I. INTRODUCTION

Recently, developments in wireless communication technology have seen a diversification of the communication services provided to single mobile terminals. Accordingly, dual- and multi-band microwave components are preferred for such communication systems [1], and many dual-band dual-mode filters have been studied [2–5]. To realize dual-band dual-mode characteristics, a new method of cascading two resonators has been presented [2], as well as, elsewhere, a substrate-integrated waveguide structure [3], a stepped-impedance stub resonator [4], and a stepped-impedance resonator and embedded coupled-line [5]. However, none of these structures can adjust the two resonant frequencies independently.

To address this, a dual-band dual-mode bandpass filter (BPF) based on a multi-layer structure has previously been designed [6, 7]. Dual-band operation can thereby be obtained by separately implementing a resonator on each of the two substrates; this structure is advantageous in that each operating band can be controlled independently. However, the multi-layer structure faces other challenges in terms of adjusting the alignment between the resonators on the different layers.

A dual-band dual-mode BPF implemented on a single layer is preferred because it is simpler in structure and easy to fabricate. Generally, to obtain a dual-band characteristic on a single-layer, an electrical path for each operating band must be implemented separately [8–10].

In this study, a novel dual-band dual-mode BPF based on a single microstrip ring resonator was designed. Unlike conventional dual-mode filters that use ring resonators, this filter can easily obtain a dual-band characteristic by using a non-uniform linewidth ring without an additional perturbation structure. In the proposed filter, the dual-band characteristic is obtained by simultaneously applying an inductor and a capacitor to the gap, and by combining various inductor and capacitor values, the frequency ratio of the filter can be adjusted from 1.31 to 1.83.
II. GEOMETRY

Fig. 1 shows the proposed dual-band dual-mode BPF using a single ring resonator with a non-uniform linewidth. The proposed filter structure is implemented using a substrate with a dielectric constant of 10.2 and a thickness of 50 mil, and size 1005 Murata chip inductors and capacitors are used.

If the linewidth of the ring resonator is constant, the structure operates as a single-mode filter. Typically, to obtain a dual-mode characteristic using this structure, a cut or stub is applied to change the line impedance at 45° and 135° with respect to the input and output stages. In the proposed structure, the linewidth of the ring resonator is unevenly formed, and the line impedances at 45° and 135° are automatically changed with respect to the input and output stages, thereby realizing the dual-mode characteristic.

The feed is implemented by a circular arc, and the linewidth of the feed is set to \( w \). The gap between the feed line and the resonator is set to \( g \), and the angle is set to \( \alpha \). In this study, the parameters of the feed structure are optimized using an HFSS simulator.

Fig. 2 compares the frequency response of the proposed filter

![Fig. 1. The proposed dual-band dual-mode filter.](image)

![Fig. 2 Simulated frequency responses with different dual-mode filters.](image)

in structures where only the inductor (“Inductor only”) or the capacitor (“Capacitor only”) is applied.

As shown, the resonant frequency of the filter is formed at 1.55 GHz in the case of the inductor-only filter. As the capacitor is added, the resonant frequency of the filter is lowered to the 1.3 GHz band which is the first resonant frequency of the proposed filter. The first resonant frequency can therefore be adjusted by changing the capacitor or inductor value. Meanwhile, the frequency response near 1.95 GHz, the second resonant frequency, is similar to that of the capacitor-only structure. This demonstrates that the second resonant frequency of the proposed structure is determined by the capacitor value.

III. PARAMETER STUDY

Fig. 3 shows the simulated frequency response with different inductors \( L \). At this time, \( C \) is fixed at 2.8 pF. The other parameters are as follows: \( R_1 = 12 \text{ mm}, R_2 = 8 \text{ mm}, s = 2 \text{ mm}, d_1 = 3 \text{ mm}, d_2 = 1 \text{ mm}, g = w = 0.2 \text{ mm}, \) and \( \alpha = 60° \). Although not shown, resonance does not appear in the low frequency band when inductors are absent, only appearing at 1.95 GHz. When the inductor value is 0.3 nH, a weak resonance is formed at 1.37 GHz. As the inductor value becomes larger, resonant frequency in the low frequency band decreases, and the two resonance modes are gradually split. At the same time, there is almost no change in the high frequency band. To obtain a proper dual-mode characteristic in the low-frequency band, \( L \) is therefore selected at 0.5 nH.

Fig. 4 shows the simulated frequency response with different capacitors \( C \). At this time, the 0.5 nH inductor \( L \) is applied, and the other parameters are the same as above. As the capacitor value increases, the frequency response of both bands tends to decrease simultaneously. As \( C \) increases, the two resonances split in the low frequency band but combine in the high frequency band.

![Fig. 3. Simulated frequency responses with different inductors \( L \).](image)
Fig. 5 shows the frequency response of the proposed filter as the distance $s$ changes. As $s$ increases, the low frequency band decreases downward, but the high frequency band barely changes. Further, as $s$ increases, the two resonances tend to combine in the two bands. The process of designing the proposed dual-band dual-mode BPF can therefore be presented as follows:

1. Set $R_1$, $R_2$, and $s$;
2. Set $C$ to exhibit high frequency dual-mode characteristic;
3. Add $L$ to the gap to implement dual-mode characteristic in the low frequency band. The capacitor value $C$ in the previous step will require slight tuning;
4. Optimum results can be obtained by tuning the feed.

According to this design strategy, various $L$ and $C$ combinations are applied to the original structure (Fig. 1), and the results are presented in Fig. 6.

The parameter $s$ is adjusted to obtain the appropriate filter characteristic. As $L$ and $s$ increase, the resonant frequency in the low and high bands decrease and increase, respectively. Meanwhile, as $C$ increases, the resonant frequency in the low and high bands increases and decreases, respectively. As a consequence, the frequency ratio between the two operating bands changes.

IV. SIMULATED AND MEASURED RESULTS

Fig. 7 shows the simulated and measured frequency responses of a fabricated filter. The parameters here are $R_1 = 12$ mm, $R_2 = 8$ mm, $s = 2$ mm, $d_1 = 3$ mm, $d_2 = 1$ mm, $g = \omega = 0.2$ mm, $\alpha = 60^\circ$, $L = 0.5$ nH, and $C = 2.8$ pF.

The measured passbands are centered at 1.31 GHz and 1.97 GHz with a 3-dB fractional bandwidth of 1.1% and 3.4%, respectively. The simulated minimum insertion losses of each band are $-1.71$ dB and $-2.1$ dB while the measured minimum insertion losses are $-1.86$ dB and $-2.32$ dB. Three transmission zeros with frequency locations of 1.23 GHz, 1.53 GHz, and 2.01 GHz can be clearly observed, providing sharp band-to-band rejection.

The slight discrepancy in these results is attributed to fabrication tolerance as well as the SMA connectors which were not
Fig. 8. The fabricated dual-band dual-mode filter.

considered in the simulation. The existence of insertion loss is mainly due to conductor and dielectric circuit losses and could be improved by more careful fabrication and better measurement technology. Fig. 8 presents the fabricated dual-band dual-mode filter.

V. CONCLUSION

We have proposed a novel dual-band dual-mode BPF using a ring resonator with non-uniform linewidth. The operating principles of the proposed filter are presented above, and the non-uniform linewidth of the ring is created by off-setting the patch and hole centers. The proposed filter is characteristically dual-mode; inductors and capacitors are applied to the gap, causing the filter to operate in two different bands. In addition, the frequency ratio of the proposed filter can be adjusted from 1.31 to 1.83 through various combinations of inductor and capacitor values.
