that allow reorganizing urban goods flows for a better optimization toward meeting sustainability goals [22]. Those ULS can be of different type and nature, and allow different operations [23]. For that reason, locating such facilities needs to consider ULS as a network in a system. However, most literature works are related to optimizing the location of one type of platforms or facilities in a multi-tier network which does not always consider the specificities of urban logistics, mainly the presence of different stakeholders with their decisions and needs, as well as the double systemic nature of urban logistics (a goods transport system inside a more general one: that of urban mobility or even urban dynamics).

The aim of this paper is to propose a methodological approach to support decision-making for ULS location. More precisely, a mixed integer problem able to be solved by linear programming is proposed. The main contribution of the modelling approach is that it combines a multi-objective, multi-level facility location problem with the inclusion of three different types of facilities and that of different stakeholders, who have different objectives. Moreover, and regarding the current research in the field of location models, this paper extends current works by considering heterogeneous fleet of vehicles, relocation costs, and time windows. Furthermore, this paper considers the speed of transport in each arc in the network by calculating speeds for urban areas to avoid the violation of time windows within logistics operations for multiple goods in each node.

The rest of this paper is organized as follows. Section 2 presents a review of literature about urban logistic spaces and facility location problems. Section 3 presents the materials and methods employed in this research, including the description of the problem and the proposed mathematical model. Section 4 presents the results employing random data and the application on case study. Section 5 presents the conclusions and future research lines.

2. Related Literature

Urban logistics spaces (ULS) are defined as facilities intended to optimize the deliveries organization in the city, on the plans, on both functional and environmental viewpoints, by defining transshipment or bulk-break points [24]. They can be seen as interfaces between the inter-urban and urban transport flows, the private and the public sectors, and between shippers, transporters, and receivers [22]. More precisely, ULS allow a reconfiguration of urban freight transport flows for the benefit of all or some of the stakeholders affected by the economic exchange. Therefore, ULS have a particular interest for both researchers and practitioners, as shown by a wide contribution in both scientific literature and professional media. Main works on ULS deal with categorization and characterization (For a recent
review on the subject, see [25]), design and development [23] or impact evaluation [16]. Categorization is mainly developed for description and understanding purposes, evaluation for estimating the impacts of such facilities and design and development to support decisions concerning the conception of deployment of ULS. In that last issue, ULS location has led a particular attention in literature [26–28], relying on the well-known Facility Location Problem (FLP, [29]), and its different variants [30,31]. This problem consists in determining the ideal geographical location to position the facilities [32]. When designing the most suitable transport networks for urban freight distribution, it is important to define both the platform location and the elements of the transport system such as the vehicles and the routing/organizational issues [23]. It is, for any company, a strategic decision of great importance [29] and has direct implications for the achievement of the objectives, in city logistics contexts [33,34], because an inadequate location hinders the good performance of distribution operations [35]. This implies higher logistics costs and possible dissatisfaction of individuals and companies, leading to inefficiencies of the logistics system and, therefore, of the logistics performance in cities.

For the location of any type of ULS, several variables, criteria, and objectives must be considered simultaneously [36]. In particular, the location of logistics centers is a discrete problem that relates a set of alternatives that must be evaluated against a set of weighted criteria that are independent of each other [37]. The best alternative for location is the one that obtains more value considering the diverse criteria, or objectives, according to the preferences and priorities of the decision-maker [38]. In general, the location of ULS is a rare decision, but one that has great impact on the performance of the entire supply chain and that demands special attention from high-level management. In this type of problem, it is possible to consider the existence of several modes of transport, in addition to considering transport with own or subcontracted fleet, qualified labor, schedules and number of trips, transport of multiple type of goods, type of cargo, and reduction of delivery times (lead time) throughout the distribution operation. All these decisions do impact the costs of the entire operation and must be considered when planning, e.g., the fixed costs of opening new facilities and operational distribution costs [39]. In addition to this, the decision to locate ULS involves other issues and objectives that are not easily quantifiable such as: fiscal incentives and tax burdens that differentiate the potential nodes and of course the environmental impact of the operations, which has been considered relevant in the past decade [40].

The location of logistics facilities significantly affects not only urban goods movement activities, but the entire urban environment and the logistics organizations of companies [41], since these facilities represent cargo generators and receivers [42,43]. In this sense, the facility location problem arises in every organization when they require opening a new facility or relocating an existing one [44]. So far, several works focused on the location of the ULS. Some of them from a holistic perspective [45], others focus on studying specific objectives such as: profit [46,47]. Ambrosino and Sciomachen [48] explore minimizing locations and shipping costs through a mixed integer linear programming model. Other papers focus on the location of a single type of logistics space, e.g., [49], while other works consider the location of distribution centers is part of a collaborative supply chain, e.g., [50] or in a sustainability objective, i.e., mixing economic, environmental, and social criteria in a generalized cost function [51]. In addition, the relationship between the location of logistics facilities and vehicle travel distances for shipments associated with the facilities has also been analyzed [52].

Some other conventional approaches to location include heuristics [53], MIP models [54] dynamic programming [55], nonlinear programming [56,57], quadratic programming [58,59], hierarchical analysis process (AHP) [60], and artificial intelligence (AI) techniques [61], such as specialist systems, artificial neural networks (ANNs), metaheuristics or fuzzy set theory [62]. In the recent works, the trend is to consider a large part of the logistics distribution network incorporating the other vertices of the logistics triangle (transport and inventory), to propose increasingly compensatory solutions. In addition,
new considerations such as service level, reliability, and social responsibility [63] have been incorporated into models with stochastic elements and network dynamics.

The configuration of an urban distribution system can be modeled as a multi-tier (or multi-echelon) distribution network [23,64]. The problem consists of locating facilities and defining the flow of products through the network, leading to the well-known family of n-echelon Facility Location Problems (N-FLP) [30,65]. This paper models the problems as a multiple objective mixed-integer linear program (MILP).

Although various approaches and solution methods have been proposed for FLP, the number of works for FLP is lower [30,66], and there is little work on ULS location that considers transport with heterogeneous fleets together with the shipment of multiple goods. Additionally, to the best of our knowledge, there are no papers that consider the combination of logistical transport costs associated with a ULS typology, as it is proposed in this paper, although cost structure is crucial to ensure the economic viability of urban logistics systems since revenue margins are very narrow [67,68]. Inspired by the urban logistics context explained before, the problem considered in this paper extends the current literature by including delivery time windows, and location and relocation costs, allowing the analysis of ULS locations and the consequent urban distribution systems considering optimization criteria from the specific context. Considered costs are related to the relocation of facilities, the distance traveled for transportation of goods, and the penalization of time windows violation. This location problem has not been previously studied in the academic literature, to the best of our knowledge. Moreover, implicitly, preferences of a functional type of ULS are considered, as well as stakeholders of each type of space and dimensions of the infrastructures for the design of logistics networks, as presented in the taxonomy in [25]. This problem is inspired from a real-life situation found in a medium-sized city in the north region of Colombia, being the fourth city in the country in terms of economic importance. In addition, this paper also provides an approximation to the real context of such problems of urban logistics in practice.

3. Materials and Methods

The proposed methodology is based on the interactive, problem-based vision of operational research [69,70]. Indeed, aiming to deal with a real distribution problem, the problem-solving method needs to represent suitably the reality we deal with, and to do that it is important to develop a framework that is related and compared to the reality it aims to represent. This leads to the application of the Ackoff’s problem solving cycle, which can be defined as follows from Ackoff’s [69] considerations (see Figure 1).

![Figure 1. The problem solving cycle of Ackoff extended and adapted (authors’elaboration from Gonzalez-Feliu’s [70], considerations).](image-url)

More precisely, this work aims to model a reality, so for this purpose, it is important to start from a field representing this reality, observe it, and then conceive first the representation of the decision problem, then the model to be solved. The choice of the
field has been made on two main criteria: the first is the suitability of the selected city to have transport systems able to use a network of ULS, the second that of data availability. Then, the city of Barranquilla has been chosen since it is a medium-sized city in the north region of Colombia, being the fourth city in the country in terms of economic importance, presents a city distribution structure that includes various types of ULS, and a multiple-stage data collection procedure was conducted to retrieve information to interactively build the model.

The main purpose of this research being to propose an optimization model and solve it, representing a reality and being replicable to other contexts, an iterative data collection method has been deployed for describing the problem and validating both the model and the solution. To do that, a set of 9 stakeholders (8 companies and 1 public stakeholder) have been interviewed, and several field observations have been carried out. Each stakeholder has been interviewed three times, at different moments, first to define the ULS in Barranquilla and choose the ULS types, second to define and model the transport systems, and third to validate the hypotheses and assumptions of the model. That data collection allowed to define the decision problem (presented in Section 3.1) then the MIP model was developed and solved with linear programming (presented in Sections 3.2 and 4).

3.1. Problem Description

According to published literature, in Colombia, Logistics Centers are understood as equipment strategically located in highly productive regions to concentrate and provide complementary services to the territory’s main activities and work according to the physical integration of the territory, for the strengthening of its production activities and for the consolidation of political-administrative ties that promote territorial competitiveness [71]. In Colombia, the development of the logistics sector has been one of the country’s biggest bets in recent years, in a logical attempt to take advantage of the availability of land and the excellent strategic location of the country’s maritime ports, especially in the northern Caribbean coast (see circle in Figure 2).

![Figure 2. Location of the city of Barranquilla, Colombia.](image)

This paper considers the case of the city of Barranquilla, which is administratively defined as a special, industrial, and port city located in the northern coast of Colombia. In recent years, Barranquilla and its metropolitan area have had a strong vocation of being a logistics, industrial, and specialized services center, whose fundamental task is to act as
a link node for the country with the global dynamic economy. Barranquilla’s privileged strategic position (see Figure 2) would allow logistics spaces to be in this territory, such as inland intermodal terminals (dry ports) connected directly to one or more sea and river ports, and other types of spaces, where logistics and intramodality do play a first-order role. From the aspect of the development of the freeway Circunvalar de la Prosperidad (see Figure 2) as a structuring road axis for economic activity, together with the creation of various industrial areas to host manufacturing companies and logistics services, it is a commitment to the future, with great implications in businesses, technological, and therefore, economic development of the region, which is desired to be materialized in the construction of logistics nodes, in the implementation of urban logistics spaces (ULS), including distribution centers, which allow response to the economic requirements of the region. It is for this reason that the city of Barranquilla and its metropolitan area must be on the frontline and bet on the combined use of the road, rail, and aviation, taking advantage of the role of the ports that future logistics platforms make possible, since the city will host equipment and services of regional and national rank, including offshore extraction platforms.

In the example of Barranquilla, the city has different areas of economic activity, accompanied by the creation of several industrial areas for the reception of manufacturing companies, logistics and specialized services. These types of activities are mainly located in the eastern zone of the district, extending from north to south and the 30th Street, Cordialidad, and Circunvalar Avenue corridors as defined in the Land Management Plan of the city of Barranquilla [72] (see Figure 3). All these spaces act as logistic nodes that provide solutions to the requirements of the region. However, due to the great growth of the city during the past decade, the logistics requirements and the number of vehicles are increasing. For this reason, since 2014, companies are choosing to re-locate their facilities to the periphery of the city. In the literature, some works (e.g., Tricoire and Parragh [73], Raimbault [74], Sakai et al. [75]) consider that logistics spaces should be in metropolitan areas, while other works (i.e., Heitz et al. [45], Monios [76], Heitz and Dablanc [77], Krzysztofik et al. [78]) consider the peripheries of cities as the ideal areas for the location of these facilities to minimize transportation costs, route distances, among other factors.

In this research, three (3) types of urban logistics spaces (ULS) are considered: (a) industrial plants, (b) transshipment centers, and (c) points of sale (as consumption centers), representing a supply chain with two echelons. The transshipment centers are considered as Logistics Consolidation Centers (LCC), according to the taxonomy proposed in [25].

Figure 3. Logistics spaces in the city of Barranquilla, Colombia.
the context of this model, it is important to mention the relationship of the flows of goods according to the three types of spaces mentioned before (see Table 1). The problem to be addressed consists hence in defining the location of transshipment facilities, as well as the flow of products along the production-distribution network.

Table 1. Relationship of flows between ULS.

| Type of ULS | Receive from: | Send to: |
|-------------|---------------|----------|
| Plants i    | Transshipment ULS j | Plant |
| Points of sale c | | Transshipment |
| | | Point of sale |

3.2. Mathematical Model

In order to solve the problem presented previously, let us consider a weighted undirected graph \( G = (N, V) \), where \( N = I \cup J \cup C \) is the set of nodes that are in turn divided into the subsets \( i = \{1, 2, 3, \ldots, I\} \) corresponding to the plants, \( j = \{1, 2, 3, \ldots, J\} \) corresponding to the transshipment ULS, and \( c = \{1, 2, 3, \ldots, C\} \) corresponding to the points of sales; and \( V = V_{ij} \cup V_{jc} \) corresponds to the arcs \( V_{ij} \) and \( V_{jc} \). The distribution process is carried out on vehicles belonging to the set \( k = \{1, 2, 3, \ldots, K\} \) with capacity \( Q_{kp} \) depending on the type of product \( p \). The geographical location of transshipment center \( j \) should be established in order to minimize the costs associated with transport running at speed \( r = \{1, 2, 3, \ldots, R\} \) with suggested speed limits \([l_r, u_r]\) in urban areas, where \( l_r \) and \( u_r \) are, respectively, the minimum and maximum recommended speed for the arcs \((i, j)\) and \((j, c)\). Location of transshipment center \( j \) must correspond to a strategic zoning \( H = \{1, 2, 3, \ldots, h\} \) within a range of coordinates \([LX_{jh}, UX_{jh}]\) and \([LY_{jh}, UY_{jh}]\), as illustrated in Figure 4.

![Figure 4. Representation of the conceptual model.](image)

Speed for urban zones \( V_{ijr} \) and \( V'_{jcr} \) is addressed from the approach applied in [79] for calculating speed in urban areas.

\[
V_{ijr} = \left[l_r + \frac{dc_i + dc_j}{2R}(u_r - l_r)\right] \quad (1)
\]

\[
V'_{jcr} = \left[l_r + \frac{dc_j + dc_c}{2R}(u_r - l_r)\right] \quad (2)
\]
with a penalty cost of \( \gamma \) where \( dc_{\omega} \) the allocation matrices shipment give similar results. Compared to Network and Manhattan distances, while Network and Manhattan distances between the three types of distances. Euclidean distances overestimate the population and Network distances carried out in [80]. These authors show different correlations rationale of this choice is based on the comparative analysis between Manhattan, Euclidean, and Network distances. The relationships between the nodes are defined through the allocation matrices \( \omega_{ij} \) and \( \phi_{jc} \).

The mathematical model is presented next.

**Sets:**
- I: set of plants
- J: set of transshipment urban logistics spaces (ULS)
- C: set of points of sale
- K: set of trips by type of vehicle
- P: set of products
- R: set of speed range
- H: set of zones

**Parameters:**
- \( \gamma_J \): Penalty cost for violation of time windows in \( j \), \( \forall j \)
- \( \gamma_C \): Penalty cost for violation of time windows in \( c \), \( \forall c \)
- \( LX_{jh} \): Lower position in the abscissa of transshipment ULS \( j \) in zone \( h \), \( \forall j, \forall h \)
- \( UX_{jh} \): Upper position in the abscissa of transshipment ULS \( j \) in zone \( h \), \( \forall j, \forall h \)
- \( LY_{jh} \): Lower position in the ordinate of transshipment ULS \( j \) in zone \( h \), \( \forall j, \forall h \)
- \( UY_{jh} \): Upper position in the ordinate of transshipment ULS \( j \) in zone \( h \), \( \forall j, \forall h \)
- \( A_i \): Location in the abscissa of plants \( i \), \( \forall i \)
- \( O_i \): Location in the ordinate of plants \( i \), \( \forall i \)
- \( AC_i \): Location in the abscissa of points of sales \( c \), \( \forall c \)
- \( OC_i \): Location in the ordinate of points of sales \( c \), \( \forall c \)
- \( \omega_{ij} \): Preference matrix from \( i \) to \( j \), \( \forall i, \forall j \)
- \( \phi_{jc} \): Preference matrix from \( j \) to \( c \), \( \forall j, \forall c \)
- \( S_k \): Cost of preparation of the trip in the vehicle \( k \), \( \forall k \)
- \( C\nu_k \): Variable costs per distance traveled in the vehicles of type \( k \), \( \forall k \)
- \( a_c \): Earlier arrival at transshipment ULS \( j \), \( \forall j \)
- \( b_j \): Arrival after the transshipment ULS \( j \), \( \forall j \)
- \( a'_c \): Earlier arrival at point-of-sale \( c \), \( \forall c \)
- \( b'_c \): Arrival after the point-of-sale \( c \), \( \forall c \)
- \( mm_j \): Maximum number of transshipment centers \( j \) in each zone \( h \), \( \forall j, \forall h \)
- \( Q_p \): Product reception capacity at the transshipment center \( j \), \( \forall j \)
- \( d_{jp} \): Demand of product \( p \) in the points of sale \( c \), \( \forall p, \forall c \)
- \( Q_{kp} \): Capacity of vehicle \( k \) according to product type \( p \), \( \forall k, \forall p \)
- \( Cs_{jh} \): Cost of relocating transshipment \( j \) in zone \( h \), \( \forall j, \forall h \)
- \( M \): very large number

**Variables:**
- \( X_{j} \): Opening position in the abscissa of transshipment ULS \( j \), \( \forall j \)
- \( Y_{j} \): Opening position in the ordinate of transshipment ULS \( j \), \( \forall j \)

where \( dc_i, dc_j, \) and \( dc_c \) correspond to the distance of each type of node from the city center. Moreover, \( R \) is the city radius. We assume \( dc_i \) as the distance from the center of the \( h_i \) due to the uncertainty of the distance. Considering the coordinates of the locations of each type of \( N \) node in the arcs \((i, j)\) and \((j, c)\), distances will be treated as Manhattan distances. The rationale of this choice is based on the comparative analysis between Manhattan, Euclidean, and Network distances. These authors show different correlations between the three types of distances. Euclidean distances overestimate the population compared to Network and Manhattan distances, while Network and Manhattan distances give similar results.

In addition, time windows for distribution operations are considered for each transshipment \([a_c, b']\) and for each point of sale \([a_c', b_c']\). Time window violations are admitted with a penalty cost of \( \gamma_J \) and \( \gamma_C \).
The objective function is:

\[
\text{point-of-sale} \sum_{i} \sum_{j} \sum_{k} \text{CV}_{ijk} + \sum_{j} \sum_{c} \sum_{k \geq n} \text{CV}_{jck} + \sum_{j} \sum_{h} C_{sh} \theta_{jh} + \beta \left[ \sum_{j} \gamma_{j}(Va_{j} + Vb_{j}) + \sum_{c} \gamma_{c}(Va_{c} + Vb_{c}) \right]
\]

Subject to:

\[
dx_{ij}^{+} - dx_{ij}^{-} + X_{i} = A_{ij} \omega_{ij} \quad \forall i, \forall j
\]

\[
dy_{ij}^{+} - dy_{ij}^{-} + Y_{i} = O_{ij} \omega_{ij} \quad \forall i, \forall j
\]

\[
ddx_{ik}^{+} - ddx_{ik}^{-} + X_{i} = AC_{ik} \phi_{ik} \quad \forall j, \forall c
\]
\[ ddy_{jc}^+ - ddy_{jc}^- + Y_j = OC_c \phi_{jc} \]  
\[ \forall j, \forall c \]  \( (7) \)

\[-M \delta_j + \sum h X_{jh} \theta_{jh} \leq X_j \leq M \delta_j \sum h X_{jh} \theta_{jh} \]  
\[ \forall j \]  \( (8) \)

\[-M \delta_j + \sum h Y_{jh} \theta_{jh} \leq Y_j \leq M \delta_j \sum h Y_{jh} \theta_{jh} \]  
\[ \forall j \]  \( (9) \)

\[ \sum \delta_j = J - 1 \]  \( (10) \)

\[ \sum \theta_{jh} = 1 \]  
\[ \forall j \]  \( (11) \)

\[ Z_{ijkp} \leq \sum_r W_{ikr} Q_{kp} \]  
\[ \forall i, \forall j, \forall k < n, \forall p \]  \( (12) \)

\[ Z_{jckpu}' \leq \sum_r W_{jckr} Q_{kp} \]  
\[ \forall c, \forall j, \forall k \geq n, \forall p \]  \( (13) \)

\[ \sum_{k=1}^n \sum_r W_{ikr} = \omega_{ij} \]  
\[ \forall i, \forall j \]  \( (14) \)

\[ \sum_{j=1}^n \sum_{k \geq n} W_{jckr} = \Phi_{jc} \]  
\[ \forall j, \forall c \]  \( (15) \)

\[ CV_{ijk} = -M \left( 1 - \sum_r W_{ikr} \right) + S_k + 2Cv_k \left( dx_{ij}^+ + dx_{ij}^- + dy_{ij}^+ + dy_{ij}^- \right) \]  
\[ \forall i, \forall j, \forall k < n \]  \( (16) \)

\[ CV_{jck}' = -M \left( 1 - \sum_r W_{jckr} \right) + S_k + 2Cv_k \left( dx_{ij}^+ + dx_{ij}^- + dy_{ij}^+ + dy_{ij}^- \right) \]  
\[ \forall j, \forall c, \forall k \geq n \]  \( (17) \)

\[ \sum_i \sum_{k \geq n} \sum_p Z_{jckp} \leq Q_{pj} \]  
\[ \forall j \]  \( (18) \)

\[ \sum_{k \geq n} \sum p Z_{jckp} = d_{cp} \]  
\[ \forall c, \forall p \]  \( (19) \)

\[ \sum_n \sum_i Z_{ikp} = \sum_c \sum_{k \geq n} Z_{jckp}' \]  
\[ \forall j, \forall p \]  \( (20) \)

\[ TV_k \geq -M \left( 1 - \sum_r W_{ikr} \right) + 2 \left[ dx_{ij}^+ + dx_{ij}^- + dy_{ij}^+ + dy_{ij}^- \right] \]  
\[ \forall i, \forall j, \forall k < n \]  \( (21) \)

\[ TV_k' \geq -M \left( 1 - \sum_r W_{jckr} \right) + 2 \left[ dx_{ij}^+ + dx_{ij}^- + dy_{ij}^+ + dy_{ij}^- \right] \]  
\[ \forall j, \forall c, \forall k \geq n \]  \( (22) \)

\[ V_{ij} = \sum_r V_{ijr} W_{ikr} \]  
\[ \forall i, \forall j, \forall k < n \]  \( (23) \)
\[ V_{V'jck} = \sum_r V'_{jcr} W'_{jckr} \]
\[
\forall j, \forall c, \forall k \geq n \tag{24}
\]
\[
\sum_i \sum_j \sum_r W_{ijkr} = 0 \quad \forall k \geq n \tag{25}
\]
\[
\sum_j \sum_c \sum_r W_{jckr} = 0 \quad \forall k < n \tag{26}
\]
\[
\sum_p Z_{ijkp} \leq M \sum_r W_{ijkr} \quad \forall i, \forall j, \forall k < n \tag{27}
\]
\[
\sum_j \sum_c \sum_r W'_{jckr} \leq M \sum_r W'_{jckr} \quad \forall j, \forall c, \forall k \geq n \tag{28}
\]
\[

Equation (3) minimizes the costs associated with the vehicle trips by considering the distances traveled according to the location of transshipment, and the costs for re-localization. Equation (4) minimizes the costs for time window violation. Constraints (4), (5), (6), and (7) represent the rectilinear distances over which the connection lines in the supply network are modeled. Constrain (8) and (9) ensure that the areas designated for the opening of transshipments centers are not violated. Constraints (10) serve as an opening key by limiting the number of intermediate nodes that can be opened. Constraints (12) and (13) prevent the violation of vehicle capacity. Constraints (14) and (15) determine the shipment conditions. Equations (16) and (17) calculate the travel costs. Constraints (18) ensures that the quantity of products sent to the ULS specialists does not exceed the quantity of products in the transshipment centers. Constraint (19) ensure compliance with the demand for specialist ULS. Constraint (20) prevent stocks. Constraints (21) and (22) calculate the travel times in each vehicle. Constraints (23) and (24) calculate the speeds assigned on each arc. Constraints (25) and (26) ensure that the vehicle used for the arc \((i,j)\) is not used for the arc \((j,c)\). Constraints (27) and (28) determine that if an arc is realized, a quantity must be distributed. Constraints (29) and (30) calculate the arrival times at each node. Constraints (31), (32), (33), and (34) calculate the time window violations by arrival before and after. Constraints (35) and (36) ensure that an arc is made exactly once. Constraints (37) and (38) ensure that if two or more transshipment centers are in the same zone, they must be separated. Constraints (39) ensure that a transshipment center can be re-located in just one zone. Constraints (40), (41), and (42) define the nature of variables. Constraints (16), (17), (21), (22), (29), and (30) are linear equations transformed from following non-linear equations (43), (44), (45), (46), (47), and (48):

\[ CV_{ijk} = S_k + 2Cv_k \sum_r W_{ijkr} \left( dx_{ij}^+ + dx_{ij}^+ + dy_{ij}^+ + dy_{ij}^+ \right) \quad \forall i, \forall j, \forall k < n \]  
\[ CV'_{jck} = S_k + 2Cv_k \sum_r W'_{jckr} \left( dx_{ij}^+ + dx_{ij}^+ + dy_{ij}^+ + dy_{ij}^+ \right) \quad \forall j, \forall c, \forall k \geq n \]  
\[ TV_k \geq 2 \left[ \sum_i \sum_j \sum_r W_{ijk} \left( \frac{dx_{ij}^+ + dx_{ij}^+ + dy_{ij}^+ + dy_{ij}^+}{v_{ijr}} \right) \right] \quad \forall k < n \]  
\[ TV'_k \geq 2 \left[ \sum_i \sum_j \sum_r W'_{jck} \left( \frac{dx_{ij}^+ + dx_{ij}^+ + dy_{ij}^+ + dy_{ij}^+}{v_{jcr}} \right) \right] \quad \forall k \geq n \]  
\[ Tg_j = \left[ \sum_{i=1}^{n-1} \sum_k \sum_r W_{ijk} \left( \frac{dx_{ij}^+ + dx_{ij}^+ + dy_{ij}^+ + dy_{ij}^+}{v_{ijr}} \right) \right] \quad \forall j \]  
\[ Tg'_c = \left[ \sum_{i=1}^{n-1} \sum_k \sum_r W'_{jck} \left( \frac{dx_{ij}^+ + dx_{ij}^+ + dy_{ij}^+ + dy_{ij}^+}{v_{jcr}} \right) \right] \quad \forall c \]  

4. Results

Two theoretical test scenarios were built to carry out the experiments. The first scenario presents 20 customers, two plants, four intermediaries, and three possible location zones. The second scenario has 15 customers, three plants, six intermediaries, and three location...
zones (see Table 2). Speed variations are applied based on an urban area (two ranks). Although these sets of instances can be considered as small in terms of the computational complexity to run the model, computational times are high. Therefore, the model was run using the Neos Server platform [81]. Results are shown next.

Table 2. Description of benchmark instances.

| Item                                | Number in First Scenario | Number in Second Scenario |
|-------------------------------------|--------------------------|---------------------------|
| Plants                              | 2                        | 3                         |
| Transshipment ULS                   | 4                        | 6                         |
| Point of sale                       | 10                       | 15                        |
| Location zone for transshipment     | 3                        | 3                         |
| ULS                                 |                          |                           |
| Products                            | 2                        | 2                         |
| Speed range                         | 2                        | 2                         |
| Trips/vehicle                       | 20                       | 30                        |

To run the experiments, a set of weighting variations was established and associated with the objectives of minimizing distribution and re-location costs and time window violation costs for the construction of the Pareto frontier. We duplicated the tests for the higher weights of the second objective, due to the trend of the results. The weights, costs, and gap for each variation are shown in Table 3. For the construction of the Pareto fronts, only the results with a gap less than or equal to 4% were considered. This gap corresponds to the approximation value of the best integer solution found by the solver at the end of the optimization process for the given computational time limit. The analysis of these Pareto fronts is presented in the next subsections.

Table 3. Relationship of flows between ULS.

| Weights  | First Scenario Cost | Gap  | Second Scenario Cost | Gap  |
|----------|---------------------|------|-----------------------|------|
| 0.90     | 8410.67             | 28.81% | 15,174.32             | 22.04% |
| 0.80     | 7143.97             | 27.52% | 15,079.73             | 26.11% |
| 0.70     | 7468.16             | 24.25% | 15,079.73             | 29.75% |
| 0.60     | 8250.76             | 26.72% | 13,653                | 31.71% |
| 0.50     | 7684.8              | 4%    | 12,468.81             | 4%   |
| 0.45     | 8232.75             | 4%    | 12,215.5              | 4%   |
| 0.40     | 8270.23             | 4%    | 12,253.54             | 4%   |
| 0.35     | 8250.76             | 25.36% | 13,802.88             | 33.58% |
| 0.30     | 7780.7              | 4%    | 13,598.73             | 4%   |
| 0.25     | 7874.24             | 4%    | 13,163.2              | 4%   |
| 0.20     | 8564.03             | 4%    | 12,308.91             | 4%   |
| 0.15     | 7755.9              | 4%    | 12,578.33             | 4%   |
| 0.10     | 8136.26             | 4%    | 12,682.07             | 4%   |
| 0.05     | 8021.24             | 4%    | 13,039.1              | 4%   |

4.1. Analysis of the First Scenario

For this first scenario, the Pareto front is presented in Figure 5. The minimum cost was obtained with the weights $\alpha = 0.5$ and $\beta = 0.5$. The first objective resulted in a cost of $7684.8$, while for the second objective it was $0$ because no time windows were violated in any of the nodes. The opening coordinates of each transshipment centers are $(12, -70)$, $(11, 40)$, $(10, 40)$, and $(-51, -40)$, respectively (see Figure 6). The arrival times in minutes at each node are: $j_1 = 139$, $j_2 = 75$, $j_3 = 123$, and $j_4 = 78$. The resulting speeds for the process of distribution in the arc $(j,c)$ are extended to the maximum of the time window to minimize the travel speed, resulting in that the vehicles did not significantly exceed the recommended speed limits (see Table 4).
4.1. Analysis of the First Scenario

For this first scenario, the Pareto front is presented in Figure 5. The minimum cost was obtained with the weights $\alpha = 0.5$ and $\beta = 0.5$. The first objective resulted in a cost of $7684.8$, while for the second objective it was $0$ because no time windows were violated in any of the nodes. The opening coordinates of each transshipment centers are $(12, -70)$, $(11, 40)$, $(10, 40)$, and $(-51, -40)$, respectively (see Figure 6). The arrival times in minutes at each node are: $j_1 = 139$, $j_2 = 75$, $j_3 = 123$, and $j_4 = 78$. The resulting speeds for the process of distribution in the arc $(j_c)$ are extended to the maximum of the time window to minimize the travel speed, resulting in that the vehicles did not significantly exceed the recommended speed limits (see Table 4).

![Figure 5. Pareto frontier for the first scenario.](image)

![Figure 6. Results obtained in the first scenario.](image)

Table 4. First scenario: arrival time, trip assignment, and travel speed for arc $(j,c)$.

| Variables         | Point of Sales |
|-------------------|----------------|
|                   | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9   | 10  |
| $d_i$             | 41  | 82  | 89  | 68  | 53  | 96  | 74  | 79  | 119 | 87  |
| $T_{Sc}^e$        | 71  | 112 | 119 | 98  | 83  | 126 | 104 | 109 | 149 | 117 |
| $b_j^c$           | 71  | 112 | 119 | 98  | 83  | 126 | 104 | 109 | 149 | 117 |
| $W_{jckr}$        | 13  | 11  | 10  | 16  | 18  | 15  | 9   | 19  | 17  | 12  |
| $V_{jck}$         | 59  | 62.33 | 65.83 | 68.5 | 69.5 | 65  | 57.22 | 57.78 | 62.33 | 50.44 |

4.2. Analysis of the Second Scenario

For this first scenario, the Pareto front is presented in Figure 7. The minimum cost was obtained with the weights $\alpha = 0.45$ and $\beta = 0.45$. The first objective resulted in a cost of $12,215.5$, while for the second objective it was $0$ because no time windows were violated in any of the nodes. The opening coordinates of each transshipment centers are $(28, -70)$, $(25, 40)$, $(24, 40)$, $(14, -70)$, $(-51, -40)$, and $(-52, -40)$, respectively (see Figure 8). The
arrival times in minutes at each node are: \( j_1 = 150, j_2 = 140, j_3 = 127, j_4 = 128, j_5 = 147 \), and \( j_6 = 117 \). Just as in the first scenario, the resulting speeds for the process of distribution in the arc \((j, c)\) are extended to the maximum of the time window to minimize the travel speed (see Table 5).

**Figure 7.** Pareto frontier for the second scenario.

**Figure 8.** Results obtained in the second scenario.

**Table 5.** Second scenario: arrival time, trip assignment, and travel speed for the arc \((j, c)\).

| Variables | Point of Sales |
|-----------|---------------|
| \( a'_{ij} \) | 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 | 13 | 14 | 15 |
| \( T'_c \) | 112 | 124 | 94 | 146 | 79 | 63 | 67 | 93 | 142 | 115 | 131 | 98 | 125 | 118 |
| \( V'_c \) | 112 | 124 | 94 | 146 | 79 | 63 | 67 | 93 | 142 | 115 | 131 | 98 | 125 | 118 |
| \( W'_j \) | 28  | 26  | 18 | 9   | 29 | 19 | 30 | 27 | 10  | 13  | 24  | 15  | 23  | 11  | 25  |
| \( V'_c_{jk} \) | 59.44 | 63  | 65.83 | 68.5 | 55.67 | 56.78 | 65 | 57.22 | 57.78 | 68.33 | 60.67 | 67.33 | 53.44 | 57.89 | 69.67 | 59.78 |

\[ V'_c_{jk} = 68.5, 55.67, 56.78, 65, 57.22, 57.78, 68.33, 60.67, 67.33, 53.44, 57.89, 69.67, 59.78 \]
4.3. Analysis of the Case Study

To apply the model for real case study, we used a database provided by a company located in Barranquilla, Colombia, dedicated to the supply of products to different supermarkets. The data set consists of 2 plants, 3 transshipment ULS, 3 zones, 15 points of sale, 2 speeds range, 3 products, and 29 trips. The vehicles are split up into four categories (9 vehicles of 35 ton, 3 vehicles of 32 ton, 6 vehicles of 20 ton, 6 vehicles of 8 ton, and 5 vehicles of 4 ton). The demand data are set at 8500 packaging units. There are three types of packaging: $60 \times 40 \times 25$ for large products with a total weight of up to 7 kg. For medium-sized products, the measures are $40 \times 30 \times 25$ with a total weight of up to 12 kg. Finally, for small products, the measures are $60 \times 40 \times 12.5$ with a total weight of up to 10 kg.

Data regarding the actual demand of customer is kept confidential; hence a random allocation was performed for the purpose of this experiment. This randomization was performed for the quantity of packaging for each customer, in addition to the quantity of each type of packaging. The load configuration for each type of vehicle was calculated with the help of Quick Pallet Maker software under the criteria of 99% weight or volume efficiency.

The preparation costs for each trip correspond to the monthly costs of 4 forklifts, 50 logistics assistants, and forklift battery costs. Costs were calculated based on the total number of vehicles and by vehicle type. Likewise, penalty costs for violation of time windows were calculated considering the general trip preparation costs (i.e., penalty costs for each minute corresponds to the cost of one minute of trip preparation). Finally, variable costs are obtained based on the fuel consumption per kilometer traveled. Table 6 presents all these data.

| Vehicle Type | Preparation Costs (COP$) | Fuel Costs (COP$/km) | Load Capacity (Units) |
|--------------|--------------------------|----------------------|-----------------------|
| 35 Ton       | 215,730                  | 1058.292             | 1410                  |
| 32 Ton       | 215,730                  | 857.773              | 1410                  |
| 20 Ton       | 135,405                  | 679.071              | 885                   |
| 8 Ton        | 120,105                  | 417.889              | 785                   |
| 4 Ton        | 62,530                   | 626.834              | 412                   |

The results of the model correspond to the weight combinations $\alpha = (0.3, 0.2, 0.1, 0.05, 0.15, 0.25, 0.45)$ and $\beta = (0.7, 0.8, 0.9, 0.95, 0.85, 0.75, 0.55)$ given by the Neos Server platform. The other combinations of weights did not give any numerical solution; the solver gave a message of “Out of memory”. The Pareto frontier is built with the results. The best selected solution is that with weights $\alpha = 0.05$ y $\beta = 0.95$ with a total cost of COP$12,103,056 (see Figure 9).
5. Conclusions

Urban logistics spaces (ULS) are logistics infrastructures that facilitate transport and goods flows between cities and their surroundings (peripheral areas). Therefore, some general characteristics for the ULS are assumed (e.g., design, dimensions, flows, stakeholders, specific purposes of each ULS), as proposed in for the development of the proposed model. This paper developed a bi-objective mathematical model of two-echelon for the location and distribution of multiple goods in an urban context. Soft time windows were applied to control the arrival at each of the related nodes at each level of the distribution process. In addition, the impact of time windows on the variation of velocities for the travel process...
in each arc is evident. The model was validated with a set of instances corresponding to two theoretical scenarios. A set of variations were generated for the weights associated with the objectives of minimizing costs by distribution and re-location, and the second objective associated with minimizing costs by violation of time windows. The results showed similar behavior for both instances. The variations that assigned greater weight to the first objective (\( \alpha > 0.5 \)) presented results with a gap greater than 20%. On this basis, we decided to duplicate the variations for the values (\( \alpha \leq 0.5 \)). We obtained results with a best integer solution with a gap of 4%. The Pareto frontiers were built for both scenarios using those model outputs. The results selected as optimal solutions from the set of efficient solutions were obtained with (\( \alpha = 0.5; \beta = 0.5 \)) and (\( \alpha = 0.45; \beta = 0.55 \)) or the first and second scenario, respectively. In a second experiment, the model was applied to a real-life case study of a company delivering products to a well-known chain of supermarkets in the city of Barranquilla, Colombia. Numerical results allow the decision-maker to consider the selected locations as strategic points for relocating its urban logistics spaces for supermarket delivery. There is an inverse relationship between the objectives, that is while the costs associated with distribution increase, the time window violations in the nondominated solutions decrease.

After the results, it is to note that locating intermediate facilities and improving the distribution policies, the company avoids failure to deliver on time. These outputs also do help logistics managers and other decision-makers in government to consider quantitative information allowing to define the framework in which urban distribution activities can operate. The proposed model hence contributes to the solution of complex two-echelon production-distribution problems in urban settings. This extends the current state-of-the-art by including delivery time windows, and location and relocation costs, under multiple objectives.

Due to the complexity of the model, approximate solution strategies can be applied for future work that allow efficient results in shorter computational times. A strategy can be derived from working on the problem following decomposition approaches, such as location first and distribution second. Furthermore, the actual routing of vehicles can be included in the distribution process, leading to solve the NP-hard location routing problem (LRP). On another hand, the inclusion of other types of ULS that can be part of the configurations in the defined levels is considered as a research opportunity. This provides a more realistic approach in studies due to the variety of ULS that define the supply chains in different contexts. In addition, more general results can be established for a variety of real-life logistical situations.
