Abstract

Let $G$ be a simple undirected graph. A broadcast on $G$ is a function $f : V(G) \rightarrow \mathbb{N}$ such that $f(v) \leq e_G(v)$ holds for every vertex $v$ of $G$, where $e_G(v)$ denotes the eccentricity of $v$ in $G$, that is, the maximum distance from $v$ to any other vertex of $G$. The cost of $f$ is the value $\text{cost}(f) = \sum_{v \in V(G)} f(v)$. A broadcast $f$ on $G$ is independent if for every two distinct vertices $u$ and $v$ in $G$, $d_G(u, v) > \max\{f(u), f(v)\}$, where $d_G(u, v)$ denotes the distance between $u$ and $v$ in $G$. The broadcast independence number of $G$ is then defined as the maximum cost of an independent broadcast on $G$.

In this paper, we study independent broadcasts of caterpillars and give an explicit formula for the broadcast independence number of caterpillars having no pair of adjacent trunks, a trunk being an internal spine vertex with degree 2.

Keywords: Independence; Distance; Broadcast independence; Caterpillar.

MSC 2010: 05C12, 05C69.

1 Introduction

All the graphs we consider in this paper are simple and loopless undirected graphs. We denote by $V(G)$ and $E(G)$ the set of vertices and the set of edges of a graph $G$, respectively.

For any two vertices $u$ and $v$ of $G$, the distance $d_G(u, v)$ between $u$ and $v$ in $G$ is the length (number of edges) of a shortest path joining $u$ and $v$. The eccentricity $e_G(v)$ of a vertex $v$ in $G$ is the maximum distance from $v$ to any other vertex of $G$. The minimum eccentricity in $G$ is the radius $\text{rad}(G)$ of $G$, while the maximum eccentricity in $G$ is the diameter $\text{diam}(G)$ of $G$. Two vertices $u$ and $v$ with $d_G(u, v) = \text{diam}(G)$ are said to be antipodal.

A function $f : V(G) \rightarrow \{0, \ldots, \text{diam}(G)\}$ is a broadcast if for every vertex $v$ of $G$, $f(v) \leq e_G(v)$. The value $f(v)$ is called the $f$-value of $v$. Given a broadcast $f$ on $G$, an $f$-broadcast vertex is a vertex $v$ with $f(v) > 0$. The set of all $f$-broadcast vertices is denoted $V_f \uparrow$. If $u \in V_f \uparrow$ is a broadcast vertex, $v \in V(G)$ and $d_G(u, v) \leq f(u)$, we say that $u$ $f$-dominates $v$. In particular, every $f$-broadcast vertex $f$-dominates itself. The cost $\text{cost}(f)$ of a broadcast $f$ on $G$ is given by

$$\text{cost}(f) = \sum_{v \in V(G)} f(v) = \sum_{v \in V_f \uparrow} f(v).$$

A broadcast $f$ on $G$ is a dominating broadcast if every vertex of $G$ is $f$-dominated by some vertex of $V_f \uparrow$. The minimum cost of a dominating broadcast on $G$ is the broadcast domination number of $G$, denoted $\gamma(G)$. A broadcast $f$ on $G$ is an independent broadcast if every $f$-broadcast vertex is $f$-dominated only by itself. The maximum cost of an independent broadcast number of vertex of $V$ is a vertex $v$.

on $G$ is the broadcast independence number of $G$, denoted $\beta_b(G)$. An independent broadcast on $G$ with cost $\beta$ is an independent $\beta$-broadcast. An independent $\beta_b(G)$-broadcast on $G$ is an optimal independent broadcast. Note here that any optimal independent broadcast is necessarily a dominating broadcast.

The notions of broadcast domination and broadcast independence were introduced by D.J. Erwin in his Ph.D. thesis [9] under the name of cost domination and cost independence, respectively. During the last decade, broadcast domination has been investigated by several authors, see e.g. [11, 12, 13, 14, 15, 16, 17], while independent broadcast domination has attracted much less attention.

In particular, Seager considered in [16] broadcast domination of caterpillars. She characterized caterpillars with broadcast domination number equal to their domination number, and caterpillars with broadcast domination number equal to their radius. Blair, Hegernes, Horton and Manne proposed in [1] an $O(nr)$-algorithm for computing the broadcast domination number of a tree of order $n$ with radius $r$.

However, determining the independent broadcast number of trees seems to be a difficult problem. We propose in this paper a first step in this direction, by studying a subclass of the class of caterpillars. Recall that a caterpillar is a tree such that deleting all its pendant vertices leaves a simple path called the spine. The subclass we will consider is the subclass of caterpillars having no pair of adjacent trunks, a trunk being an internal spine vertex with degree 2.

We now review a few results on independent broadcast numbers. Let $G$ be a graph and $A \subset V(G)$, $|A| \geq 2$, be a set of pairwise antipodal vertices in $G$. The function $f$ defined by $f(u) = \text{diam}(G) - 1$ for every vertex $u \in A$, and $f(v) = 0$ for every vertex $v \notin A$, is clearly an independent $|A|(\text{diam}(G) - 1)$-broadcast on $G$.

**Observation 1 (Dunbar, Erwin, Haynes, Hedetniemi and Hedetniemi [8])**

For every graph $G$ of order at least 2 and every set $A \subset V(G)$, $|A| \geq 2$, of pairwise antipodal vertices in $G$, $\beta_b(G) \geq |A|(\text{diam}(G) - 1)$. In particular, for every tree $T$, $\beta_b(T) \geq 2(\text{diam}(G) - 1)$.

An independent broadcast $f$ on a graph $G$ is maximal independent if there is no independent broadcast $f' \neq f$ such that $f'(v) \geq f(v)$ for every vertex $v \in V(G)$. In [9], D.J. Erwin proved the following result (see also [8]).

**Theorem 2 (Erwin [9])**

Let $f$ be an independent broadcast on $G$. If $V_f^+ = \{v\}$, then $f$ is maximal independent if and only if $f(v) = e_G(v)$. If $|V_f^+| \geq 2$, then $f$ is maximal independent if and only if the following two conditions are satisfied:

1. $f$ is dominating, and
2. for every $v \in V_f^+$, $f(v) = \min \{d_G(v, u) : u \in V_f^+ \setminus \{v\}\} - 1$.

Erwin proved that $\beta_b(P_n) = 2(n-2) = 2(\text{diam}(P_n) - 1)$ for every path $P_n$ of length $n \geq 3$ [9].

In [4], Bouchemakh and Zemir determined the independent broadcast number of square grids.

**Theorem 3 (Bouchemakh and Zemir [4])**

Let $G_{m,n}$ denote the square grid with $m$ rows and $n$ columns, $m \geq 2$, $n \geq 2$. We then have:

1. $\beta_b(G_{m,n}) = 2(m + n - 3) = 2(\text{diam}(G_{m,n}) - 1)$ if $m \leq 4$,
2. $\beta_b(G_{5,5}) = 15$, $\beta_b(G_{5,6}) = 16$, and
3. $\beta_b(G_{m,n}) = \lceil \frac{mn}{2} \rceil$ for every $m, n$, $5 \leq m \leq n$, $(m, n) \neq (5, 5), (5, 6)$.
In this paper, we determine the broadcast independence number of caterpillars having no pair of adjacent trunks. The paper is organised as follows. We introduce in the next section the main definitions and a few preliminary results on independent broadcasts of caterpillars. We then consider in Section 3 the case of caterpillars having no pair of adjacent trunks and prove our main result, which gives an explicit formula for the broadcast independence number of such caterpillars. We finally propose a few directions for future research in Section 4.

2 Preliminaries

Let $G$ be a graph and $H$ be a subgraph of $G$. Since $d_H(u, v) \geq d_G(u, v)$ for every two vertices $u, v \in V(H)$, every independent broadcast $f$ on $G$ satisfying $f(u) \leq e_H(u)$ for every vertex $u \in V(H)$ is an independent broadcast on $H$. Hence we have:

**Observation 4** If $H$ is a subgraph of $G$ and $f$ is an independent broadcast on $G$ satisfying $f(u) \leq e_H(u)$ for every vertex $u \in V(H)$, then the restriction $f_H$ of $f$ to $V(H)$ is an independent broadcast on $H$.

A caterpillar of length $k \geq 0$ is a tree such that removing all leaves gives a path of length $k$, called the spine. Following the terminology of [16], a non-leaf vertex is called a spine vertex and, more precisely, a stem if it is adjacent to a leaf and a trunk otherwise. A leaf adjacent to a stem $v$ is a pendant neighbour of $v$. We will always draw caterpillars with the spine on a horizontal line, so that we can speak about the leftmost of rightmost spine vertex of a caterpillar.

Note that a caterpillar of length 0 is nothing but a star $K_{1,n}$, for some $n \geq 1$. The independent broadcast number of a star is easy to determine.

**Observation 5** For every integer $n \geq 1$, $\beta_b(K_{1,n}) = n$.

Indeed, an optimal broadcast $f$ of $K_{1,n}$ is obtained by setting to 1 the $f$-value of every pendant vertex of $K_{1,n}$, if $n > 1$, or of one of the two vertices of $K_{1,1}$. Therefore, in the rest of the paper, we will only consider caterpillars of length $k \geq 1$.

Let $\mathbb{N}^* = \mathbb{N} \setminus \{0\}$. We denote by $CT(\lambda_0, \ldots, \lambda_k)$, $k \geq 1$, with $(\lambda_0, \ldots, \lambda_k) \in \mathbb{N}^* \times \mathbb{N}^{k-1} \times \mathbb{N}^*$, the caterpillar of length $k \geq 1$ with spine $v_0 \ldots v_k$ such that each spine vertex $v_i$ has $\lambda_i$ pendant neighbours. Note that for any caterpillar $CT$ of length $k \geq 1$, diam($CT$) = $k + 2$. For every $i$ such that $\lambda_i > 0$, $0 \leq i \leq k$, we denote by $\ell_i^0, \ldots, \ell_i^{\lambda_i}$ the pendant neighbours of $v_i$. Moreover, we denote by $CT[a,b]$, $0 \leq a \leq b \leq k$, the subgraph of $CT$ induced by vertices $v_a, \ldots, v_b$ and their pendant neighbours. The caterpillar $CT(1,0,2,1,1,2,1,0,3)$ is depicted in Figure 1.

Let $f$ be an independent broadcast on a caterpillar $CT = CT(\lambda_0, \ldots, \lambda_k)$. We denote by $f^*$ the associated mapping from $\{v_0, \ldots, v_k\}$ to $\mathbb{N}$ defined by

$$f^*(v_i) = f(v_i) + \sum_{j=1}^{\lambda_i} f(\ell_i^j), \text{ if } \lambda_i > 0, \text{ and } f^*(v_i) = f(v_i) \text{ otherwise},$$

for every $i$, $0 \leq i \leq k$. Intuitively speaking, when $\lambda_i > 0$, $f^*(v_i)$ gives the “weight” of the star-graph consisting of the vertex $v_i$ together with its pendant neighbours.
We will say that two independent broadcasts $f_1$ and $f_2$ on $CT$ are similar whenever $f_1^r = f_2^r$. Observe that any two similar independent broadcasts have the same cost.

From Observation 1, we get that $\beta_b(CT) \geq 2(k+1)$ for every caterpillar $CT = CT(\lambda_0, \ldots, \lambda_k)$. In particular, the function $f_c$ on $V(CT)$ defined by $f_c(\ell_0^i) = f_c(\ell_1^i) = k + 1$ and $f_c(u) = 0$ for every vertex $u \in V(CT) \setminus \{\ell_0^i, \ell_1^i\}$ is an independent broadcast on $CT$ with cost $2(k + 1)$.

In the following, we will call any independent broadcast $f$ similar to $f_c$ and such that $|V^+_f| = 2$ a canonical independent broadcast.

The following lemma shows that, for any caterpillar $CT = CT(\lambda_0, \ldots, \lambda_k)$, no independent broadcast $f$ on $CT$ with $f(v) > 0$ for some stem $v$ can be optimal.

**Lemma 8** If $CT = CT(\lambda_0, \ldots, \lambda_k)$ is a caterpillar of length $k \geq 1$ and $f$ is an independent broadcast on $CT$ with $f(v_i) > 0$ for some stem $v_i$, $0 \leq i \leq k$, then there exists an independent broadcast $f'$ on $CT$ with $\text{cost}(f') > \text{cost}(f)$.

**Proof.** Since $f(v_i) > 0$ and $f$ is an independent broadcast, we have $f(\ell_0^i) = 0$ for every $j$, $1 \leq j \leq \lambda_i$. Consider the function $f'$ defined by $f'(v_i) = 0$, $f'(\ell_1^i) = f(v_i) + 1$ and $f'(u) = f(u)$ for every vertex $u \in V(CT) \setminus \{v_i, \ell_1^i\}$. Since $d_{CT}(\ell_1^i, u) = d_{CT}(v_i, u) + 1$ for every vertex $u \in V(CT) \setminus \{\ell_1^i\}$, we get that $f'$ is an independent broadcast on $CT$. Moreover, we clearly have $\text{cost}(f') = \text{cost}(f) + 1$.

The following lemma shows that for every optimal independent broadcast on a caterpillar, at least one pendant vertex of each of the end-vertices of the spine is a broadcast vertex.

**Lemma 7** Let $CT = CT(\lambda_0, \ldots, \lambda_k)$ be a caterpillar of length $k \geq 1$. If $f$ is an optimal independent broadcast on $CT$, then $f^*(v_0) - f(v_0) \neq 0$ and $f^*(v_k) - f(v_k) \neq 0$.

**Proof.** We know by Lemma 6 that $f(v_0) = 0$. Suppose, contrary to the statement of the lemma, that $f(\ell_0^i) = 0$ for every $j$, $1 \leq j \leq \lambda_i$. Let $u$ be the $f$-broadcast vertex that dominates $\ell_0^i$ and let $f(u) = x$. By Lemma 6, $u$ is either a leaf or a trunk.

If $u$ is a leaf, say $u = \ell_1^i$, $1 \leq i \leq k$, $1 \leq j \leq \lambda_i$, let $f'$ be the mapping defined by $f'(\ell_0^i) = x + i$, $f'(u) = 0$ and $f'(u') = f(u')$ for every vertex $u' \in V(CT) \setminus \{\ell_0^i, u\}$. Note that every vertex which was $f$-dominated by $u$ is now $f'$-dominated by $\ell_0^i$. The mapping $f'$ is thus an independent $(\text{cost}(f) + i + 1)$-broadcast on $CT$, contradicting the optimality of $f$.

If $u$ is a trunk, say $u = v_i$, $1 \leq i \leq k - 1$, we similarly define a mapping $f'$ by letting $f'(\ell_0^i) = x + i + 1$, $f'(u) = 0$ and $f'(u') = f(u')$ for every vertex $u' \in V(CT) \setminus \{\ell_0^i, u\}$. The mapping $f'$ is thus an independent $(\text{cost}(f) + i + 1)$-broadcast on $CT$, again contradicting the optimality of $f$.

The case $f(\ell_0^i) = 0$ for every $j$, $1 \leq j \leq \lambda_k$, follows by symmetry. □

Observe that Lemma 7 can be extended to trees as follows:

**Lemma 8** Let $T$ be tree and $T'$ be a subtree of $T$, of order at least 2, with root $r$. Let $f$ be an optimal independent broadcast on $T$. If $r$ is an $f$-broadcast vertex, then $T'$ contains at least one other $f$-broadcast vertex. In particular, if $T'$ is a subtree of height 1 (that is, $e_{T'}(r) = 1$), then $f(r) = 0$.

**Proof.** Suppose to the contrary that $f(r) > 0$ and $f(u) = 0$ for every vertex $u \in V(T') \setminus \{r\}$. Let $t' = e_{T'}(r)$ and $\overline{r} = e_{T-(T'-r)}(r)$.

If $f(r) < t'$, the independent broadcast $f'$ given by $f'(v) = f(r)$ for some vertex $v$ in $T'$ with $d_{T'}(r, v) = t'$ and $f'(u) = f(u)$ for every vertex $u \in V'(T) \setminus \{v\}$ is such that $\text{cost}(f') = \text{cost}(f) + f(r)$, contradicting the optimality of $f$.

If $f(r) > \overline{r}$, then $r$ is the unique $f$-broadcast vertex, which implies $\text{cost}(f) < 2(\text{diam}(T) - 1)$, again contradicting the optimality of $f$ by Observation 1.
Hence \( T > f(r) \geq t' \). Let now \( v \) be any neighbour of \( r \) in \( T' \). Since \( T > f(r) \geq t' \), we have \( e_r(v) = e_r(r) + 1 = T + 1 > f_r(v) + 1 \). The function \( f' \) defined by \( f'(r) = 0 \), \( f'(v) = f(r) + 1 \) and \( f'(u) = f(u) \) for every vertex \( u \in V(T) \setminus \{r,v\} \) is therefore an independent broadcast on \( T \) with \( \text{cost}(f') = \text{cost}(f) + 1 \), contradicting the optimality of \( f \).

This completes the proof. \( \square \)

3 Caterpillars with no pair of adjacent trunks

In this section we determine the broadcast independence number of caterpillars with no pair of adjacent trunks. We first introduce some notation and useful lemmas.

We say that an independent broadcast \( f \) of a caterpillar \( CT \) is an optimal non-canonical independent broadcast on \( CT \) if

(i) \( |V_f^+| \neq 2 \) or \( f^* \neq f^*_c \) (\( f \) is non-canonical), and

(ii) for every independent broadcast \( f' \) on \( CT \) with \( |V_f^+| \neq 2 \) or \( f'^* \neq f^*_c \), \( \text{cost}(f) \geq \text{cost}(f') \) (\( f \) is optimal among all non-canonical independent broadcasts).

Let \( CT = CT(\lambda_0, \ldots, \lambda_k) \) be a caterpillar of length \( k \geq 1 \) with no pair of adjacent trunks. We denote by

\[ \lambda(CT) = \sum_{i=0}^{i=k} \lambda_i \]

the number of leaves of \( CT \), and by

\[ \tau(CT) = |\{i \mid 1 \leq i \leq k - 1 \text{ and } \lambda_i = 0\}| \]

the number of trunks of \( CT \).

We will compute the broadcast independence number of a caterpillar with no pair of adjacent trunks by counting the number of some specific patterns. More precisely, we say that a pattern of length \( p + 1 \), \( \Pi = \pi_0 \ldots \pi_p \), \( p \geq 0 \), \( \pi_i \in \mathbb{N} \) for every \( i, 0 \leq i \leq p \), occurs in a caterpillar \( CT = CT(\lambda_0, \ldots, \lambda_k) \) if there exists an index \( i_0, 0 \leq i_0 \leq k - p \), such that \( CT[i_0, i_0 + p] = CT(\pi_0, \ldots, \pi_p) \), that is, \( \lambda_{i_0+j} = \pi_j \) for every \( j, 0 \leq j \leq p \). We will also say that the caterpillar \( CT \) contains the pattern \( \Pi \) and that the subgraph \( CT(\lambda_{i_0}, \ldots, \lambda_{i_0+p}) \) of \( CT \) is an occurrence of the pattern \( \Pi \). For instance, the caterpillar \( CT(1,0,2,1,1,2,1,0,3) \), depicted on Figure 1, contains once the pattern 211 and twice the pattern 10.

We now extend the notation for patterns as follows:

- By \( \pi_i^+ \), we mean a spine vertex having at least \( \pi_i \) pendant neighbours;
- By \( \pi_i^- \), we mean a spine vertex having at most \( \pi_i \) pendant neighbours;
- By \( \{\Pi\} \), we mean that the pattern \( \Pi \) occurs and starts at the leftmost stem \( v_0 \),
- By \( \{\Pi, \Pi'\} \), we mean that the pattern \( \Pi \) occurs and ends at the rightmost stem \( v_k \),
- By \( \{\Pi, \Pi'\} \), we mean either the pattern \( \Pi \) or the pattern \( \Pi' \).
- By \( \pi_0(\pi_1\pi_2)^r \pi_3 \), we mean a maximal pattern of the form

\[ \pi_0\pi_1\pi_2\pi_3 \text{ or } \pi_0\pi_1\pi_2\ldots\pi_1\pi_2\pi_3, \]

where maximal here means that the subpattern \( \pi_1\pi_2 \) is repeated at least once and as many times as possible.
- By \( \pi_0(\pi_1\pi_2)^r \pi_3 \), we mean a maximal pattern of the form

\[ \pi_0\pi_3, \pi_0\pi_1\pi_2\pi_3 \text{ or } \pi_0\pi_1\pi_2\ldots\pi_1\pi_2\pi_3, \]

where maximal here means that the subpattern \( \pi_1\pi_2 \) is repeated as many times as possible.
We can also combine these notations, so that, for instance, $\pi^+_i$ denotes that the rightmost stem $v_k$ has at least $\pi_i$ pendant neighbours, and $\{\pi_i, \} \Pi$ denotes either the pattern $\pi_i \Pi$ or the pattern $\{\Pi$. One can check that the caterpillar $CT(1, 0, 2, 1, 2, 0, 2, 0, 2, 0, 3)$ contains once each of the four patterns $[1, 3]$, $2^+ \pi^+_1$ and $2111^+$, twice the pattern $0[2, 3]$, and thrice the pattern $1^+0(20)^+1^+$, namely on the sub-caterpillar $CT(1, 0, 2, 0, 2, 0, 2, 0, 3)$ with explicit pattern $1020202$.

For any pattern $\Pi$ and any caterpillar $CT$, we will denote by $\#CT(\Pi)$ the number of occurrences of the pattern $\Pi$ in $CT$. Moreover, if $M$ is an occurrence of $\Pi$ in $CT$, we define the value

$$\alpha_1(M) = \max\{0, \#M(1) - 1\},$$

that is, the number of stems $v_i$ in $M$ with $\lambda_i = 1$ minus 1—or 0 if $M$ contains no such stem—, and the value

$$\alpha_2(M) = \alpha_1(M) + \#M([1^+] + \#M(1^+)),$$

that is, $\alpha_1(M)$ plus 0, 1 or 2, depending on whether $M$ contains no end-vertex of $CT$, one end-vertex of $CT$ or both end-vertices of $CT$, respectively.

We then extend the functions $\alpha_1$ and $\alpha_2$ to the whole caterpillar $CT$ by setting

$$\alpha_1(CT; \Pi) = \sum_{M \text{ occurrence of } \Pi} \alpha_1(M)$$

and

$$\alpha_2(CT; \Pi) = \sum_{M \text{ occurrence of } \Pi} \alpha_2(M).$$

Finally, for any caterpillar $CT$, we define the value $\beta^*(CT)$ as follows:

$$\beta^*(CT) = \lambda(CT) + \tau(CT) + \#CT([1^+, [1^+, []) + \alpha_1(CT; 1^+2^-(02^+)^+1^+) + \alpha_2(CT; 02^-(02^+)^*0) + \alpha_2(CT; 2^-(02^+)^*0) + \alpha_2(CT; 02^-(02^+)^*]).$$
Sample patterns involved in the above formula are illustrated in Figure 2. In the figure, a pattern with a line to the left or right hand side of its spine cannot occur at the left or right end of the caterpillar, respectively. A pattern with a dashed line to the left or right hand side of its spine can occur at the left or right end of the caterpillar, respectively, or in the middle of the caterpillar. A dashed edge is an optional edge (used for pattern 2−, corresponding to a spine vertex with either one or two pendent neighbours).

Let us say that two distinct occurrences of patterns overlap if they share a common vertex. Due to the specific structure of the patterns used in the above formula (and, in particular, of the maximality of the number of repetitions of subpatterns of the form Π+ or Π∗), we have the following:

**Observation 9** In every caterpillar CT of length k ≥ 1,

1. no occurrence of the pattern 02−(02−)∗0 can overlap with an occurrence of a pattern {1+, [1{1+},]}, 1+2−(02−)+r1+, 02−(02−)∗0, [2−(02−)+r]+0 or 02−(02−)∗r,
2. no occurrence of the pattern [2−(02−)+r]0 can overlap with an occurrence of a pattern {1+, [1{1+},]}, or 1+2−(02−)+r1+,
3. no occurrence of the pattern 02−(02−)∗r] can overlap with an occurrence of a pattern {1+, [1{1+},]} or 1+2−(02−)+r1+,
4. if two occurrences of the pattern [2−(02−)+r]0 and 02−(02−)∗r] overlap, then CT is a caterpillar with pattern [2−(02−)+r]∗.

We first prove that every caterpillar with no pair of adjacent trunks admits an independent broadcast f with cost(f) = β∗(CT).

**Lemma 10** Every caterpillar CT = CT(λ0, ..., λk) of length k ≥ 1, with no pair of adjacent trunks, admits an independent broadcast f with cost(f) = β∗(CT).

**Proof.** We will construct a sequence of independent broadcasts f1, ..., f4, step by step, such that cost(f4) = β∗(CT). Each independent broadcast fi, 2 ≤ i ≤ 4, is obtained by possibly modifying the independent broadcast f1−1 and is such that cost(f1) ≥ cost(f1−1). Moreover, for each independent broadcast fi, 1 ≤ i ≤ 4, we will have f1(v) = 0 whenever v is a stem. These modifications are illustrated in Figures 3 and 4 using the same drawing conventions as in Figure 2. Only useful broadcast values are given in these figures. These figures should help the reader to see that all the proposed modifications lead to a new valid independent broadcast.

**Step 1.** Let f1 be the mapping defined by f1(v) = 1 if v is a pendent vertex or a trunk, and f1(v) = 0 otherwise. Clearly, f1 is an independent broadcast on CT with

\[
\text{cost}(f_1) = \lambda(CT) + \tau(CT).
\]

**Step 2.** Let f2 be the mapping defined by f2(v) = 2 if v = ℓi for some i, 0 ≤ i ≤ k, such that (i) λi = 1, (ii) i = 0 or λi−1 ≥ 1, and (iii) i = k or λi+1 ≥ 1, and f2(v) = f1(v) otherwise (see Figure 3(a)). Again, f2 is an independent broadcast on CT with

\[
\text{cost}(f_2) = \text{cost}(f_1) + \#_{CT}({1^+, [1{1^+},]}).
\]

**Step 3.** Suppose that CT contains the pattern 1+2−(02−)+r1+, of length 2r + 3, and let M = CT[i0, i0+2r+2] be the corresponding occurrence of this pattern. We thus have f2(v) = 1 for every trunk of M and for every pendent neighbour of a stem vertex vj on M with i0 + 1 ≤ j ≤ i0 + 2r + 1. Hence, the cost of the restriction f′2 of f2 to M is

\[
\text{cost}(f′_2) = f′_2(v_{i0}) + \lambda(M[i0 + 1, i0 + 2r + 1]) + \tau(M) + f′_2(v_{i0+2r+2}).
\]

We modify f2 as follows, to obtain f3. If the subgraph M[i0 + 1, i0 + 2r + 1] contains a stem vertex vi with λi = 1, we let

\[
\text{cost}(f_3) = \text{cost}(f_2) + \lambda(M[i0 + 1, i0 + 2r + 1]) + \tau(M) + f_3(v_{i0+2r+2}).
\]

We will construct a sequence of independent broadcasts f1, ..., f4, step by step, such that cost(f4) = β∗(CT). Each independent broadcast fi, 2 ≤ i ≤ 4, is obtained by possibly modifying the independent broadcast f1−1 and is such that cost(f1) ≥ cost(f1−1). Moreover, for each independent broadcast fi, 1 ≤ i ≤ 4, we will have f1(v) = 0 whenever v is a stem. These modifications are illustrated in Figures 3 and 4 using the same drawing conventions as in Figure 2. Only useful broadcast values are given in these figures. These figures should help the reader to see that all the proposed modifications lead to a new valid independent broadcast.

**Step 1.** Let f1 be the mapping defined by f1(v) = 1 if v is a pendent vertex or a trunk, and f1(v) = 0 otherwise. Clearly, f1 is an independent broadcast on CT with

\[
\text{cost}(f_1) = \lambda(CT) + \tau(CT).
\]

**Step 2.** Let f2 be the mapping defined by f2(v) = 2 if v = ℓi for some i, 0 ≤ i ≤ k, such that (i) λi = 1, (ii) i = 0 or λi−1 ≥ 1, and (iii) i = k or λi+1 ≥ 1, and f2(v) = f1(v) otherwise (see Figure 3(a)). Again, f2 is an independent broadcast on CT with

\[
\text{cost}(f_2) = \text{cost}(f_1) + \#_{CT}({1^+, [1{1^+},]}).
\]

**Step 3.** Suppose that CT contains the pattern 1+2−(02−)+r1+, of length 2r + 3, and let M = CT[i0, i0+2r+2] be the corresponding occurrence of this pattern. We thus have f2(v) = 1 for every trunk of M and for every pendent neighbour of a stem vertex vj on M with i0 + 1 ≤ j ≤ i0 + 2r + 1. Hence, the cost of the restriction f′2 of f2 to M is

\[
\text{cost}(f′_2) = f′_2(v_{i0}) + \lambda(M[i0 + 1, i0 + 2r + 1]) + \tau(M) + f′_2(v_{i0+2r+2}).
\]

We modify f2 as follows, to obtain f3. If the subgraph M[i0 + 1, i0 + 2r + 1] contains a stem vertex vi with λi = 1, we let

\[
\text{cost}(f_3) = \text{cost}(f_2) + \lambda(M[i0 + 1, i0 + 2r + 1]) + \tau(M) + f_3(v_{i0+2r+2}).
\]
(a) From $f_1$ to $f_2$

(b) From $f_2$ to $f_3$, pattern $1^+201021^+$, $\text{cost}(f'_3) = \text{cost}(f'_2) + (1 - 1)$

(c) From $f_2$ to $f_3$, pattern $1^+2010201011^+$, $\text{cost}(f'_3) = \text{cost}(f'_2) + (3 - 1)$

Figure 3: Proof of Lemma 10 from $f_1$ to $f_3$
• $f_3(t_{i_0+1}^1) = 2$ if $\lambda_{i_0+1} = 1$,
• $f_3(t_{i_0+2r+1}^1) = 2$ if $\lambda_{i_0+2r+1} = 1$,
• $f_3(t_{i_0+2j+1}^1) = 3$ (and $f_3(t_{i_0+2j+1}^2) = 0$ if $\lambda_{i_0+2j+1} = 2$) for every $j$, $1 \leq j \leq r - 1$,
• $f_3(v_{i_0+2}) = 0$ for every $j$, $1 \leq j \leq r$,

(see Figure 3(b) and (c)). The cost of the restriction $f'_3$ of $f_3$ on $M$ is then

$$\text{cost}(f'_3) = \text{cost}(f'_2) + \max\{0, \#M[i_0+1,i_0+2r+1]\} - 1 = \text{cost}(f'_2) + \alpha_1(M).$$

By Observation 9, two occurrences of the pattern $1^+2^-02^-+1^+$ can only overlap on their end-vertices. Therefore, doing the above modification for every occurrence of the pattern $1^+2^-02^-+1^+$ in $M$, the so-obtained independent broadcast $f_3$ satisfies

$$\text{cost}(f_3) = \text{cost}(f_2) + \alpha_1(M).$$

**Step 4.** Suppose first that $CT$ contains the pattern $02^-(02^-)^r0$, of length $2r + 3$, and let $M = CT[i_0,i_0 + 2r + 2]$, $i_0 \geq 1$, $i_0 + 2r + 2 \leq k - 1$, be the corresponding occurrence of this pattern. We thus have $f'_2(v) = 1$ for every trunk of $M$ and for every pendant neighbour of a stem vertex $v_j$ on $M$ with $i_0 + 1 \leq j \leq i_0 + 2r + 1$. Hence, the cost of the restriction $f'_3$ of $f_3$ to $M$ is

$$\text{cost}(f'_3) = f'_3(v_{i_0}) + \lambda(M) + \tau(M[i_0 + 1,i_0 + 2r + 1]) + f'_3(v_{i_0+2r+2}).$$

We modify $f_3$ as follows, to obtain $f_4$. If the subgraph $M[i_0 + 1,i_0 + 2r + 1]$ contains a stem vertex $v_i$ with $\lambda_i = 1$, we let

• $f_4(t_{i_0+2j+1}^1) = 3$ (and $f_4(t_{i_0+2j+1}^2) = 0$ if $\lambda_{i_0+2j+1} = 2$) for every $j$, $0 \leq j \leq r$,
• $f_4(v_{i_0+2}) = 0$ for every $j$, $0 \leq j \leq r$,

(see Figure 4(a)). The cost of the restriction $f'_4$ of $f_4$ on $M$ is then

$$\text{cost}(f'_4) = \text{cost}(f'_3) + \max\{0, \#M(1)\} - 1 = \text{cost}(f'_3) + \alpha_2(M).$$

Suppose now that $CT$ contains the pattern $[2^-02^-]^r0$, of length $2r + 2$, and let $M = CT[0,2r + 1]$ be the corresponding occurrence of this pattern. Doing the same type of modification as above (see Figure 4(b)), the cost of the restriction $f'_4$ of $f_4$ on $M$ is then

$$\text{cost}(f'_4) = \text{cost}(f'_3) + \max\{0, \#M(1)\} + 1 = \text{cost}(f'_3) + \alpha_2(M).$$

Finally, if $CT$ contains the pattern $02^-(02^-)^r0$ and $CT$ is not a caterpillar with pattern $[2^-02^-]^r0$, the same type of modification leads to the same property.

By Observation 9, no two occurrences of the patterns $02^-(02^-)^r0$ and $[2^-02^-]^r0$ (or $02^-(02^-)^r0$ and $02^-(02^-)^r0$) can overlap. Therefore, doing the above modification for every occurrence of these patterns in $M$, the so-obtained independent broadcast $f_4$ satisfies

$$\text{cost}(f_4) = \text{cost}(f_3) + \alpha_2(CT) = \beta^*(CT).$$

This completes the proof. □

The next lemma shows that if $f$ is an optimal non-canonical independent broadcast on a caterpillar $CT$ with no pair of adjacent trunks, with $\text{cost}(f) > 2(\text{diam}(CT) - 1)$, then there exists an optimal non-canonical independent broadcast $\bar{f}$ on $CT$ such that the $f$-values of the pendant neighbours of $v_0$ and $v_k$ only depend on the values of $\lambda_0, \lambda_1$ and $\lambda_{k-1}, \lambda_k$, respectively:

**Lemma 11** Let $CT = CT(\lambda_0, \ldots, \lambda_k)$ be a caterpillar of length $k \geq 1$, with no pair of adjacent trunks. If $f$ is an optimal non-canonical independent broadcast on $CT$ with $\text{cost}(f) > 2(\text{diam}(CT) - 1)$, then there exists an optimal non-canonical independent broadcast $\bar{f}$ on $CT$, thus with $\text{cost}(\bar{f}) = \text{cost}(f)$, such that, for every $i \in \{0, k\}$, we have
(a) From \( f_3 \) to \( f_4 \), pattern 02010201010, \( \text{cost}(f'_4) = \text{cost}(f'_3) + (3 - 1) + 0 \)

(b) From \( f_3 \) to \( f_4 \), pattern 2010201020, \( \text{cost}(f'_4) = \text{cost}(f'_3) + (2 - 1) + 1 \)

Figure 4: Proof of Lemma 10 from \( f_3 \) to \( f_4 \)
1. if $\lambda_1 = 1$ and $\lambda'_1 \geq 1$, then $\hat{f}(e_{1'}) = 2$,
2. if $\lambda_1 = 1$ and $\lambda'_1 = 0$, then $\hat{f}(e_{1'}) = 3$,
3. if $\lambda_i = 2$ and $\lambda'_i \geq 1$, then $\hat{f}(e_{1'}) = \hat{f}(e_{1}) = 1$,
4. if $\lambda_i = 2$ and $\lambda'_i = 0$, then $\hat{f}(e_{1'}) = 3$ and $\hat{f}(e_{1'}) = 0$,
5. if $\lambda_i \geq 3$, then $\hat{f}(e_{1'}) = 1$ for every $j$, $1 \leq j \leq \lambda_i$,

where $i' = 1$ if $i = 0$, or $i' = k - 1$ if $i = k$.

**Proof.** Note first that if such a broadcast $\hat{f}$ exists, then, by Lemma 6, $\hat{f}(u) = 0$ for every stem $u$ of $CT$. Therefore, the value of $\sum_{1 \leq j \leq \lambda_i} \hat{f}(e_{1'})$ cannot be strictly less than the value claimed in the lemma since otherwise it would contradict the optimality of $\hat{f}$.

By symmetry, it is enough to prove the lemma for the pendent neighbours of $v_0$. Let $CT_0 = CT(\lambda_0, \ldots, \lambda_k)$ be a minimal counterexample, with respect to the subgraph order, to the lemma. That is, every sub-caterpillar of $CT_0$ satisfies the statement of the lemma and, for every optimal non-canonical independent broadcast $f$ on $CT_0$ with $\text{cost}(f) > 2(\text{diam}(CT) - 1)$, there is a pendent neighbour, say $\ell_0^1$ without loss of generality, of $v_0$ such that $f(\ell_0^1) = x$ and $x$ is strictly greater than the value claimed by the lemma (note that, in case 3, if $f(\ell_0^1) = 2$ (resp. 0) and $f(\ell_0^2) = 0$ (resp. 2), then we can equivalently assign the value 1 to both of them). We will prove that such a minimal counterexample cannot exist.

Let $f_0$ be any such independent broadcast on $CT_0$ for which the value $f(\ell_0^1) = x$ is minimal. We thus have $x \geq 3$ whenever $\lambda_1 > 0$ or $\lambda_0 \geq 2$ (since in this latter case we can assign value 1 to each of the at least three pendent neighbours of $v_0$, and thus $x = 2$ would imply that $f_0$ is not optimal), and $x \geq 4$ whenever $\lambda_1 = 0$.

Since $f_0(\ell_0^1) = x > 1$, we have $f_0(v_i) = 0$ for every $i$, $1 \leq i \leq x - 2$, and $f_0(v_{x-1}) = 0$. Moreover, $x - 1 < k$ since $f_0$ is a non-canonical independent broadcast, and $v_{x-1}$ cannot be a trunk, since otherwise we could set $f_0(\ell_0^1) = x + 1$ (recall that, by Lemma 6, $f_0(v_i) = 0$ for every stem $v_i$, and thus $f_0(v_x) = 0$), contradicting the optimality of $f_0$.

Let now $CT_1 = (\lambda_{x-1}, \ldots, \lambda_k)$ be the caterpillar obtained from $CT_0$ by deleting vertices $v_0, \ldots, v_{x-2}$ and their pendent neighbours (see Figure 5(a)). Note that $f_0(u) = 0$ for every such deleted vertex $u \neq \ell_0^1$. Let $f_1$ denote the restriction of $f_0$ to $V(CT_1)$. Since $f_0(\ell_0^1) = x$, we get

$$f_1(u) = f_0(u) \leq \max\{e_{CT_1}(u), d_{CT_0}(u, \ell_0^1)\} \leq e_{CT_1}(u)$$

for every vertex $u \in V(CT_1)$, so that $f_1$ is an independent broadcast on $CT_1$ by Observation 4. Moreover, since $\text{diam}(CT_1) = \text{diam}(CT_0) - x + 1$, we have

$$\text{cost}(f_1) = \text{cost}(f_0) - x > 2(\text{diam}(CT_0) - 1) - x = 2(\text{diam}(CT_1) - 1) + x - 2.$$ 

Since $x > 1$, we thus have $\text{cost}(f_1) \geq 2(\text{diam}(CT_1) - 1)$. Therefore, since $CT_0$ is a minimal counterexample, we get that either $f_1$ is a canonical independent broadcast on $CT_1$ or there exists an optimal non-canonical independent broadcast $f'_1$ on $CT_1$ with $\text{cost}(f'_1) \geq \text{cost}(f_1)$ and $f'_1$ satisfies the statement of the lemma.

Suppose first that $f_1$ is a canonical independent broadcast. This implies

$$\text{cost}(f_1) = 2(\text{diam}(CT_1) - 1).$$

Hence,

$$\text{cost}(f_0) = \text{cost}(f_1) + x = 2(\text{diam}(CT_1) - 1) + x < 2(\text{diam}(CT_0) - 1),$$

which contradicts our assumption on $\text{cost}(f_0)$.

Therefore, there exists an optimal non-canonical independent broadcast $f'_1$ on $CT_1$ with $\text{cost}(f'_1) \geq \text{cost}(f_1)$ satisfying the statement of the lemma. If $\text{cost}(f'_1) > \text{cost}(f_1)$, the mapping $f_0'$ given by $f'_0(u) = f'_1(u)$ for every vertex $u \in V(CT_1)$ and $f'_0(u) = f_0(u)$ for every vertex
u ∈ V(CT_0) \ V(CT_1), is a non-canonical independent broadcast \( f'_0 \) on CT_0 (since \( x \geq 3 \)) that contradicts the optimality of \( f_0 \).

Hence, \( f_1 \) is optimal and thus satisfies the statement of the lemma. Let \( \hat{f}_1 \) be the non-canonical independent broadcast satisfying items 1 to 5 of the lemma, and let

\[
m = \max \{ \hat{f}_1(\ell^1_{x-1}), 1 \leq j \leq \lambda_{x-1} \}.
\]

We consider two cases, depending on whether \( v_{x-2} \) is a stem or not. Recall that \( v_{x-2} \neq v_0 \), since \( x \geq 3 \).

1. \( \lambda_{x-2} > 0 \).

Let \( f'_0 \) be the non-canonical independent broadcast on CT_0 given by \( f'_0(\ell^1_0) = x - 1 \), \( f'_0(\ell^1_{x-2}) = 2 \), \( f'_0(u) = 0 \) for every vertex \( u \in V(CT_0) \setminus (V(CT_1) \cup \{ \ell^1_0, \ell^1_{x-2} \}) \), and either \( f'_0(u) = \hat{f}_1(u) \) for every vertex \( u \in V(CT_1) \), if \( m \leq 2 \) (see Figure 5(b)), or \( f'_0(\ell^1_{x-1}) = 2 \) and \( f'_0(u) = \hat{f}_1(u) \) for every vertex \( u \in V(CT_0) \setminus \{ \ell^1_{x-1} \} \), if \( m = 3 \) (see Figure 5(c)). We then get \( \text{cost}(f'_0) = \text{cost}(f_0) + 1 \) if \( m \leq 2 \), contradicting the optimality of \( f_0 \), or \( \text{cost}(f'_0) = \text{cost}(f_0) \) if \( m = 3 \), in which case either \( f'_0 \) satisfies items 1 to 5 of the lemma or contradicts the minimality of \( x \).

2. \( \lambda_{x-2} = 0 \).

If \( x = 3 \), then \( \lambda_1 = 0 \) which implies \( x \geq 4 \), a contradiction. Hence, we have \( x \geq 4 \), and thus \( v_{x-3} \neq v_0 \). Let \( f'_0 \) be the non-canonical independent broadcast on CT_0 given by \( f'_0(\ell^1_0) = x - 2 \), \( f'_0(\ell^1_{x-3}) = 2 \), \( f'_0(u) = 0 \) for every vertex \( u \in V(CT_0) \setminus (V(CT_1) \cup \{ \ell^1_0, \ell^1_{x-3} \}) \), and \( f'_0(u) = \hat{f}_1(u) \) for every vertex \( u \in V(CT_1) \) (see Figure 5(d)). We then get \( \text{cost}(f'_0) = \text{cost}(f_0) \), and thus either \( f'_0 \) satisfies items 1 to 5 of the lemma or contradicts the minimality of \( x \).

This concludes the proof.

We now consider the internal stems of a caterpillar. Recall that, by Lemma 6, \( \hat{f}(v_i) = 0 \) for every internal stem \( v_i \) of CT, \( 1 \leq i \leq k - 1 \). The next lemma shows that if \( f \) is an optimal non-canonical independent broadcast on a caterpillar CT with no pair of adjacent trunks, with \( \text{cost}(f) > 2(\text{diam}(CT) - 1) \), then there exists an optimal non-canonical independent broadcast \( \hat{f} \) on CT such that \( \hat{f}^*(v_i) - \hat{f}(v_i) = \hat{f}^*(v_i) > 0 \) for every internal stem \( v_i \) of CT, \( 1 \leq i \leq k - 1 \).

**Lemma 12** Let CT = CT(\( \lambda_0, \ldots, \lambda_k \)) be a caterpillar of length \( k \geq 1 \), with no pair of adjacent trunks. If \( f \) is an optimal non-canonical independent broadcast on CT with \( \text{cost}(f) > 2(\text{diam}(CT) - 1) \), then there exists an optimal non-canonical independent broadcast \( \hat{f} \) on CT, thus with \( \text{cost}(\hat{f}) = \text{cost}(f) \), such that:

1. \( \hat{f} \) satisfies the five items of Lemma 11

2. for every \( i, 1 \leq i \leq k - 1 \), if \( \lambda_i > 0 \), then \( \hat{f}^*(v_i) > 0 \).

**Proof.** We know by Lemma 11 that there exists an optimal non-canonical independent broadcast \( \hat{f} \) on CT, with \( \text{cost}(\hat{f}) = \text{cost}(f) \), satisfying the five items of Lemma 11. Moreover, one suppose that \( \hat{f} \) has been chosen in such a way that \( V_f^+ \) contains the largest possible number of pendent vertices.

Suppose to the contrary that there exists a vertex \( v_i, 1 \leq i \leq k - 1 \), with \( \lambda_i > 0 \) and \( \hat{f}^*(v_i) = 0 \), and that for every \( j < i \), \( \hat{f}^*(v_j) > 0 \) whenever \( \lambda_j > 0 \). We consider three cases.

1. \( i = 1 \) or \( i = k - 1 \).

By symmetry, it suffices to consider the case \( i = 1 \). By Lemma 11, we know that \( \hat{f}(\ell^1_0) \leq 2 \) for every \( j, 1 \leq j \leq \lambda_0 \). Therefore, no pendent neighbour of \( v_1 \) is \( \hat{f} \)-dominated by a pendent neighbour of \( v_0 \). Let \( y \) be the vertex of CT that \( \hat{f} \)-dominates the pendent neighbours of
(a) The sub-caterpillar \( CT_1 \)

(b) \( \lambda_{x-2} > 0 \) and \( m \leq 2 \)

(c) \( \lambda_{x-2} > 0 \) and \( m = 3 \)

(d) \( \lambda_{x-2} = 0 \)

Figure 5: Configurations for the proof of Lemma 11
we have at least two such vertices $v$ and $y$ by 2. Let $y$ be the (unique) vertex of $CT$ that $\tilde{f}$-dominates the $g$-broadcast vertices with $g(x') = 1$ (note that since every such $x'$ was $\tilde{f}$-dominated by $y$, we have $g(z) = \tilde{f}(z) = 0$ for every neighbour $z$ of $x'$).

Now, if there exists a vertex $z$ which is $\tilde{f}$-dominated only by $y$, we get $\cost(g) \geq \cost(\tilde{f}) + 1$, contradicting the optimality of $\tilde{f}$. If no such vertex exists, we get $\cost(g) = \cost(\tilde{f})$ and $V_g$ contains more pendent vertices than $V_{\tilde{f}}$, contrary to our assumption.

2. $i = 2$ and $\lambda_1 = 0$, or $i = k - 2$ and $\lambda_{k-1} = 0$.

By symmetry, it suffices to consider the case $i = 2$. By Lemma 11, we know that $\tilde{f}(\ell_0^i) \leq 3$ for every $j$, $1 \leq j \leq \lambda_0$. Therefore, no pendent neighbour of $v_2$ is $\tilde{f}$-dominated by a pendent neighbour of $v_0$. Let $y$ be the (unique) vertex of $CT$ that $\tilde{f}$-dominates the $y$-dominated neighbours of $v_2$ (note that we necessarily have $\tilde{f}(y) \geq 2$).

If $y = v_3$ and $\tilde{f}(v_3) = 3$ (since $\tilde{f}^*(v_0) > 0$, we necessarily have $\tilde{f}(v_3) \leq 3$), we define the mapping $g$ as follows. For every vertex $u$ of $CT$, let

$$g(u) = \begin{cases} 
0 & \text{if } u = v_3, \\
3 & \text{if } u = \ell_2^i, \\
1 & \text{if } u \neq \ell_2^i, u \text{ is } \tilde{f}\text{-dominated only by } v_3 \text{ and } d_{CT}(u, y) = 2, \\
\tilde{f}(u) & \text{otherwise.}
\end{cases}$$

Otherwise (including the case $y = v_3$ and $\tilde{f}(v_3) = 2$), the mapping $g$ is defined by

$$g(u) = \begin{cases} 
\tilde{f}(y) - 2 & \text{if } u = y, \\
2 & \text{if } u = \ell_2^1, \\
1 & \text{if } u \neq \ell_2^1, u \text{ is } \tilde{f}\text{-dominated only by } y \text{ and } d_{CT}(u, y) = \tilde{f}(y) - 1, \\
\tilde{f}(u) & \text{otherwise,}
\end{cases}$$

for every vertex $u$ of $CT$.

In both cases, the mapping $g$ is again a non-canonical independent broadcast on $CT$ with $\cost(g) \geq \cost(\tilde{f})$. Indeed, all vertices $x$ with $d_{CT}(x, y) < \tilde{f}(y) - 1$ that were $\tilde{f}$-dominated by $y$ are $g$-dominated by $\ell_2^1$ (if $y = v_3$) or still $g$-dominated by $y$ (if $y \neq v_3$), and all vertices $x' \neq \ell_2^1$ with $\tilde{f}(y) - 1 \leq d_{CT}(x', y) \leq \tilde{f}(y)$ that were $\tilde{f}$-dominated only by $y$ are now either $g$-broadcast vertices (if $d_{CT}(x', y) = \tilde{f}(y) - 1$) or $g$-dominated by a vertex $x''$ with $d_{CT}(x'', y) = \tilde{f}(y) - 1$ and $g(x'') = 1$.

We then get a contradiction as in Case 1.

3. $2 < i < k - 2$, or $i = 2$ and $\lambda_1 > 0$, or $i = k - 2$ and $\lambda_{k-1} > 0$.

In this case, we have $\tilde{f}^*(v_j) > 0$ for every vertex $v_j$ with $j < i$ and $\lambda_j > 0$. Note also that we have at least two such vertices $v_j$ with $j < i$ and $\lambda_j > 0$.

By symmetry, it suffices to consider the cases $2 < i < k - 2$, and $i = 2$ (with $\lambda_1 > 0$). We consider three subcases.

(a) Suppose first that the pendent neighbours of $v_i$ are $\tilde{f}$-dominated only by a vertex $y = v_{j_0}$ or $y = \ell_{j_0}^k$ with $j_0 < i$ and $1 \leq k_0 \leq \lambda_{j_0}$. Observe that the pendent neighbours
of $v_i$ cannot be $\tilde{f}$-dominated by two such vertices, say $y$ and $y'$, since we would have $d_{CT}(y, y') < d_{CT}(y, \ell_i^1)$ so that $\tilde{f}$ would not be independent. Since $\tilde{f}^*(v_j) > 0$ for every $j < i$ such that $\lambda_j > 0$, we necessarily have, by Lemma 6, either $y$ is a pendent neighbour of $v_{i-1}$, if $\lambda_{i-1} > 1$, or a pendent neighbour of $v_{i-2}$, if $\lambda_{i-1} = 0$. Moreover, since $\tilde{f}^*(v_j) > 0$ for every $j < i$ such that $\lambda_j > 0$, and since we have at least two such vertices, we necessarily have $\tilde{f}(y) \leq 3$. This implies in particular $\lambda_{i-1} > 0$, as otherwise we would have $\tilde{f}(y) \leq 3$ and $d_{CT}(y, \ell_i^1) = 4$, contradicting the fact that $y$ $\tilde{f}$-dominates $\ell_i^1$, and thus $y$ is a pendent neighbour of $v_{i-1}$.

Let now $g$ be the mapping defined as follows. For every vertex $u$ of $CT$, let

$$g(u) = \begin{cases} \tilde{f}(y) - 1 & \text{if } u = y, \\ 1 & \text{if } u = \ell_i^1, \\ 1 & \text{if } u \neq \ell_i^1, u \text{ is } \tilde{f}\text{-dominated only by } y \text{ and } d_{CT}(u, y) = \tilde{f}(y), \\ \tilde{f}(u) & \text{otherwise}. \end{cases}$$

Again, the mapping $g$ is a non-canonical independent broadcast on $CT$ with $\text{cost}(g) \geq \text{cost}(\tilde{f})$. Indeed, all vertices $x$ with $d_{CT}(x, y) < \tilde{f}(y)$ that were $\tilde{f}$-dominated by $y$ are still $g$-dominated either by $y$, and all vertices $x' \neq \ell_i^1$ with $d_{CT}(x', y) = \tilde{f}(y)$ that were $\tilde{f}$-dominated only by $y$ are now $g$-broadcast vertices.

We then get a contradiction as in Cases 1 and 2.

(b) Suppose now that the pendent neighbours of $v_i$ are $\tilde{f}$-dominated only by a vertex $y = v_{j_0}$ (with $\lambda_{j_0} = 0$) or $y = \ell_{k_0}$ (1 $\leq k_0 \leq \lambda_{j_0}$), with $j_0 > i$. Observe that, using the same argument as in Case (a), such a vertex $y$ must be unique. Moreover, we necessarily have $\tilde{f}(y) \geq 2$.

If $\lambda_{i-1} = 0$, we consider two cases, as we did in Case 2. If $y = v_{i+1}$ and $\tilde{f}(v_{i+1}) = 3$, we define the mapping $g$ by

$$g(u) = \begin{cases} 0 & \text{if } u = v_{i+1}, \\ 3 & \text{if } u = \ell_i^1, \\ 1 & \text{if } u \neq \ell_i^1, u \text{ is } \tilde{f}\text{-dominated only by } y \text{ and } d_{CT}(u, y) = 2, \\ \tilde{f}(u) & \text{otherwise}, \end{cases}$$

for every vertex $u$ of $CT$. Otherwise, the mapping $g$ is defined by

$$g(u) = \begin{cases} \tilde{f}(y) - 2 & \text{if } u = y, \\ 2 & \text{if } u = \ell_i^1, \\ 1 & \text{if } u \neq \ell_i^1, u \text{ is } \tilde{f}\text{-dominated only by } y \text{ and } d_{CT}(u, y) = \tilde{f}(y) - 1, \\ \tilde{f}(u) & \text{otherwise}, \end{cases}$$

for every vertex $u$ of $CT$.

Otherwise, that is, $\lambda_{i-1} > 0$, we define the mapping $g$ as follows. For every vertex $u$ of $CT$, let

$$g(u) = \begin{cases} \tilde{f}(y) - 1 & \text{if } u = y, \\ 1 & \text{if } u = \ell_i^1, \\ 1 & \text{if } u \neq \ell_i^1, u \text{ is } \tilde{f}\text{-dominated only by } y \text{ and } d_{CT}(u, y) = \tilde{f}(y), \\ \tilde{f}(u) & \text{otherwise}. \end{cases}$$

Again, using similar arguments, in each case the above-defined mapping is a non-canonical independent broadcast on $CT$ with $\text{cost}(g) \geq \text{cost}(\tilde{f})$ and the contradiction arises as in Cases 1 and 2.

(c) Suppose finally that the pendent neighbours of $v_i$ are $\tilde{f}$-dominated both by a vertex $y_1 = v_{j_1}$ or $y_1 = \ell_{k_1}^{j_1}$ with $j_1 < i$ and $1 \leq k_1 \leq \lambda_{j_1}$, and by a vertex $y_2 = v_{j_2}$ or $y_2 = \ell_{k_2}^{j_2}$ with $j_2 > i$ and $1 \leq k_2 \leq \lambda_{j_2}$ (again, both $y_1$ and $y_2$ must be unique). In that case, as
discussed in Case (a) above, we necessarily have $\lambda_{i-1} > 0$. Moreover, we necessarily have $\tilde{f}(y_1) = 3$ and $\tilde{f}(y_2) \geq 2$.

Let now $g$ be the mapping defined as follows. For every vertex $u$ of $CT$, let

$$g(u) = \begin{cases} 
\tilde{f}(y_1) - 1 & \text{if } u = y_1, \\
\tilde{f}(y_2) - 1 & \text{if } u = y_2, \\
2 & \text{if } u = \ell_i^1, \\
1 & \text{if } u \neq \ell_i^1, \text{ } u \text{ is } \tilde{f}\text{-dominated only by } y_2 \text{ and } d_{CT}(u, y_2) = \tilde{f}(y_2), \\
\tilde{f}(u) & \text{otherwise.}
\end{cases}$$

Note here that no vertex at distance $\tilde{f}(y_1)$ from $y_1$ can be $\tilde{f}$-dominated only by $y_1$. Indeed, suppose that such a vertex, say $w$, exists. Clearly, $w$ cannot be “to the left of $v_i$” since this would imply $w = v_{i-3}$ and $\lambda_{i-2} = 0$, but in that case $w$ is also $\tilde{f}$-dominated by at least one of its pendant neighbours. On the other hand, $w$ cannot be “to the right of $v_i$” since in that case $w$ would also be $\tilde{f}$-dominated by $y_2$.

Again, using similar arguments, the above-defined mapping is a non-canonical independent broadcast on $CT$ with cost$(g) \geq \text{cost}(\tilde{f})$ and the contradiction arises as in Cases 1 and 2.

We thus get a contradiction in each case. This completes the proof. \hfill \square

Our aim now is to prove that if $f$ is an optimal non-canonical independent broadcast on a caterpillar $CT$ with no pair of adjacent trunks, with cost$(f) > 2(\text{diam}(CT) - 1)$, then cost$(f) = \text{cost}(\beta^*)$ (Lemma \ref{lemma:16} below). We first prove that for every such broadcast $f$, $f(v_i) \leq 1$ for every trunk $v_i$. This easily follows from Lemma \ref{lemma:12}

**Lemma 13** Let $CT = CT(\lambda_0, \ldots, \lambda_k)$ be a caterpillar of length $k \geq 1$, with no pair of adjacent trunks. If $f$ is an optimal non-canonical independent broadcast on $CT$ with cost$(f) > 2(\text{diam}(CT) - 1)$, then there exists an optimal non-canonical independent broadcast $\tilde{f}$ on $CT$, thus with cost$(\tilde{f}) = \text{cost}(f)$, such that:

1. $\tilde{f}$ satisfies the two items of Lemma \ref{lemma:12}

2. for every $i$, $1 \leq i \leq k - 1$, if $\lambda_i = 0$, then $\tilde{f}^*(v_i) \leq 1$.

**Proof.** We know by Lemma \ref{lemma:12} that there exists an optimal non-canonical independent broadcast $\tilde{f}$ on $CT$ satisfying the two items of Lemma \ref{lemma:12} so that, in particular, $\tilde{f}^*(v_j) > 0$ for every stem $v_j$, $0 \leq j \leq k$. Since $CT$ has no pair of adjacent trunks, and $\tilde{f}$ is independent, we thus necessarily have $\tilde{f}^*(v_i) \leq 1$ for every trunk $v_i$, $1 \leq i \leq k - 1$. \hfill \square

Finally, the next lemma will show that the cost of any optimal non-canonical independent broadcast on a caterpillar $CT$ of length $k \geq 1$ with no pair of adjacent trunks cannot exceed the value $\beta^*(CT)$.

We first introduce more notation. Let $CT$ be a caterpillar of length $k \geq 1$, with no pair of adjacent trunks. We denote by $\sigma$ a sequence of $\ell$ consecutive spine vertices in $CT$, that is, $\sigma = v_i \ldots v_{i+\ell-1}$, with $\ell \leq k+1$ and $0 \leq i \leq k-\ell+1$. For such a given sequence $\sigma = v_i \ldots v_{i+\ell-1}$, we denote by $t_\sigma$ the number of trunks in $\sigma$, that is,

$$t_\sigma = |\{v_j \mid i \leq j \leq i + \ell - 1 \text{ and } \lambda_j = 0\}|.$$

If $f$ is an independent broadcast on $CT$, we then denote by $f^*(\sigma)$ the weight of $\sigma$, that is,

$$f^*(\sigma) = \sum_{0 \leq j \leq \ell-1} f^*(v_{i+j}).$$
Lemma 14 Let \( CT = CT(\lambda_0, \ldots, \lambda_k) \) be a caterpillar of length \( k \geq 1 \), with no pair of adjacent trunks, and \( f \) be an optimal non-canonical independent broadcast on \( CT \) with \( \text{cost}(f) > 2(\text{diam}(CT) - 1) \). Then there exists an optimal non-canonical independent broadcast \( \tilde{f} \) on \( CT \), thus with \( \text{cost}(\tilde{f}) = \text{cost}(f) \), such that:

1. \( \tilde{f} \) satisfies the two items of Lemma 13.
2. For every \( i, 0 \leq i \leq k \), if \( \lambda_i \geq 3 \), then \( \tilde{f}^*(v_i) \leq \lambda_i \).
3. If \( v_a v_{i+1}, 0 \leq a < k \), is an occurrence of the pattern \( 1^+2^- \) (resp. of the pattern \( 2^--1^+ \)), then \( \tilde{f}^*(v_{i+1}) \leq 2 \) (resp. \( \tilde{f}^*(v_a) \leq 2 \)).
4. If \( v_a \sigma v_b \) is an occurrence of the pattern \( 1^+2^-(02^-)^+1^+ \), then \( \tilde{f}^*(\sigma) \leq 3t_{\sigma} + 2 \) if \( v_a \sigma v_b \) is an occurrence of the pattern \( 1^+2(02^-)^+1^+ \), and \( \tilde{f}^*(\sigma) \leq 3t_{\sigma} + 1 \) otherwise.
5. If \( \sigma \) is an occurrence of the pattern \( 02^-(02^-)^r0 \), then \( \tilde{f}^*(\sigma) \leq 3t_{\sigma} - 2 \) if \( v_a \sigma v_b \) is an occurrence of the pattern \( 02(02^-)^r0 \), and \( \tilde{f}^*(\sigma) \leq 3t_{\sigma} - 3 \) otherwise.
6. If \( \sigma \) is an occurrence of the pattern \( [2^--(02^-)^r0 \text{ or of the pattern } 02^-(02^-)^r] \), then \( \tilde{f}^*(\sigma) \leq 3t_{\sigma} \).

Proof. We consider the six items of the lemma.

1. We know by Lemma 13 that there exists an optimal non-canonical independent broadcast \( \tilde{f} \) on \( CT \) satisfying the two items of Lemma 13 so that, in particular, \( \tilde{f}^*(v_i) > 0 \) for every stem \( v_i, 0 \leq i \leq k \) and \( \tilde{f}^*(v_j) \leq 1 \) for every trunk \( v_j, 1 \leq j \leq k - 1 \). We thus assume for all following items that such an optimal non-canonical independent broadcast \( \tilde{f} \) on \( CT \) has been chosen.

2. Suppose to the contrary that there exists some \( i, 0 \leq i \leq k \), with \( \tilde{f}^*(v_i) > \lambda_i \geq 3 \). This implies that \( v_i \) has exactly one pendant neighbour, say \( \ell_1^i \) without loss of generality, which is an \( \tilde{f} \)-broadcast vertex. Since \( \tilde{f}(\ell_1^i) \geq 4 \), we necessarily have a stem \( v \) with \( d_{CT}(v_i, v) \leq 2 \) and \( \tilde{f}^*(v) = 0 \), contradicting our assumption that \( \tilde{f} \) satisfies Lemma 12.

3. Let \( v_a v_{i+1}, 0 \leq a < k \), be an occurrence of the pattern \( 1^+2^- \) (the case \( 2^--1^+ \) is similar, by symmetry). By Lemmas 6 and 12 we know that \( \tilde{f}^*(v_a) > 0 \) and \( \tilde{f}(v_a) = 0 \). This clearly implies \( \tilde{f}^*(v_{i+1}) \leq 2 \).

4. Let \( v_a \sigma v_b = v_i v_{i+1} \ldots v_{i+2r+2} \) be an occurrence of the pattern \( 1^+2(02^-)^+1^+ \), for some \( i, 0 \leq i \leq k - 2r - 2 \). We thus have \( t_{\sigma} = r \). Since \( \tilde{f} \) satisfies Lemma 13 we have \( \tilde{f}^*(v_i) > 0 \), \( \tilde{f}^*(v_{i+2r+2}) > 0 \), \( \tilde{f}^*(v_{i+2r+1}) > 0 \) for every \( j, 0 \leq j \leq r \), and \( \tilde{f}^*(v_{i+2j}) \leq 1 \) for every \( j, 1 \leq j \leq r \). This implies

\[
\tilde{f}^*(v_{i+1}) \leq 2, \quad \tilde{f}^*(v_{i+2r+1}) \leq 2, \quad \text{and} \quad \tilde{f}^*(v_{i+2r+1}) \leq 3 \quad \text{for every} \quad j, 1 \leq j \leq r - 1. 
\]

We consider three subcases, according to the number of trunks in \( \sigma \) that are broadcast vertices.

(a) \( \tilde{f}(v_{i+2j}) = 1 \) for every \( j, 1 \leq j \leq r \).

In that case, every pendant vertex in \( \sigma \) is an \( \tilde{f} \)-broadcast vertex, with \( \tilde{f} \)-value 1. This gives

\[
\tilde{f}^*(\sigma) = \lambda(\sigma) + \tau(\sigma) \leq 2(r + 1) + r = 3r + 2 = 3t_{\sigma} + 2,
\]

if \( v_a \sigma v_b \) is an occurrence of the pattern \( 1^+2(02^-)^+1^+ \), and

\[
\tilde{f}^*(\sigma) = \lambda(\sigma) + \tau(\sigma) \leq 1 + 2r + r = 3r + 1 = 3t_{\sigma} + 1,
\]

otherwise (since we have at least one stem in \( \sigma \) with \( \tilde{f} \)-value 1).

(b) \( \tilde{f}(v_{i+2j}) = 0 \) for every \( j, 1 \leq j \leq r \).

In that case, by \([\text{1}]\), we get

\[
\tilde{f}^*(\sigma) \leq 2 + 3(r - 1) + 2 = 3r + 1 = 3t_{\sigma} + 1.
\]
(c) Not all trunks in $\sigma$ have the same $\tilde{f}$-value.
Suppose that $\tilde{f}$ has been chosen in such a way that the number of trunks in $\sigma$ with $\tilde{f}$-value 0 is maximal. In that case, $\sigma$ contains two consecutive trunks, say $v_{i+2j_0}$ and $v_{i+2j_0+2}$, $1 \leq j_0 \leq r - 1$, with $\tilde{f}(v_{i+2j_0}) = 0$ and $\tilde{f}(v_{i+2j_0+2}) = 1$, without loss of generality (by symmetry). This implies $\tilde{f}^*(v_{i+2j_0+1}) = \lambda_{i+2j_0+1} \leq 2$. We can then modify $\tilde{f}$ by setting $\check{f}(v_{i+2j_0}) = \tilde{f}(v_{i+2j_0+2}) = 0$, $\check{f}(\ell_{i+2j_0+1}) = 3$ (and $\check{f}(\ell^2_{i+2j_0+1}) = 0$ if $\lambda_{i+2j_0+1} = 2$), contradicting our assumption on the maximality of the number of trunks with $\check{f}$-value 0. Therefore, this case cannot occur and we are done.

5. The proof uses the same ideas as the proof of the previous case. Let $\sigma = v_{i_1}v_{i_2} \ldots v_{i_k}v_{i_k+2}$ be an occurrence of the pattern $02^-(02^-)^r0$, for some $i$, $1 \leq i \leq k - 2r - 3$. We thus have $t_\sigma = r + 2$. Since $\tilde{f}$ satisfies Lemma 13, we have

\begin{equation}
0 < \check{f}^*(v_{i_j+2j+1}) \leq 3 \quad \text{for every } j, \quad 0 \leq j \leq r,
\end{equation}

and

\begin{equation}
\check{f}^*(v_{i_j+2j}) \leq 1 \quad \text{for every } j, \quad 0 \leq j \leq r + 1.
\end{equation}

We consider three subcases, according to the number of trunks in $\sigma$ that are broadcast vertices.

(a) $\check{f}(v_{i+2j}) = 1$ for every $j$, $0 \leq j \leq r + 1$.

In that case, every pendant vertex in $\sigma$ is an $\check{f}$-broadcast vertex, with $\check{f}$-value 1. This gives

\begin{equation}
\check{f}^*(\sigma) = \lambda(\sigma) + \tau(\sigma) \leq 2(r + 1) + r + 2 = 3r + 4 = 3t_\sigma - 2,
\end{equation}

if $\sigma$ is an occurrence of the pattern $02^-(02^-)^r0$, and

\begin{equation}
\check{f}^*(\sigma) = \lambda(\sigma) + \tau(\sigma) \leq 1 + 2r + r + 2 = 3r + 3 = 3t_\sigma - 3,
\end{equation}

otherwise (since we have at least one stem in $\sigma$ with $\check{f}$-value 1).

(b) $\check{f}(v_{i+2j}) = 0$ for every $j$, $0 \leq j \leq r + 1$.

In that case, by (2) and (3), we get

\begin{equation}
\check{f}^*(\sigma) \leq 3(r + 1) = 3r + 3 = 3t_\sigma - 3.
\end{equation}

(c) Not all trunks in $\sigma$ have the same $\check{f}$-value.

Suppose that $\check{f}$ has been chosen in such a way that the number of trunks in $\sigma$ with $\check{f}$-value 0 is maximal. In that case, $\sigma$ contains two consecutive trunks, say $v_{i+2j_0}$ and $v_{i+2j_0+2}$, $0 \leq j_0 \leq r$, with $\check{f}(v_{i+2j_0}) = 0$ and $\check{f}(v_{i+2j_0+2}) = 1$, without loss of generality (by symmetry). This implies $\check{f}^*(v_{i+2j_0+1}) = \lambda_{i+2j_0+1} \leq 2$. We can then modify $\check{f}$ by setting $\check{f}(v_{i+2j_0}) = \check{f}(v_{i+2j_0+2}) = 0$, $\check{f}(\ell^1_{i+2j_0+1}) = 3$ (and $\check{f}(\ell^2_{i+2j_0+1}) = 0$ if $\lambda_{i+2j_0+1} = 2$), contradicting our assumption on the maximality of the number of trunks with $\check{f}$-value 0. Therefore, this case cannot occur and we are done.

6. Let $v_0 \ldots v_{2r+1}$ be an occurrence of the pattern $2^-((02^-)^r0$ (the case $02^-(02^-)^r$ is similar, by symmetry). We first prove that for every $i$, $0 \leq i \leq r$, $\check{f}^*(v_{2i}) + \check{f}^*(v_{2i+1}) \leq 3$. By Lemma 13, we know that $\check{f}(v_{2i+1}) \leq 1$. If $\check{f}(v_{2i+1}) = 1$, then we have $\check{f}(\ell^1_{2i}) \leq 1$ for every pendant neighbour $\ell^1_{2i}$ of $v_{2i}$, and thus $\check{f}^*(v_{2i}) \leq \lambda_{2i} \leq 2$. On the other hand, if $\check{f}(v_{2i+1}) = 0$, we have $\check{f}^*(v_{2i}) \leq 3$ (which implies $\check{f}(\ell^1_{2i}) = 3$ for a pendant neighbour $\ell^1_{2i}$ of $v_{2i}$) since otherwise we would have $\check{f}^*(v_{2i+2}) = 0$, contradicting Lemma 12. In both cases, we thus get the desired inequality.

Since $\sigma$ contains exactly $r + 1 = t_\sigma$ distinct pairs of vertices of the form $(v_{2i}, v_{2i+1})$, we get

\begin{equation}
\check{f}^*(\sigma) = \sum_{i=0}^{i=r} (\check{f}^*(v_{2i}) + \check{f}^*(v_{2i+1})) \leq 3(r + 1) = 3t_\sigma.
\end{equation}
This completes the proof. \hfill \Box

The following lemma states that Lemma 14 covers all possible caterpillars that admit a non-canonical independent broadcast with sufficiently large cost.

**Lemma 15** If $CT = CT(\lambda_0, \ldots, \lambda_k)$ is a caterpillar of length $k \geq 1$, with no pair of adjacent trunks, such that there exists an optimal non-canonical independent broadcast $f$ on $CT$ with $\text{cost}(f) > 2(\text{diam}(CT) - 1)$, then Lemma 14 gives an upper bound on $\text{cost}(f)$.

**Proof.** Let $CT = CT(\lambda_0, \ldots, \lambda_k)$ be a caterpillar of length $k \geq 1$, with no pair of adjacent trunks, $f$ be an optimal non-canonical independent broadcast on $CT$ with $\text{cost}(f) > 2(\text{diam}(CT) - 1)$, and $v_i, 0 \leq i \leq k$, a spine vertex of $CT$.

If $\lambda_i \geq 3$, then $f^*(v_i) = \lambda_i$ by item 5 of Lemma 11 and thus by item 1 of Lemma 14.

If $\lambda_i = 0$, then $f^*(v_i) \leq 1$ by item 2 of Lemma 13 and thus by item 1 of Lemma 14.

Suppose now that $1 \leq \lambda_i \leq 2$. If $i = 0$ or $i = k$, then $f^*(v_i) \leq 3$ by items 1 to 4 of Lemma 11 and thus by item 1 of Lemma 14. We assume now that $1 \leq i \leq k - 1$. If $\lambda_{i-1} > 0$ or $\lambda_{i+1} > 0$, then $f^*(v_i) \leq 2$ by item 3 of Lemma 14.

The remaining case is thus $1 \leq i \leq k - 1$, $\lambda_{i-1} = 0$ and $\lambda_{i+1} = 0$. We consider the set of all occurrences of a pattern, in which 0’s and 2’s alternate, that contain vertices $v_{i-1}$, $v_i$ and $v_{i+1}$. Let $\sigma = v_{i-1}v_{i+1} \ldots v_b, 0 \leq a < i - 1 < i + 1 < b \leq k$ be such an occurrence with maximal length. Note here that we necessarily have $v_a \neq v_i$ and $v_b \neq v_i$. We consider three cases.

1. $\lambda_a = \lambda_b = 0$.

   By the maximality of $\sigma$, we necessarily have $\lambda_{a-1} \geq 3$ and $\lambda_{b+1} \geq 3$. Therefore, the value of $f^*(\sigma)$ is bounded by item 5 of Lemma 14.

2. $\lambda_a = 0$ and $\lambda_b > 0$ (the case $\lambda_a > 0$ and $\lambda_b = 0$ is similar, by symmetry).

   By the maximality of $\sigma$, we necessarily have $\lambda_{a-1} \geq 3$ and either $b = k$, or $b < k$ and $\lambda_{b+1} \geq 1$. If $b = k$, then the value of $f^*(\sigma)$ is bounded by item 6 of Lemma 14. If $b < k$ and $\lambda_{b+1} \geq 1$, then $f^*(v_a \ldots v_{b-1})$ is bounded by item 5 of Lemma 14.

3. $\lambda_a > 0$ and $\lambda_b > 0$.

   By the maximality of $\sigma$, we necessarily have (i) either $a = 0$, or $a > 0$ and $\lambda_{a-1} \geq 1$, and (ii) either $b = k$, or $b < k$ and $\lambda_{b+1} \geq 1$.

   If $a > 0$ and $b < k$, then the value of $f^*(\sigma)$ is bounded by item 4 of Lemma 14.

   If $a = 0$ and $b < k$ (the case $a > 0$ and $b = k$ is similar, by symmetry), then the value of $f^*(v_a \ldots v_{b-1})$ is bounded by item 6 of Lemma 14.

Finally, if $a = 0$ and $b = k$, the caterpillar $CT$ has pattern $2^-(02^-)^+$. In that case, we have $\text{diam}(CT) = 2r + 2$ and thus $2(\text{diam}(CT) - 1) = 4r + 2$. By Lemmas 12 and 13 (as discussed in the proof of item 6 of Lemma 14), we have $f^*(v_j) + f^*(v_{j+1}) \leq 3$ for every $j, 0 \leq j \leq 2r - 2$. Moreover, by item 2 of Lemma 11, we have $f^*(v_{2r}) = 3$. Therefore, $f^*(CT) \leq 3r + 3 \leq 4r + 2 = 2(\text{diam}(CT) - 1)$. This contradicts our assumption on the value of $\text{cost}(f)$, and thus this case cannot occur.

Therefore, in all cases, either $f^*(v_i)$ or $f^*(\sigma)$ for an occurrence $\sigma$ of a pattern containing $v_i$ is bounded by some item of Lemma 14. This concludes the proof. \hfill \Box

Using Lemmas 14 and 15, we can now prove that no optimal non-canonical independent broadcast $f$ on $CT$ with $\text{cost}(f) > 2(\text{diam}(CT) - 1)$ and $\text{cost}(f) > \beta^*(CT)$ exists.

**Lemma 16** Let $CT = CT(\lambda_0, \ldots, \lambda_k)$ be a caterpillar of length $k \geq 1$, with no pair of adjacent trunks, and $f$ be an optimal non-canonical independent broadcast on $CT$ with $\text{cost}(f) > 2(\text{diam}(CT) - 1)$. We then have $\text{cost}(f) \leq \beta^*(CT)$. 

19
Proof. Let us denote by $f_4$ the non-canonical independent broadcast on $CT$ constructed in the proof of Lemma 10, thus with $\text{cost}(f_4) = \beta^*(CT)$. By considering the four steps involved in the construction of $f_4$, it clearly appears that $f_4$ satisfies the five items of Lemma 11. Indeed, the $f_4$-value of $v_i$ is set to 1 in step 1 of Lemma 10 and is not modified in steps 2 to 4. Therefore, we get $f_4^*(v_i) = f_4^*(v_i) = \lambda_i$ for every such $v_i$.

1. **Item 2 of Lemma 14**
   If $v_i$ is a stem with $\lambda_i \geq 3$, the value of its pendant neighbours is not modified in steps 2 to 4. Therefore, we get $f_4^*(v_i) = f_4^*(v_i) = \lambda_i$ for every such $v_i$.

2. **Item 3 of Lemma 14**
   Let $v_0v_{a+1}$, $0 \leq a < k$, be an occurrence of the pattern $1^+2^-$ (the case $2^-1^+$ is similar, by symmetry). Note here that if $v_{a+1}$ is the leftmost vertex of an occurrence of the pattern $1^+2^+(02)^+1^+$, then the value of its pendant neighbours is not modified in step 3.
   Suppose now that $\lambda_{a+1} = 1$, then, in step 2, the value of $f_4^*(v_{a+1})$ is set to 2 and not modified in step 4. If $\lambda_{a+1} = 2$, then the value of the pendent neighbours of $v_{a+1}$ is not modified in steps 2 and 4. Therefore, $f_4^*(v_{a+1}) = 2$ in both cases.

3. **Item 4 of Lemma 14**
   Let $v_0\sigma v_b = v_0v_{i+1}\ldots v_{i+2r+2}$ be an occurrence of the pattern $1^+2^-(02)^+r1^+$, for some $i$, $0 \leq i \leq k - 2r - 2$. In that case, we have $t_\sigma = r$.
   If $v_0\sigma v_b$ is an occurrence of the pattern $1^+2^+(02)^+r1^+$, the value of the vertices of $\sigma$ are not modified in steps 2 to 4. Therefore, we have $f_4^*(\sigma) = f_4^*(\sigma) = 2r + 2 = 3t_\sigma + 2$.
   Suppose now that $\sigma$ contains at least one stem having only one pendant neighbour. In step 3, the value of $f_4^*(\sigma)$ is set to 2 if $\lambda_{i+1} = 1$, the value of $f_4^*(\sigma)$ is set to 2 if $\lambda_{i+1} = 1$, the value of $f_4^*(\sigma)$ is set to 2 if $\lambda_{i+1} = 1$, the value of $f_4^*(\sigma)$ is set to 2 if $\lambda_{i+1} = 1$, the value of $f_4^*(\sigma)$ is set to 2 if $\lambda_{i+1} = 1$, the value of $f_4^*(\sigma)$ is set to 2 if $\lambda_{i+1} = 1$, the value of $f_4^*(\sigma)$ is set to 2 if $\lambda_{i+1} = 1$, the value of $f_4^*(\sigma)$ is set to 2 if $\lambda_{i+1} = 1$, the value of $f_4^*(\sigma)$ is set to 2 if $\lambda_{i+1} = 1$. Therefore, the value of every trunk is set to 0. We thus get $f_4^*(\sigma) = f_4^*(\sigma) = 2 + 2 + 3(r - 1) = 3r + 1 = 3t_\sigma + 1$.

4. **Item 5 of Lemma 14**
   Let $\sigma = v_0v_{i+1}\ldots v_{i+2r+2}$ be an occurrence of the pattern $02^-(02^-)^{r}0$, for some $i$, $1 \leq i \leq k - 2r - 3$. In that case, we have $t_\sigma = r + 2$.
   If $\sigma$ is an occurrence of the pattern $02(02)^{r}0$, the value of the vertices of $\sigma$ are not modified in steps 2 to 4. Therefore, we have $f_4^*(\sigma) = f_4^*(\sigma) = 2r + 1 + r + 2 = 3r + 4 = 3t_\sigma - 2$.
   Suppose now that $\sigma$ contains at least one stem having only one pendant neighbour. In step 3, the value of $f_4^*(\sigma)$ is set to 3 (and the value of $f_4^*(\sigma)$ is set to 0 if $\lambda_{i+2j+1} = 2$), and the value of every trunk is set to 0. We thus get $f_4^*(\sigma) = f_4^*(\sigma) = 2r + 1 = 3r + 3 = 3t_\sigma - 3$.

5. **Item 6 of Lemma 14**
   Let $v_0\ldots v_{2r+1}$ be an occurrence of the pattern $2^{-}(02^-)^{r}0$ (the case $02^{-}(02^-)^{r}$ is similar, by symmetry). In that case, we have $t_\sigma = r + 1$.
   In step 3, the value of $f_4^*(\sigma)$ is set to 3 (and the value of $f_4^*(\sigma)$ is set to 0 if $\lambda_{2j+1} = 2$), and the value of every trunk is set to 0. We thus get $f_4^*(\sigma) = f_4^*(\sigma) = 3(r + 1) = 3r + 3 = 3t_\sigma$. 

20
By Lemma 14, we know that there exists an optimal non-canonical independent broadcast \( \tilde{f} \) with \( \text{cost}(\tilde{f}) = \text{cost}(f) \) which satisfies all items of Lemma 14. We have proved that the non-canonical independent broadcast \( f_4 \) constructed in the proof of Lemma 10 also satisfies all items of Lemma 14. Thanks to Lemma 15, we thus have
\[
\text{cost}(f) = \text{cost}(\tilde{f}) \leq \text{cost}(f_4) = \beta^*(CT),
\]
which completes the proof. \( \square \)

We are now able to state our main result, which determines the broadcast independent number of any caterpillar with no pair of adjacent trunks.

**Theorem 17** Let \( CT = CT(\lambda_0, \ldots, \lambda_k) \) be a caterpillar of length \( k \geq 1 \), with no pair of adjacent trunks. The broadcast independence number of \( CT \) is then given by:
\[
\beta_b(CT) = \max \{ 2(\text{diam}(CT) - 1), \beta^*(CT) \}.
\]

**Proof.** We know by Observation 1 that \( \beta_b(CT) \geq 2(\text{diam}(CT) - 1) \) and we already observed that the canonical independent broadcast \( f_c \) on \( CT \) satisfies \( \text{cost}(f_c) = 2(\text{diam}(CT) - 1) \). According to Lemma 10 it is thus enough to prove that for any optimal non-canonical independent broadcast \( f \) on \( CT \) with \( \text{cost}(f) > 2(\text{diam}(CT) - 1) \), \( \text{cost}(f) \leq \beta^*(CT) \), which directly follows from Lemma 16. \( \square \)

In several cases, the value of \( \beta^*(CT) \) has a simple expression. Consider for instance a caterpillar \( CT \), of length \( k \geq 1 \), having no trunk. We then have \( \beta^*(CT) = \lambda(CT) + n_1(CT) \), where \( n_1 \) stands for the number of spine vertices having exactly one pendent vertex. Since \( \lambda(CT) \geq n_1(CT) + 2(k + 1 - n_1(CT)) = 2k + 2 - n_1(CT) \) (spine vertices have either one or at least two pendent neighbours), we get \( \beta^*(CT) \geq 2k + 2 \), with equality if and only if \( CT \) contains no stem with at least three pendent neighbours. Since \( 2(\text{diam}(CT) - 1) = 2k + 2 \), we get the following corollary of Theorem 17.

**Corollary 18** Let \( CT \) be a caterpillar of length \( k \geq 1 \) having no trunk. We then have \( \beta_b(CT) = 2k + 2 = 2(\text{diam}(CT) - 1) \) if \( CT \) has no stem with at least three pendent neighbours, and \( \beta_b(CT) = \lambda(CT) + n_1(CT) \) otherwise.

Moreover, thanks to Observation 4, we can also give the broadcast independent number of caterpillars having adjacent trunks but no stem with at least three pendent neighbours.

**Corollary 19** Let \( CT \) be a caterpillar of length \( k \geq 1 \). If \( CT \) has no stem with at least three pendent neighbours, then \( \beta_b(CT) = 2k + 2 = 2(\text{diam}(CT) - 1) \).

Finally, note that if every stem in a caterpillar \( CT \) of length \( k \geq 1 \) with no pair of adjacent trunks has at least three pendent neighbours, then no pattern involved in the definition of \( \beta^*(CT) \) can appear in \( CT \). In that case, since \( \tau(CT) \leq \left\lceil \frac{k}{2} \right\rceil \) and \( \lambda(CT) \geq 3 \left( \left\lceil \frac{k}{2} \right\rceil + 1 \right) \), we get
\[
\beta^*(CT) = \lambda(CT) + \tau(CT) > 2k + 2 = 2(\text{diam}(CT) - 1).
\]
Therefore, we have:

**Corollary 20** Let \( CT \) be a caterpillar of length \( k \geq 1 \), with no pair of adjacent trunks. If all stems in \( CT \) have at least three pendent neighbours, then \( \beta_b(CT) = \lambda(CT) + \tau(CT) \).
4. Concluding remarks

In this paper, we studied independent broadcasts of caterpillars and gave an explicit formula for the broadcast independence number of caterpillars having no pair of adjacent trunks. This result concerns a quite restricted subclass of the class of trees, but the broadcast independence number is certainly a difficult parameter to determine for trees, and probably even for caterpillars. It should be noticed here that the computational complexity of the decision problem associated with the broadcast independence number is not known yet, even for trees, although this question was already posed in [8] and [11]. (The only complexity result about a broadcast parameter, among those introduced in [8], is due to Heggernes and Lokshtanov [12], who proved that computing the broadcast domination number $\gamma_b(G)$ of any graph $G$ can be done in polynomial time.)

Finally, we consider that the following questions are of particular interest.

1. Can we determine the broadcast independence number of caterpillars? (We should notice here that for caterpillars with adjacent trunks, Lemmas 6 and 7 still hold, while Lemma 12 does not. This explains why we think that this might be a not so easy question.)

2. Can we determine the broadcast independence number of other subclasses of the class of trees? In particular, what about $k$-ary trees?

3. Can we characterize the set of caterpillars $CT$ for which $\beta_b(CT) = 2(\text{diam}(CT) - 1)$? (Partial answers are given by Corollaries 18 and 19)

4. More generally, can we characterize the set of trees $T$ for which $\beta_b(T) = k(\text{diam}(T) - 1)$, where $k$ is the maximum size of a set of pairwise antipodal vertices in $T$?
