National Key Laboratory of Crop Genetics and Germplasm Enhancement, Key Laboratory for Biology and Genetic Improvement of Soybean (General, Ministry of Agriculture), National Center for Soybean Improvement, Jiangsu Collaborative Innovation Center for Modern Crop Production, Nanjing Agricultural University, Nanjing, China

Alkaline soil has a high pH due to carbonate salts and usually causes more detrimental effects on crop growth than saline soil. Sodium hydrogen exchangers (NHXs) are pivotal regulators of cellular Na\(^+\)/K\(^+\) and pH homeostasis, which is essential for salt tolerance; however, their role in alkaline salt tolerance is largely unknown. Therefore, in this study, we investigated the function of a soybean NHX gene, GmNHX6, in plant response to alkaline salt stress. GmNHX6 encodes a Golgi-localized sodium/hydrogen exchanger, and its transcript abundance is more upregulated in alkaline salt tolerant soybean variety in response to NaHCO\(_3\) stress. Ectopic expression of GmNHX6 in Arabidopsis enhanced alkaline salt tolerance by maintaining high K\(^+\) content and low Na\(^+\)/K\(^+\) ratio. Overexpression of GmNHX6 also improved soybean tolerance to alkaline salt stress. A single nucleotide polymorphism in the promoter region of NHX6 is associated with the alkaline salt tolerance in soybean germplasm. A superior promoter of GmNHX6 was isolated from an alkaline salt tolerant soybean variety, which showed stronger activity than the promoter from an alkaline salt sensitive soybean variety in response to NaHCO\(_3\) stress. Ectopic expression of GmNHX6 in Arabidopsis enhanced alkaline salt tolerance by maintaining high K\(^+\) content and low Na\(^+\)/K\(^+\) ratio. Overexpression of GmNHX6 also improved soybean tolerance to alkaline salt stress. A single nucleotide polymorphism in the promoter region of NHX6 is associated with the alkaline salt tolerance in soybean germplasm. A superior promoter of GmNHX6 was isolated from an alkaline salt tolerant soybean variety, which showed stronger activity than the promoter from an alkaline salt sensitive soybean variety in response to alkali stress, by luciferase transient expression assays. Our results suggested soybean NHX6 gene plays an important role in plant tolerance to alkaline salt stress.

**Introduction**

Saline-alkali soils currently account for 20% of irrigated land (Bouras et al., 2022). Land alkalization has become a major and increasingly serious problem in the world. Compared with neutral salt stress, the high pH environment in alkaline soil destroys soil structure and affects the absorption of essential elements such as phosphorus and iron by plants (Shi and Wang, 2005). Therefore, alkaline salt causes more serious effects than neutral salt stress on...
plants. Soil alkalization can reduce soil osmotic potential, and cause ion imbalance, disrupt physiological processes, inhibit the growth and development of plants, leading to a serious decline in the yield and quality, and even the death of plants (Yang et al., 2011). Saline-alkali stress leads to leaf wilting and chlorosis (Sun et al., 2021), fewer pods, seeds and lower 100-seed weight (He et al., 2020), inhibited nodule development (He et al., 2021) and other phenomena (Chen et al., 2018) of soybean, resulting in soybean growth retardation, and eventually lead to a serious decline in soybean yield (He et al., 2020). Plants can effectively reduce the damage caused by salt-alkali stress through ion selective absorption, compartmentalization and scavenging reactive oxygen species, etc. (Zhu, 2001; Zhang et al., 2019a). Sodium hydrogen exchanger (NHXs) are integral membrane proteins residing in the plasma membrane, endosome (Dragwidge et al., 2019), and vacuole (Sellamuthu et al., 2020), which belong to the monocotyledon/cation/protectant family (Bassil et al., 2011b). NHXs play important roles in regulating of cellular ion homeostasis (Bassil et al., 2019), pH (Reguera et al., 2015), vesicle trafficking (Bassil et al., 2019), protein transport (Dragwidge et al., 2019), auxin transport (Zhang et al., 2020a), salt tolerance (Long et al., 2020), cell turgor and expansion (Walker et al., 1996), as well as growth and development (Bassil et al., 2019) in many species ranging from bacteria to human. In plants, NHX utilizes an H⁺ electrochemical gradient established by (H⁺)-ATPase (in the plasma membrane) and (H⁺)-PPase (in vacuoles) to allow Na⁺/K⁺ exchange for H⁺, to maintain pH and ion homeostasis (Rodríguez-Rosales et al., 2009; Bassil et al., 2012).

In Arabidopsis thaliana, the NHX exchanger family contains eight members which are divided into three subclasses based on their subcellular localization: vacuolar (AtNHX1-AtNHX4), endosomal (AtNHX5 and AtNHX6), and plasma membrane (AtNHX7/SOS1and AtNHX8) localized exchangers (Reguera et al., 2014; Qiu, 2016a). Plasma membrane NHXs (AtNHX7/SOS1and AtNHX8) are required for Na⁺, K⁺, and pH homeostasis, and play an important role in salt tolerance (An et al., 2007; Oh et al., 2010). Vacular membrane NHXs (AtNHX1-AtNHX4) are critical for vacuolar pH and K⁺ homeostasis (Barragán et al., 2012), salt and drought stress responses (Mohgaeb et al., 2014; Zhang et al., 2019b), osmotic adjustment (Quintero et al., 2000), flower development (Bassil et al., 2011b), as well as plant growth and development (Qiu, 2016a). AtNHX5 and AtNHX6 localize to the Golgi and trans-Golgi network (TGN), and are important for plant growth and response to salt stress (Bassil et al., 2011b), maintaining ion and pH homeostasis (Wang et al., 2015), protein transport (Qiu, 2016b), plant growth and development (Lv et al., 2020), and seedling growth (Zhang et al., 2020b). The Arabidopsis nhx5 nhx6 double mutant showed reduced growth, smaller and fewer cells, smaller rosettes and shorter seedlings, late flowering, and increased sensitivity to salinity (Bassil et al., 2011a). The nhx5 nhx6 sup22 triple mutant had short silique and low seed setting rate, but larger seeds. In addition, the triple mutant had numerous smaller protein storage vacuoles (PSVs) and accumulated precursors of seed storage proteins, suggesting that AtNHX5 and AtNHX6 play important roles in seed production, protein trafficking and PSV biogenesis (Wu et al., 2016). A recent report suggests that NHX5 and NHX6 might regulate auxin transport through endoplasmic reticulum (Fan et al., 2018).

There are also few studies on NHX5 or NHX6 from other plant species in addition to Arabidopsis. Overexpression of PaNHX6 from Phoenix dactylifera in Arabidopsis plants enhanced salt tolerance, retained higher chlorophyll and water content, maintained a balanced Na⁺/K⁺ ratio, and increased seed germination under salinity when compared to the wild-type plants (Al-Harrasi et al., 2020). AoNHX6 from Avicennia officinalis showed high expression levels in the roots, and complementation with AoNHX6 improved the tolerance of yeast mutants and Arabidopsis mutants to both NaCl and KCl stress (Krishnamurthy et al., 2019). The ectopic expression of endosomal-type MnNHX6 from Morus notabilis in Arabidopsis and nhx1 yeast mutant can greatly enhance their salt tolerance compared with vacuolar-type MnNHXs (Cao et al., 2020). Up to now, the role of NHX genes in soybean tolerance to salt-alkali stress is largely unknown, except that GmNHX5 is found regulating salt tolerance in a recent study (Sun et al., 2021). Alkaline soils cause damage to plants not only through salt stress, but also through high pH (Shi and Wang, 2005), therefore, alkali stress is more serious than salt stress, while the role of NHX genes in alkali tolerance of soybean remains unclear.

In our previous transcriptomic study (unpublished) using an alkaline salt tolerant wild soybean variety, we identified an alkali-responsive gene (corresponding to Glyma.09G018200 in the reference genome of soybean variety Williams 82), which encodes a sodium/hydrogen exchanger, and is designated as GmNHX6. Here we investigated the role of GmNHX6 in alkali stress by comparing the relative expression level of GmNHX6 gene in alkaline salt tolerant and sensitive soybean varieties, and study the function of this gene in transgenic soybean composite plants and Arabidopsis. The sequence variation in GmNHX6 and its association with alkaline salt tolerance was also analyzed, to gain a better understanding of its role in alkaline salt tolerance. The possible molecular mechanism of GmNHX6 in response to alkaline salt stress was investigated by the content of Na⁺, K⁺, the Na⁺/K⁺ ratio, and promoter luciferase (LUC) assay. This study aims to provide new insights into the role of GmNHX6 in soybean tolerance to alkaline salt stress and the possible underlying mechanisms.

Materials and methods

Soybean accessions and sodic tolerance rating

A total of 60 soybean accessions (Supplementary Table 1), were obtained from the National Center for Soybean Improvement (Nanjing, China). Twelve seeds of each soybean accession were germinated in plastic pots (q10 × 8 cm) filled with sterile nutrient soil, and irrigated with 1/2 Hoagland nutrient solution form bottom, at 28°C (day)/24°C (night) with 14 h (light)/10 h (dark) photoperiod.
Fifteen pots were placed in a plastic tray (55 cm × 36 cm × 8 cm) containing 2L fresh 1/2 Hoagland nutrient solution (pH ≈ 6.5), and the solution was changed every 2 days. After emergence, the seedlings were thinned to four plants in each pot. When the second trifoliate leaves appeared (12-day-old soybean seedlings), plants were treated with 1/2 Hoagland solution containing 0 or 90 mM NaHCO₃. Sixteen days after treatment, the alkaline salt tolerance was determined by Sodic Tolerance Rating (STR) according to the previously published method (Tuyen et al., 2010).

RNA extraction and gene expression analysis

RNA-seq data from different soybean tissues were downloaded from Soybase. To experimentally determine the expression of GmNHX6, tissues were collected from soybean plants grown in vermiculite in greenhouse with controlled temperature (day/night, 28°C/24°C) and light cycle (day/night, 14/10h). Arabidopsis thaliana plants were grown under controlled temperatures of day/night as 22/22°C and light cycle of day/night for 16/8h. Fresh tissues were ground and extracted for total RNA using an RNAprep Pure Plant Kit (Tiangen Biotech, China). The gene specific primers were designed using the Primer Premier 5 software and listed in Table 2. The cDNA was synthesized by the PrimeScript™ 1st Strand cDNA Synthesis Kit (TaKaRa, Japan). The qRT-PCR was conducted using SYBR Premix ExTaq™ II Mix (TaKara, Japan) on a Roche 480 Real-time detection system (Roche Diagnostics, Switzerland) according to the manufacturers’ instructions. Each experiment was performed in triplicates. Transcript levels in soybean plants were calculated relative to the reference gene GmUKN1 (Guan et al., 2014), using the 2^ΔΔCT methods (Livak and Schmittgen, 2001). The expression of GmUKN1 is stable across all samples in this study (Supplementary Table 3). The qRT-PCR of GmNHX6 gene in transgenic A. thaliana was conducted using the OE-2 line (with lowest expression level of GmNHX6) as the control (relative expression = 1) and AtACTIN7 (Miao et al., 2020) as the reference gene. Data was collected from three biological replicates. The amplification efficiencies (E) of primer pairs were estimated (Supplementary Table 2) by qRT-PCR using 1:10, 1:20, 1:40, 1:80, and 1:160 dilutions of cDNA templates, according to the equation: E = [10^{−1/slope}] − 1 (Pfaffl, 2001).

Sequence alignment, phylogenetic analysis, and sequence analysis

The full sequences of GmNHX6 and other NHXs proteins obtained from Phytozome, were used for multiple sequence alignments by ClustalW2. The unrooted phylogenetic tree was then constructed using MEGA 6.0 (Tamura et al., 2013) based on the Maximum Likelihood (ML) algorithm with 1,000 bootstraps. The putative promoter sequence of 2000-bp upstream GmNHX6 was analyzed using the PlantCare. Protein transmembrane topology and signal peptides were predicted from amino acid sequences using Proter database.  

Subcellular localization of GmNHX6

For subcellular localization of GmNHX6 protein, the open reading frame (ORF) of GmNHX6 was amplified by PCR using specific primers (Supplementary Table 2). The PCR product was then introduced into the pAN580 vector, which contains a green fluorescence protein (GFP) reporter gene, under the drive of CaMV 35S promoter for N-terminal GFP fusion (Zhang et al., 2016), using the ClonExpress II One Step Cloning Kit (Vazyme, China) according to the manufacturer's protocol. To further determine the specific subcellular localization of GmNHX6, the fluorescent marker protein, Man1-mCherry, which is characteristic for the cis-Golgi (Tse et al., 2004), was co-expressed with GmNHX6. The transient expression of above proteins in Arabidopsis mesophyll protoplasts was performed following the published methods (Wu et al., 2009). Confocal imaging analysis was performed using a laser scanning microscope (Zeiss LSM780 META, Jena, Germany).

Obtaining and phenotyping of transgenic soybean composite plants

The coding sequence of GmNHX6 from soybean accession M8206 was cloned into pBinGFP, vector under the control of CaMV 35S promoter. The construct containing 35S:GmNHX6 and the empty vector pBinGFP, were separately transformed into Agrobacterium rhizogenes strain K599 (Kereszt et al., 2007), then used to infect soybean hypocotyls of an alkaline salt sensitive soybean variety Tianlong 1, to obtain transgenic soybean composite plants, according to the previously described method (Kereszt et al., 2007). After 20 days of plant growth, the green fluorescence signals of GFP in positive hairy roots were identified at 488 nm wavelength using a stereoscopic fluorescence microscope (Mshot, China), and the non-transgenic roots were cut-off. The transgenic soybean composite plants were treated with 1/2 Hoagland solution containing 0 or 90mM NaHCO₃ for 7 days, then the Soil and Plant Analysis Development (SPAD) value for chlorophyll content (Pérez-Patricio et al., 2018) and leaf relative water content (LRWC) (Zhang and Zhang, 2021) were measured. The SPAD values of the second, third and fourth trifoliate leaves were recorded 10 times each by the

6. https://wlab.ethz.ch/protter/start/
Chlorophyll Meter SPAD-502 Plus (Konica Minolta, Tokyo, Japan), and the average value was calculated as the SPAD value of the plant. To measure LRWC, the fresh weight (FW) of the second, third and fourth trifoliate leaves was recorded, and then the leaves were incubated in sterile water at room temperature for 12 h, and the turgid fresh weight (TFW) was measured. The fully turgid leaves were then dried at 80°C for 72 h and the dry weight (DW) was recorded. LRWC was measured according to the following equation: \( \text{LRWC} = \frac{\text{FW} - \text{DW}}{\text{TFW} - \text{DW}} \times 100\% \). Three biological replications were performed and five independent transgenic plants \((n=3 \times 5=15)\) were measured for each repeat.

### Functional analysis of GmNHX6 in Arabidopsis thaliana

The coding sequence of GmNHX6 from soybean accession M8206 was cloned into pCAMBIA3301 vector under the control of CaMV 35S promoter. The pCAMBIA3301-35S/GmNHX6 vector was introduced into the A. tumefaciens strain EHA105 for A. thaliana transformation using Col-0 wild-type (WT) plants by the floral dipping method (Clough and Bent, 1998). Transgenic plants were screened based on 20 mg L\(^{-1}\) glufosinate (PhytoTech, United States) resistance (Ren et al., 2009). The homozygous T\(_1\) generation plants were subjected to GmNHX6 gene expression analyses and phenotypic evaluation. The Arabidopsis nhx6 T-DNA insertion mutant (stock, SALK-100042C, nhx6, Col-0 background) used in this study was obtained from the Arabidopsis Biological Resource Center.\(^7\)

To measure the seed germination rate of A. thaliana, 36 stratified seeds for each of three independent GmNHX6-overexpressed lines (OE-1, OE-9, and OE-18), as well WT and nhx6 mutant, were plated on 1/2 MS agar medium, or the media supplemented with 150 mM NaCl (Zheng et al., 2021) or 8 mM NaHCO\(_3\) (Zhu et al., 2011), and then placed in a growth chamber under the long-day growth conditions (16 h light/8 h dark cycle at 22°C ± 2°C). The rates of cotyledon greening were measured as seed germination rates after 7 days. To measure the root length and fresh weight of Arabidopsis seedlings, the sterilized seeds of Arabidopsis were vertically grown on 1/2 MS agar medium for 7 days, and then the seedlings were transplanted to fresh 1/2 MS agar medium, or media supplemented with 150 mM NaCl (Zheng et al., 2021) or 8 mM NaHCO\(_3\) (Zhu et al., 2011) for another 10 days. The root length was analyzed using Image J software.\(^8\)

### Determination of ion content

Seven-day-old Arabidopsis seedlings were transplanted to fresh 1/2 MS agar medium, or media supplemented with 150 mM NaCl or 8 mM NaHCO\(_3\), for another 10 days. Then the seedlings were used for Na\(^+\) and K\(^+\) content determination. To determine the ion content, plants were rinsed thoroughly in deionized water, separated into roots and shoots, inactivated at 105°C for 2 h, and then oven dried at 80°C until they attained a constant mass. The 0.1 g dry material was mineralized using 2 ml 10% HNO\(_3\). Then, the microwave digestion system ETHOS T (Milestone, Italy) was used for ion extraction, and the ion contents in the supernatants were analyzed using an Optima 8,000 ICP-OES DV Spectrometer (PerkinElmer, United States) according to the manufacturer’s instructions (Munns et al., 2012). Three biological replications were performed.

### Analysis of sequence variation and regional association study

Nucleotide sequences were downloaded from phytozone v10 (see Footnote 3), and the 2000-bp upstream of the start codon ATG was considered as the promoter region. The full-length coding sequences were amplified using soybean cDNA as template, and the promoter regions were amplified using soybean genomic DNA as template. The amplicons were sequenced at GenScript (Nanjing, China), and sequence variations among soybean accessions were analyzed. Regional association study was performed using TASSEL 5.0 software (Bradbury et al., 2007). The threshold for a significant association was determined using the previously published method (Yang et al., 2014; Wang et al., 2020), which is \( p < 3.3 \times 10^{-2} (1/n, \text{where } n \text{ is the number of markers}) \) in this study.

### Promoter-LUC assays in tobacco leaves

The promoter activities were analyzed by promoter-LUC transient expression assays in tobacco (Nicotiana benthamiana) leaves, according to the procedures described previously (Jin et al., 2021). For vector constructs, the full-length 2-kb promoter regions of M8206 and ZY were amplified, respectively, and the amplicons were inserted into pGreenHO800-LUC to obtain different promoter-LUC vectors. Above constructs with LUC as a reporter, Pro(ZY)-LUC, Pro(M)-LUC, were transformed into A. tumefaciens strain GV3101 that carries pSoup-19, and introduced into tobacco leaves by infiltration. Then, the tobacco seedlings were transferred to 0 or 100 mM NaHCO\(_3\) for 16 h. LUC activity was observed with an in vivo plant imaging system (Berthold LB 985, Germany).

### Statistical analyses

For qRT–PCR analyses, at least four individual plants were pooled per tissue sample, and at least three qRT–PCR reactions (technical replicates) with at least three biological replicates were performed. For phenotypic evaluation, at least 12 individual plants

---

7. http://www.arabidopsis.org
8. https://imagej.nih.gov/ij/
were analyzed per accession, and the exact numbers of individuals \((n)\) are presented in all figure legends. Differences between groups or genotypes were analyzed using two-sided Wilcoxon test, Duncan’s multiple range test or Student’s \(t\)-test by R software and SAS 9.2 (SAS Institute Inc., Cary, NC, United States).

**Results**

**GmNHX6 encodes a Golgi-localized sodium/hydrogen exchanger**

\(GmNHX6\) gene encodes a sodium/hydrogen exchanger consisting of 534 amino acids. Phylogenetic analyses of GmNHX6 with NHX proteins in *Arabidopsis* showed that GmNHX6 is closely related with AtNHX6 (Figure 1A). Prediction of GmNHX6 transmembrane topology displays 12 transmembrane domains (Supplementary Figure 1), sharing high similarities with AtNHX6. GmNHX6 contains four conserved acidic residues (Al-Harrasi et al., 2020) in transmembrane domains (Supplementary Figure 2), which were previously proven to be essential for \(K^+\) transport (Wang et al., 2015). To determine the subcellular localization of GmNHX6, the \(GmNHX6\) gene was expressed in fusion with the \(GFP\) reporter gene, in the pAN580-GFP expression vector. The constructed vector and empty control vector were transferred to the protoplast of *Arabidopsis*, and the location of \(GFP\) or its fusion protein was observed. We found that, \(GFP\) itself was distributed evenly in the cytoplasm and the nucleus, whereas the...
The expression of *GmNHX6* is more upregulated in alkaline salt tolerant soybean in response to NaHCO$_3$ stress

The phenotypic difference between two soybean varieties of M8206 (alkaline salt tolerant) and ZY (alkaline salt sensitive) was obvious under 90 mM NaHCO$_3$ stress (Figure 2A): ZY already showed wilted leaves at 24 h, but the leaves of M8206 were still normal. The leaves of ZY became yellow and dry out at 48 h and more severe at 72 h, while the leaves of M8206 did not show obvious wilting at 48 h until 72 h. The expression patterns of *GmNHX6* in *G. max* (see Footnote 1) showed that the transcript abundance of *GmNHX6* was higher in the young_leaf and root than the other organs (Supplementary Figure 3). The relative expression levels of *GmNHX6* in response to alkaline salt stress (90 mM NaHCO$_3$) in two soybean varieties were investigated using qRT-PCR. *GmNHX6* gene expression was induced by 90 mM NaHCO$_3$ treatment in the roots and leaves of both soybean varieties (Figures 2B,C). The relative expression level of *GmNHX6* gene in the roots of M8206 (alkaline salt tolerant) showed significantly greater increase at 9, 12, 24, and 48 h after 90 mM NaHCO$_3$ treatment than the alkaline salt sensitive soybean variety ZY (Figure 2B), and the relative expression level of *GmNHX6* gene in the leaves of M8206 showed significantly greater increase at 9, 12, and 24 h in response to NaHCO$_3$ treatment than ZY (Figure 2C). There was no significant difference in *GmNHX6* gene expression between two soybean varieties under normal condition (Supplementary Figure 4).
These results suggested that GmNHX6 might play an important role in soybean response to alkaline salt stress.

Overexpression of GmNHX6 improved soybean tolerance to NaHCO₃ stress

Since a greater increase in the expression level of GmNHX6 was observed in alkaline salt tolerant soybean variety than the sensitive variety after NaHCO₃ treatment, we next tested whether overexpression of GmNHX6 could improve soybean tolerance to alkaline salt stress or not. The coding region of GmNHX6 gene was expressed in fusion with GFP (while the empty vector 35S:GFP was used as control), and transformed into soybean hypocotyls to obtain transgenic composite plants, in the genetic background of an alkaline salt sensitive soybean variety Tianlong 1. The positive transgenic composite plants were identified through GFP fluorescence signal in roots (Figure 3A). Under normal condition (0 mM NaHCO₃), all soybean composite plants grew well, with no obvious difference (Figure 3B; Supplementary Figures 5A,E,I). When the transgenic composite soybean plants were treated with 90 mM NaHCO₃ for 7 days, the 35S:GFP-transformed soybean composite plants showed obviously inhibited growth, leaf wilting and chlorosis, while the 35S:GmNHX6-GFP-transformed composite plants had much less damage (Figure 3B; Supplementary Figures 5A,E,I). The expression level of GmNHX6 gene was higher in 35S:GmNHX6-GFP-transformed soybean plants than the 35S:GFP-transformed plants either under 0 or 90 mM NaHCO₃, and GmNHX6 gene expression...
was significantly upregulated at 24 h post 90 mM NaHCO₃ treatment in 35S:GmNHX6-GFP-transformed soybean hairy roots (Figure 3C; Supplementary Figures 5B,E). The average SPAD value for chlorophyll content (Figure 3D; Supplementary Figures 5C,G,K) and the leaf relative water content (LRWC; Figure 3E; Supplementary Figures 5D,H,L) of 35S:GmNHX6-GFP-transformed soybean composite plants were significantly higher than those of the control plants transformed by the 35S:GFP under 90 mM NaHCO₃ treatment. No significant differences were found in SPAD and LRWC between 35S:GmNHX6-GFP-transformed plants and 35S:GFP-transformed plants under normal condition (0 mM NaHCO₃). These results demonstrated that overexpression of GmNHX6 reduced the damage of NaHCO₃ treatment on soybean plants.

**Ectopic expression of GmNHX6 in Arabidopsis enhanced the alkaline salt tolerance by maintaining low Na⁺/K⁺ ratios**

We further investigate the role of GmNHX6 in response to alkaline salt stress by transgenic Arabidopsis plants. GmNHX6 was overexpressed (OE) using the CaMV 35S promoter in Arabidopsis. Seven homozygous transgenic Arabidopsis lines containing 35S:GmNHX6 were obtained at T₃ generation. Then three lines with higher GmNHX6 expression levels (OE-1, OE-18, and OE-9) were selected for further analyses (Supplementary Figure 6). The germination rates of Arabidopsis lines were compared in the absence or presence of NaHCO₃, respectively. The results showed that there was no difference in germination rates between the wild type (WT) and GmNHX6 OE lines under normal condition without NaHCO₃, but the germination rates of GmNHX6 OE lines were significantly higher than that of WT Arabidopsis under NaHCO₃ stress (Figures 4A,B). To further test the effect of NaHCO₃ stress on Arabidopsis, we measured the fresh weight and root length of Arabidopsis. Under normal condition, no significant difference was observed between GmNHX6 OE lines and WT (Figures 4C–E). After 10 days of 8 mM NaHCO₃ treatment, GmNHX6 OE lines showed better growth than WT (Figure 4C): the average fresh weight and root length of GmNHX6 OE lines were significantly larger than those of WT Arabidopsis (Figures 4D,E). These results suggest that overexpression of GmNHX6 enhanced the alkaline salt tolerance in Arabidopsis.

We also compared the content of Na⁺, K⁺, and the Na⁺/K⁺ ratio in the roots and leaves of GmNHX6 OE lines with WT Arabidopsis.
under NaHCO$_3$ treatment and normal conditions (Figure 5). For Na$^+$, under normal conditions, its content in leaf or root was similar between all lines. After NaHCO$_3$ treatment, the leaf Na$^+$ content in the GmNHX6 OE lines was significantly higher than that in the WT Arabidopsis, but the Na$^+$ content in root showed the opposite pattern that OE lines had lower Na$^+$ content than WT (Figure 5A). For K$^+$, its content in both leaf and root of the GmNHX6 OE lines was significantly higher than that in the WT before and after NaHCO$_3$ treatment (Figure 5B). For Na$^+$/K$^+$ ratios, there was no significant difference between GmNHX6 OE lines and WT under normal conditions in both leaves and roots. However, the Na$^+$/K$^+$ ratio of GmNHX6 OE lines was lower than that in the WT (Figure 5C). These results suggested that overexpression of GmNHX6 could improve the alkaline salt tolerance by keeping high K$^+$ content and maintaining low Na$^+$/K$^+$ ratio in plants.

Natural variation in the promoter region of soybean NHX6 is associated with alkaline salt tolerance

We sequenced the coding and promoter regions of soybean NHX6 from 30 wild soybean (15 alkaline salt tolerant and 15 alkaline salt sensitive soybean accessions) and 30 cultivated soybean (15 alkaline salt tolerant and 15 alkaline salt sensitive), respectively (Supplementary Table 1; Supplementary Figure 7). The results showed that only the NHX6 promoter region had sequence variation among 60 soybean accessions. A total of 30 SNPs were found in the 2-kb promoter region of soybean NHX6 (Supplementary Figure 8). Then, a regional association study was performed using the 30 SNPs in the 60 soybean accessions with extreme sodic tolerance rating (STR). Only one SNP (SNP$_{-560}$-S60bp upstream of the start codon) showed significant association with STR by mixed model in EMMAX (Supplementary Figure 9; Supplementary Table 4). Among the 60 soybean accessions, the majority (25 out of 30, 83%) of alkaline salt tolerant accessions had a base “C” at SNP$_{-560}$, while 70% (21 out of 30) alkaline salt sensitive accessions had a base “T” at SNP$_{-560}$ (Supplementary Figure 8). There was a significant difference in alkaline salt tolerance between the two groups of SNP$_{-560}$-C and SNP$_{-560}$-T in 60 soybean accessions, as well as in wild soybean accessions and cultivated soybean accessions (Figures 6A; Supplementary Figure 10). In order to further compare the two types of promoters containing SNP$_{-560}$-C and SNP$_{-560}$-T, the representative promoters were cloned from two soybean varieties, M8206 and ZY, and designated as Pro-M8206 (containing SNP$_{-560}$-C) and Pro-ZY (containing SNP$_{-560}$-T), respectively. The promoter-LUC transient expression assays in tobacco leaves revealed that the activity of Pro-M was significantly stronger than that of Pro-ZY under alkali stress but not control condition (Figures 6B,C), suggesting that Pro-M is more responsive to alkali stress than Pro-ZY, therefore, leading to higher alkali induced expression level of GmNHX6 in the alkaline salt tolerant soybean accessions than sensitive accessions, thus resulting in enhanced alkaline salt tolerance.

Discussion

Soil salinization and alkalization can reduce soil osmotic potential, and cause ion imbalance, disrupt physiological processes, inhibit growth and development of plants, leading to a serious decline in its yield and quality, and even the death of plants (Zhu, 2001; Yang et al., 2011). Soil salinization and alkalization frequently co-occur, but in the saline-alkaline land in mainland China, the soil salinization caused by alkali salts such as NaHCO$_3$ and Na$_2$CO$_3$ is more serious than that caused by neutral salts such as NaCl and Na$_2$SO$_4$ (Yang et al., 2008, 2011). In general, the stress factors of neutral salts are mainly the ion stress of Na$^+$ and osmotic stress of low water potential caused by high salt concentration, but for the alkaline salts, there is an added factor of high pH (Shi et al., 1998). The alkaline soil causes damage to plants not only through salt stress but also through high pH (Shi and Wang, 2005). Therefore, the deleterious effect of high pH stress or salinity alone is significantly less than that of the combined stress of high pH and salinity (Li et al., 2010). There have been lots of progress on plant tolerance to salt stress, while only few reports on alkali salt...
Here, we investigated the role of soybean NHX6 gene in plant tolerance to alkali salt (NaHCO₃), which would broaden our knowledge on alkali salt tolerance.

In plants, sodium hydrogen exchangers allow cation/H⁺ such as Na⁺/H⁺ to transmembrane transport, to regulate pH and maintain ion homeostasis to resist abiotic stress (Rodríguez-Rosales et al., 2009; Bassil et al., 2012). However, there is no report about its role in soybean tolerance to alkali stress. In this study, a sodium/hydrogen exchanger gene from the soybean, *GmNHX6*, was found to be involved in the alkaline salt tolerance of soybean. The expression of *GmNHX6* was induced by NaHCO₃ treatment and more upregulated in alkali salt tolerant soybean (Figure 2), suggesting it is involved in plant responses to alkaline stress. Transgenic soybean composite plants and *Arabidopsis* plants have been previously used to study gene functions in saline-alkaline tolerance (Al-Harrasi et al., 2020; Ketehouli et al., 2021). *GmPKS4* overexpressing soybean composite plants and transgenic *Arabidopsis* plants had increased proline content as well as high antioxidant enzyme activities under salt and salt-alkali stress treatments, compared to the empty-vector-transformed or wild-type ones (Ketehouli et al., 2021). Then we employed transgenic soybean composite plants and *Arabidopsis* to investigate the role of *GmNHX6* in alkaline salt tolerance (Figures 3–5; Supplementary Figure 5). We found that overexpression of *GmNHX6* enhanced the alkaline salt tolerance of soybean and *Arabidopsis*.

Since NHX genes have been shown to play important roles in salt tolerance in a variety of plant species (Kobayashi et al., 2012; Al-Harrasi et al., 2020; Long et al., 2020; Sun et al., 2021), we further analyzed the function of *GmNHX6* in salt tolerance. The germination rates of *GmNHX6* OE lines were significantly higher than that of WT *Arabidopsis* under NaCl stress (Figures 7A, B). At seedling stage, overexpression of *GmNHX6* in *Arabidopsis* increased the average fresh weight and root length under salt stress (Figures 7C–E). We also compared the contents of Na⁺ and K⁺ in the roots and leaves of *Arabidopsis* (Figures 7F–H). Under normal conditions, there is no significant difference in the content of Na⁺ content between WT and OE lines. However, under NaCl treatment, the Na⁺ content in the leaves of the *GmNHX6* OE lines was significantly higher than that in...
the WT, but in the root Na⁺ content was just the opposite (Figure 7F). The K⁺ content of GmNHX6 OE lines was significantly higher than that in the WT Arabidopsis in both leaves and roots (Figure 7G). The Na⁺/K⁺ ratios of the GmNHX6 OE lines were significantly lower than that in the WT Arabidopsis under NaCl treatment (Figure 7H). These results suggest that overexpression of GmNHX6 enhanced salt tolerance by maintaining Na⁺ and K⁺ homeostasis.

Different from salt stress, alkali stress caused by NaHCO₃ and Na₂CO₃ leads to higher pH (Fang et al., 2021). According to the previous studies, the NHXs are important regulators of cellular pH and ion homeostasis (Rodriguez-Rosales et al., 2009; Bassil et al., 2012). NHX-type antiporters utilize the H⁺ electrochemical gradient to facilitate the exchange of H⁺ for cations such as Na⁺ or K⁺, thereby maintaining both pH and ion homeostasis (Sze and Chanroj, 2018). Studies also showed that plants can secrete large amounts of organic acids under alkali stress, which can play a buffer role and maintain intracellular pH stability (Fang et al., 2021). However, further experiments are needed to investigate the role of GmNHX6 in adjusting pH to alleviate alkali salt stress.

K⁺ is an essential macronutrient for plant growth and the most abundant inorganic cation in plant cells. During plant growth and development, K⁺ is involved in the activation of more than 60 enzyme systems, photosynthesis, carbohydrate metabolism and protein synthesis, what's more, K⁺ is a key modulator for cell homeostasis (Zhang et al., 2015a; Kumar et al., 2020). Na⁺ toxicity is one of the main harmful factors of saline-alkali stress (Apse and Blumwald, 2007). In root cells, Na⁺ is compartmentalized into vacuoles, radial transported to the stele cells, and loaded into the xylem, thus establishing the homeostatic control of Na⁺ in the cytosol (Apse and Blumwald, 2007). Plants can maintain high K⁺ content by increasing K⁺ absorption and reducing K⁺ loss (Zhu, 2003). Under saline-alkali stress, plant cells absorb a large amount of Na⁺, resulting in ion toxicity, which not only inhibits photosynthesis, but also inhibits the absorption of essential element such as K⁺ by plants, when Na⁺/K⁺ is too high, resulting in the change of ion homeostasis and metabolic disorder (Zhu, 2003). Therefore, maintaining a relatively high K⁺ content and low Na⁺/K⁺ ratio in plants under salt-alkali stress is a manifestation of salt-alkali tolerance. The NHXs play important roles in maintaining Na⁺ and K⁺ homeostasis have been well documented (Wang et al., 2015; Sun et al., 2021). Previous studies have shown that NHXs can compartmentalize Na⁺ into vacuoles under salt stress, thus maintaining the intracellular ion balance (Feng et al., 2021). Other studies found that vacuolar NHXs can simultaneously catalyze the exchange of Na⁺/H⁺ and K⁺/H⁺ to maintain intracellular ion balance (Sze and Chanroj, 2018). Under salt stress, NHX transporter, such as NHX1, transport sodium ions to and sequester them in the vacuole.
by vesicle transport, and release K⁺ from vacuolar into the cytoplasm (Barragán et al., 2012). In Arabidopsis, AtNHX5 and AtNHX6 are critical to K⁺ homeostasis in Arabidopsis (Wang et al., 2015). GmNHX5 positively regulates salt tolerance by maintaining higher K⁺/Na⁺ ratio in soybean (Sun et al., 2021). In this study, we found that overexpression of GmNHX6 enhanced Arabidopsis tolerance to both alkaline salt (NaHCO₃) and salt (NaCl) stress, by maintaining higher K⁺ content and low Na⁺/K⁺ ratios.

We also obtained a homozygous mutant nhx6 (stock, SALK-100042C), a T-DNA insertion Arabidopsis mutant of AtNHX6 (Supplementary Figure 11). However, nhx6 mutant did not show alkaline salt tolerance or salt tolerance compared with the WT Arabidopsis (Supplementary Figure 12), which is consistent with the previous study by Bassil et al. (2011a) that the phenotype of nhx5 or nhx6 single-knockout line was not different from the WT, while the double mutant nhx5 nhx6 has reduced growth, smaller and fewer cells, and increased sensitivity to salinity. Through the EnsemblPlants database,⁹ we identified a total of 66 genes in the soybean NHX gene family, which might be functionally redundant in soybean tolerance to salt-alkali stress. Soybean germplasm provides a wide range of saline-alkaline tolerance. To explore the natural variation in soybean NHX6 gene, we analyzed the sequence polymorphism of the 2-kb promoter region (Supplementary Figure 13) of NHX6 in 60 soybean accessions, including G. max and G. soja. Only one SNP (SNPₕ₅₆₀) out of a total of 30 SNPs showed significant association with alkaline salt tolerance (STR) by mixed model in EMMAX (Supplementary Table 4). We analyzed the cis-elements of the 2-kb promoter region (Supplementary Figure 13) of GmNHX6 in two soybean accessions, M8206 and ZY. We found that in Pro-M8206 (containing SNPₕ₅₆₀-C), the sequence forms four cis-acting elements around SNPₕ₅₆₀ including Skn-1_motif (GTGAT, −562 to −558 bp), TCATTCT element (−561 to −556 bp), TTGTCAT motif (−564 to −559 bp), and TGTCAT motif (−563 to −559 bp). Skn-1_motif is responsive to abiotic stress and could be used in plant genetic engineering research on abiotic stress tolerance (De Silva et al., 2017; Zhang et al., 2018). TTGTCAT element is involved in light induction (Mazouni et al., 2003). Previous studies showed that TCATTCT element and TGTCAT element are the binding sites of downstream key functional genes. TCATTCT-containing element acted as an enhancer (Perrotti et al., 1996), and was essential for inducible expression of the IL-5 gene (Miao et al., 2006). Tunicamycin (Tm)-activated sXBP1 bound to the TGTCAT element and suppressed XRCC2 expression to prevent tumor proliferation in vivo (Zhao et al., 2021). Interestingly, promoter-LUC transient expression assays in tobacco leaves revealed that the promoter of GmNHX6 from the alkaline salt tolerant soybean variety, Pro-M8206, had a significantly stronger activity than Pro-ZY (from alkaline salt sensitive variety), under alkali stress (Figures 6B,C), suggesting that Pro-M8206 is more responsive to alkali stress than Pro-ZY. Therefore, it is likely that the SNPₕ₅₆₀ might affect the promoter activity under alkali stress by interrupting the relevant cis-acting elements mentioned above. How these cis-acting elements in the promoter of GmNHX6 regulate gene expression in response to alkali stress needs further study.

Conclusion

In summary, GmNHX6 encodes a sodium/hydrogen exchanger. The expression of GmNHX6 was induced by NaHCO₃ stress, and greater increase in its transcript abundance was observed in alkaline salt tolerant than in alkaline salt sensitive soybean variety. Overexpression of GmNHX6 enhanced the alkaline-salt tolerance of soybean composite plants and Arabidopsis. The GmNHX6 overexpressing Arabidopsis lines had higher K⁺ content and lower Na⁺/K⁺ ratio than the wild-type plants under NaHCO₃ stress. Furthermore, a single nucleotide polymorphism in the promoter region of NHX6 is associated with the alkali tolerance in soybean. These findings would help to further understand the role of NHX6 and its regulatory mechanism in soybean tolerance to alkaline-salt stress.

Data availability statement

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/Supplementary material.

Author contributions

 TJ and YL conceived and designed the experiments, interpreted the results, and wrote and revised the manuscript. TJ, JA, HX, JC, LP, RZ, and NW performed the experiments. TJ analyzed the data and generated the pictures. JG and YL interpreted the results, and wrote and revised the manuscript. TJ, YL, and JG conceived and designed the experiments.

Funding

This work was supported by the National Key Research and Development Program of China (2021YFF1001204) and the Core Technology Development for Breeding Program of Jiangsu Province (JBGS-2021-014).

Acknowledgments

We appreciate Xinyuan Huang and Daolong Dou at Nanjing Agricultural University to provide us the vectors of pGreenII0800-LUC and pBinGFP4.
