Improved Lindstedt-Poincaré method for the solution of nonlinear problems

Paolo Amore and Alfredo Aranda

Facultad de Ciencias, Universidad de Colima, Colima, Mexico

Abstract

We apply the Linear Delta Expansion (LDE) to the Lindstedt-Poincaré (“distorted time”) method to find improved approximate solutions to nonlinear problems. We find that our method works very well for a wide range of parameters in the case of the anharmonic oscillator (Duffing equation) and of the non-linear pendulum. The approximate solutions found with this method are better behaved and converge more rapidly to the exact ones than in the simple Lindstedt-Poincaré method.
I. INTRODUCTION

The study of nonlinear problems is of crucial importance in all areas of Physics. Some of the most interesting features of physical systems are hidden in their nonlinear behavior, and can only be studied with appropriate methods designed to tackle nonlinear problems. In general, given the nature of nonlinear phenomena, the approximation methods can only be applied within certain ranges of the physical parameters and or to only certain classes of problems. It is a challenge to devise nonlinear frameworks that contain both operational ease and flexibility in their application. In this paper we present a method for the solution of nonlinear problems that attempts to accomplish these features.

There are several methods which have been used to find approximate solutions to nonlinear problems. Here we just review a few. Lindstedt developed a method long time ago [1] in which one considers solutions to problems involving conservative oscillatory systems with an unknown period. The main observation is that by introducing a rescaled time, one can avoid the appearance of terms indefinitely growing with time ("secular terms"), that are common in ordinary perturbation theory. The method is now know as the Lindstedt-Poincaré (LP) method or as the Distorted Time method.

Another known technique is the perturbative $\delta$ expansion (see for example [2]). In this case the idea is to modify the exponent of the nonlinear term by introducing a parameter $\delta$ as new exponent. $\delta$ interpolates between the linear ($\delta = 0$) and the nonlinear ($\delta = 1$) problems. If one is able to solve the linear problem then the original nonlinear problem becomes, after a power expansion in $\delta$, an infinite sequence of linear problems which are (formally) solvable.

Yet another framework is the Multiple-Scale Perturbation Theory (MSPT) [3]. In this case, one tackles problems in which a dynamical system has physical behaviors at various length or time scales. This is usually problematic for ordinary perturbation theory due to the appearance (again) of secular terms. The central idea is to introduce more than one time and to treat them as independent variables. By performing the usual perturbative expansion, one then imposes conditions on the solutions (which depend on the different "times") in order to get rid of secular terms and a linear differential equation is left to solve.

Finally, the Linear Delta Expansion (LDE) [4]. This is a method in which an arbitrary (or several) parameter $\lambda$ is introduced into the problem and calculations are carried out
with conventional perturbation theory in an expansion parameter $\delta = 1$. At each order in $\delta$, the convergence of the approximation can be improved by applying the principal of minimal sensitivity which consists on a minimization of an observable with respect to the parameter $\lambda$.

All of these methods have been applied to a variety of problems. In [2], Bender et al. showed how one can obtain approximate solutions using the perturbative $\delta$ expansion and the MSPT to the Duffing equation (the classical anharmonic oscillator). Its success then has motivated their extension of the method into quantum systems [3]. The LDE method has extensively been applied in many different settings with varying degrees of success. For example, in [5] it has been used to analyze disordered systems. Pinto and collaborators have applied it to the Bose-Einstein condensation problem [6], the $O(N)(\phi^2)^d$ model [7], to the Walecka model [8] and to the $\phi^4$ theory at high temperature [9]. Detailed references can be found in these works.

We can see that it is possible to tackle a large number of nonlinear problems with these well known techniques. However, there is still room for substantial improvement over them. As mentioned before, it is desirable to have a method that works over a large range of parameters, which is not always the case in the aforementioned methods, and we would like the new method to give a smaller error in the approximations than its competitors. It is also desirable to devise a framework with operational flexibility and so easy to adapt to many different problems.

We show that the method presented in this paper accomplishes these features in the case of the Duffing equation and of the nonlinear pendulum. The method is based on the application of the LDE to the LP method [10]. We find solutions that are better behaved and that converge much faster than in the other methods described.

In Section II a brief review of the LP method is presented followed by a review of the LDE method in Section III. We then show the application of both methods to two problems, the Anharmonic Oscillator in Section IV and the nonlinear pendulum in Section V. We present our conclusions and current work in Section VI. Appendix A contains some of the formulae employed in the computations.
II. THE LINDSTEDT-POINCARÉ METHOD

In this section we introduce the Lindstedt-Poincaré distorted time (LP) method \[1\]. We consider a nonlinear ODE of the form

\[ \ddot{x}(t) + \omega^2 x(t) = \varepsilon f(x(t)), \]  

which describes a conservative system, oscillating with an unknown period \( T \). The nonlinear term \( \varepsilon f(x(t)) \) is treated as a perturbation. Unfortunately, when the ordinary perturbation is applied to eq. (1), by writing the solution as a series in \( \varepsilon \), the appearance of secular terms spoils the expansion and any predictive power is lost for sufficiently large time scales.

In order to avoid the appearance of secular terms, we switch to a scaled time \( \tau = \frac{2\pi t}{T} \equiv \Omega t \), where \( T \) is the (unknown) period of the oscillations. The ODE now reads:

\[ \Omega^2 \frac{d^2 x}{d\tau^2}(\tau) + \omega^2 x(\tau) = \varepsilon f(x(\tau)). \]  

We notice that the dependence upon \( \varepsilon \) in this equation enters both in the solution \( x(\tau) \) and in the frequency \( \Omega \). By assuming \( \varepsilon \) to be a small parameter we write

\[ \Omega^2 = \sum_{n=0}^{\infty} \varepsilon^n \alpha_n ; \quad x(\tau) = \sum_{n=0}^{\infty} \varepsilon^n x_n(\tau) \]

and expand the r.h.s of eq. (2) as

\[
\begin{align*}
 f(x) &= f \left( \sum_{n=0}^{\infty} \varepsilon^n x_n(\tau) \right) \\
 &\approx f(x_0) + \varepsilon x_1 f'(x_0) + \varepsilon^2 \left[ x_2 f'(x_0) + \frac{x_2^2}{2} f''(x_0) \right] \\
 &\quad + \varepsilon^3 \left[ x_3 f'(x_0) + x_2 x_1 f''(x_0) + \frac{x_3^3}{6} f'''(x_0) \right] + O(\varepsilon^4).
\end{align*}
\]

By using these expansions inside eq. (2) we obtain a system of linear inhomogeneous differential equations, each corresponding to a different order in \( \varepsilon \). Let us consider the first few terms. To order \( \varepsilon^0 \) we obtain the equation

\[ \alpha_0 \frac{d^2 x_0}{d\tau^2} + \omega^2 x_0(\tau) = 0, \]

(3)

describing a harmonic oscillator of frequency \( \Omega = \sqrt{\alpha_0} = \omega \). To order \( \varepsilon \) we obtain the equation

\[ \alpha_0 \frac{d^2 x_1}{d\tau^2} + \omega^2 x_1(\tau) = s_1(\tau), \]

(4)
where the r.h.s. is given by
\[ s_1(\tau) \equiv -\alpha_1 \frac{d^2 x_0}{d \tau^2} + f(x_0). \]  

We stress the oscillatory behavior of the driving term \( s_1(\tau) \), because of its dependence upon the order-0 solution, \( x_0(\tau) \). As a result \( s_1(\tau) \) will contain the fundamental frequency, corresponding to a period of \( 2\pi \) in the scaled time, and multiples of this frequency, appearing through the term \( f(x_0(\tau)) \). The presence of a driving term with the fundamental frequency leads to a resonant behavior of \( x_1(\tau) \) and to the unfortunate occurrence of secular terms, which spoils our expansion. However, we can deal with this problem by fixing the coefficient \( \alpha_1 \) to cancel the resonant term in the r.h.s. of eq. (4). The iteration of this procedure to a given order \( n \) allows to determine the coefficients \( \alpha_0, \ldots, \alpha_n \) and therefore the frequency \( \Omega = \sqrt{\alpha_0 + \epsilon \alpha_1 + \ldots + \epsilon^n \alpha_n} \).

III. LINEAR DELTA EXPANSION

The linear delta expansion (LDE) is a powerful technique which has been originally introduced to deal with problems of strong coupling Quantum Field Theory, for which the naive perturbative approach is not useful. Since then this method has been applied to a wide class of problems \([5, 6, 7, 8, 9]\). In its original formulation a lagrangian density \( \mathcal{L} \), which is not exactly solvable, is interpolated with a solvable lagrangian \( \mathcal{L}_0(\lambda) \), depending upon one (or more) parameters \( \lambda \):

\[ \mathcal{L}_\delta = \mathcal{L}_0(\lambda) + \delta (\mathcal{L} - \mathcal{L}_0(\lambda)). \]  

For \( \delta = 0 \) one obtains \( \mathcal{L}_0(\lambda) \), whereas for \( \delta = 1 \) one recovers the full lagrangian \( \mathcal{L}_\delta \). The term \( \delta (\mathcal{L} - \mathcal{L}_0) \) is treated as a perturbation and \( \delta \) is used to keep track of the perturbative order. Eventually \( \delta \) is set to be 1.

We notice that the interpolation of the full lagrangian with the solvable one, \( \mathcal{L}_0(\lambda) \), brings an artificial dependence upon the arbitrary parameter \( \lambda \). Such dependence, which would vanish if all perturbative orders were calculated, can be soften to a finite perturbative order, by requiring some physical observable \( \mathcal{O} \) to be locally insensitive to \( \lambda \), i.e:

\[ \frac{\partial \mathcal{O}(\lambda)}{\partial \lambda} = 0. \]

This condition is known as Principle of Minimal Sensitivity (PMS) and is normally seen to improve the convergence to the exact solution.
IV. ANHARMONIC OSCILLATOR

In this Section we apply the LDE to the LP method in order to find approximate solutions to the Duffing equation, a problem which has already been considered in [10]; here we present the calculation in more detail.

Consider the equation for the anharmonic oscillator

\[ \frac{d^2 x}{dt^2}(t) + \omega^2 \ x(t) = -\mu \ x^3(t) \ . \]  

(7)

This equation describes a conservative system, where the total energy is given by

\[ E = \frac{\dot{x}^2}{2} + \left[ \frac{\omega^2 \ x^2}{2} + \mu \ x^4 \right] . \]

(8)

The period of the oscillation can be calculated in terms of an elliptic integral

\[ T_{\text{exact}} = 2 \int_{-A}^{A} dx \frac{1}{\sqrt{2(E - V(x))}} , \]

(9)

where \( A \) is the amplitude of the oscillations.

Following the procedure explained in the Section II and III we write Eq. (7) as

\[ \Omega^2 \frac{d^2 x}{d\tau^2}(\tau) + \left( \omega^2 + \lambda^2 \right) \ x(\tau) = \delta \left[ -\mu \ x^3(\tau) + \lambda^2 \ x(\tau) \right] , \]

(10)

where an arbitrary parameter \( \lambda \) with dimension of frequency has been introduced. Clearly for \( \delta = 1 \), Eq. (10) reduces to Eq. (7). We repeat the procedures previously explained and find a hierarchy of linear inhomogeneous differential equations to be solved sequentially.

1. Zeroth Order

To zeroth order we obtain the equation

\[ \alpha_0 \frac{d^2 x_0}{d\tau^2} + \left( \omega^2 + \lambda^2 \right) \ x_0(\tau) = 0 , \]

(11)

with solution

\[ x_0(\tau) = A \ \cos \ \tau . \]

(12)

The zeroth order frequency is then given by

\[ \alpha_0 = \omega^2 + \lambda^2 . \]  

(13)
2. First Order

To first order we find the equation

\[ \alpha_0 \frac{d^2 x_1}{d\tau^2} + (\omega^2 + \lambda^2) x_1(\tau) = S_1(\tau), \]  

where

\[ S_1(\tau) = A \cos \tau \left[ \alpha_1 + \lambda^2 - \frac{3A^2 \mu}{4} \right] - \frac{A^3 \mu}{4} \cos 3\tau. \]  

Now \( \alpha_1 \) is fixed by eliminating the term proportional to \( \cos \tau \):

\[ \alpha_1 = \frac{3A^2 \mu}{4} - \lambda^2. \]  

We obtain the solution

\[ x_1(\tau) = -\frac{A^3 \mu}{32(\omega^2 + \lambda^2)} \cos \tau + \frac{A^3 \mu}{32(\omega^2 + \lambda^2)} \cos 3\tau, \]

and the frequency

\[ \Omega^2 = \alpha_0 + \alpha_1 = \omega^2 + \frac{3A^2 \mu}{4}, \]

which is observed to be independent of \( \lambda \).

3. Second Order

The second order equation is given by

\[ \alpha_0 \frac{d^2 x_2}{d\tau^2} + (\omega^2 + \lambda^2) x_2(\tau) = S_2(\tau), \]

where now

\[ S_2(\tau) = \frac{A (3A^4 \mu^2 + 128 \alpha_2 (\omega^2 + \lambda^2))}{128 (\omega^2 + \lambda^2)} \cos \tau \]

\[ + \frac{A^3 \mu (3A^2 \mu - 4 \lambda^2)}{16 (\omega^2 + \lambda^2)} \cos 3\tau \]

\[ - \frac{3A^5 \mu^2}{128 (\omega^2 + \lambda^2)} \cos 5\tau. \]  

As before \( \alpha_2 \) is fixed by eliminating the term proportional to \( \cos \tau \):

\[ \alpha_2 = -\frac{3A^4 \mu^2}{128 (\omega^2 + \lambda^2)}. \]
We obtain the solution

\[ x_2(\tau) = \frac{A^3 \mu (23A^2 \mu - 32\lambda^2)}{1024(\omega^2 + \lambda^2)^2} \cos \tau + \frac{A^3 \mu (-3A^2 \mu + 4\lambda^2)}{128(\omega^2 + \lambda^2)^2} \cos 3\tau + \frac{A^5 \mu^2}{1024(\omega^2 + \lambda^2)^2} \cos 5\tau \]  

(21)

and the frequency

\[ \Omega^2 = \alpha_0 + \alpha_1 + \alpha_2 = \omega^2 + \frac{3A^2 \mu}{4} - \frac{3A^4 \mu^2}{128 (\omega^2 + \lambda^2)}. \]  

(22)

Note that at this order the frequency now depends on the arbitrary parameter \( \lambda \). However, due to the explicit dependence, by applying the PMS, we would obtain the same solution as in the simple LP method (\( \lambda = 0 \)). In order to get a different solution, we must go to the next order in the expansion.

4. Third Order

Following the same procedure, we obtain the following expression for the third order:

\[ \alpha_0 \frac{d^2 x_3}{d\tau^2} + (\omega^2 + \lambda^2) x_3(\tau) = S_3(\tau), \]  

(23)

where

\[ s_3(\tau) = \left[ A \alpha_3 - \frac{3 A^5 \mu^2 (3 A^2 \mu - 4 \lambda^2)}{512 (\omega^2 + \lambda^2)^2} \right] \cos \tau - \frac{(A^3 \mu (297 A^4 \mu^2 - 768 A^2 \mu \lambda^2 + 512 \lambda^4))}{2048 (\omega^2 + \lambda^2)^2} \cos 3\tau + \frac{3 A^5 \mu^2 (3 A^2 \mu - 4 \lambda^2)}{256 (\lambda^2 + \omega^2)^2} \cos 5\tau - \frac{3 A^7 \mu^3}{2048 (\lambda^2 + \omega^2)^2} \cos 7\tau. \]  

(24)

By eliminating the term proportional to \( \cos \tau \) we determine \( \alpha_3 \) to be

\[ \alpha_3 = \frac{3 A^4 \mu^2 (3 A^2 \mu - 4 \lambda^2)}{512 (\lambda^2 + \omega^2)^2}, \]  

(25)

and the solution

\[ x_3(\tau) = -\frac{A^3 \mu}{32768} \frac{547 A^4 \mu^2 - 1472 A^2 \mu \lambda^2 + 1024 \lambda^4}{(\lambda^2 + \omega^2)^3} \cos \tau + \frac{A^3 \mu}{16384} \frac{297 A^4 \mu^2 - 768 A^2 \mu \lambda^2 + 512 \lambda^4}{(\lambda^2 + \omega^2)^3} \cos 3\tau + \frac{A^5 \mu^2}{2048} \frac{(-3 A^2 \mu + 4 \lambda^2)}{(\lambda^2 + \omega^2)^3} \cos 5\tau + \frac{A^7 \mu^3}{32768} \frac{1}{(\lambda^2 + \omega^2)^3} \cos 7\tau. \]
The frequency to order $\delta^3$ is now obtained to be

$$\Omega^2 = \alpha_0 + \alpha_1 + \alpha_2 + \alpha_3 = \omega^2 + \frac{3A^2\mu}{4} - \frac{3A^4\mu^2}{128(\omega^2 + \lambda^2)} + \frac{3A^4\mu^2(3A^2\mu - 4\lambda^2)}{512(\lambda^2 + \omega^2)^2}. \quad (26)$$

This time, the frequency depends upon the arbitrary parameter $\lambda$ in a nontrivial way and we can apply the PMS in order to fix the value of $\lambda$. We do this by imposing that $\frac{d\Omega^2}{d\lambda} = 0$, which leads to the following result:

$$\lambda^2 = \frac{3A^2\mu}{4}. \quad (27)$$

Notice that since $\lambda$ depends linearly upon $A$ the formula for $\Omega^2$ obtained in this case does not simply correspond to an expansion in $A$. As a matter of fact we find that the frequency corresponding to this value of $\lambda$ is

$$\Omega^2 = \frac{64A^4\mu^2 + 192A^2\mu\omega^2 + 128\omega^4}{96A^2\mu + 128\omega^2}. \quad (28)$$

Notice that the Duffing equation (7) is left invariant under the simultaneous rescaling of the anharmonic coupling $\mu$ and of the amplitude, i.e. $\mu \to \mu'$ and $A \to A' = A \sqrt{\mu/\mu'}$. This invariance is manifest in the equation (28), which is function of $A^2\mu$, which is invariant under this rescaling.
In Fig. 1 we compare the exact frequency, calculated with Eq. (9) with the frequency obtained with our method (LPLDE), equation (28), and with the LP method, equation (26) taking $\lambda = 0$, both to third order in perturbation theory. We take $\omega = \mu = 1$ (see the left plot of Fig. 3) and vary the amplitude of the oscillations. We observe that our method yields an excellent approximation to the exact result even for large amplitudes, where the simple LP approximation fails.

In Fig. 2 we consider the case studied in Fig. 1 but choosing $\omega = 1$ and $\mu = -1$ (see the right plot of Fig. 3). In this case the potential has a local minimum in the origin and two maxima, located at $x = \pm 1$. Periodic solutions are supported only for amplitudes $A < 1$, $A = 1$ being a point of (unstable) equilibrium, where the period diverges. Also in this case, the LPLDE method offers an excellent approximation to the exact result for a large range of amplitudes; as expected, the approximation is poorer in the region $A \approx 1$, where the point of equilibrium is approached.

In Fig. 4 we compare the period obtained with our method to the exact period of Eq. (9) and to the one obtained with the formulae of [2], which are obtained by applying the nonlinear delta expansion. Our method provides an excellent approximation to the exact period over a wide range of the parameter $\mu$, which controls the nonlinearity. The plots are obtained assuming $\omega = 1$ and the boundary conditions $x(0) = 1$ and $\dot{x}(0) = 0$. The formulae
FIG. 3: Anharmonic potential corresponding to A) $\omega = \mu = 1$ and B) $\omega = 1$ and $\mu = -1$.  

of [2] behave badly in the region $\mu < 0$, which corresponds to a potential well of finite depth centered around $x = 0$, and yield a precision comparable to the one achieved with our method for $\mu > 0$. Corresponding to the value $\mu = 0$ the oscillator is in a position of (unstable) equilibrium and the exact period diverges. Notice that for large values of $\mu$ all the methods seem to give a good approximation to the exact solution, including the LP method (to first order), which (to third order) was behaving poorly in the case previously studied. Unfortunately the equations of [2] are not suitable to be analyzed as in Fig. I and thus we cannot fully test the efficiency of this method.

In Fig. 5 we plot the relative error corresponding to the different approximations for $\mu > 0$. Our method to third order in perturbation theory yields an error typically smaller than the errors of the other methods and with a magnitude of about 0.1%.

V. THE NONLINEAR PENDULUM

We now apply the improved method to the nonlinear pendulum. The steps are exactly the same as before and we proceed to outline them. First, consider the equation for the nonlinear pendulum

$$\frac{d^2\theta}{dt^2} + \omega^2 \sin \theta = 0,$$

(29)

where $\omega^2 = g/l$ is the natural frequency of the small oscillations of the pendulum. Following the Lindstedt-Poincaré method, we introduce a scaled time $\tau = \Omega t$ and write the equation
FIG. 4: Period of the anharmonic oscillator. The curves labeled with BMPS refer to the formulas of [2].

as

\[ \Omega^2 \frac{d^2 \theta}{d\tau^2} + \omega^2 \sin \theta = 0 , \quad (30) \]

where \( \Omega = \frac{2\pi}{T} \) is the (unknown) frequency and \( T \) is the period of the oscillations. As discussed in the case of the anharmonic oscillator, we can apply the Linear Delta Expansion to the problem by modifying the above equation and writing it as:

\[ \Omega^2 \frac{d^2 \theta}{d\tau^2} + \lambda^2 \theta = \delta \left[ -\omega^2 \sin \theta + \lambda^2 \theta \right] \equiv \delta f(\theta) , \quad (31) \]

where \( \lambda \) is an arbitrary parameter, with the dimension of frequency. In what follows we use the same procedure previously outlined for the anharmonic oscillator, with a few technical differences due to the more difficult nature of the present problem.

We will expand the angle and the frequency as

\[ \theta(\tau) = \sum_{n=0}^{\infty} \delta^n \theta_n(\tau) \quad , \quad \Omega^2 = \sum_{n=0}^{\infty} \delta^n \alpha_n . \]

We will solve Eq. (31) subject to the boundary condition \( \theta(0) = A \) and \( \dot{\theta}(0) = 0 \), i.e.

\[ \theta_0(0) = A \quad , \quad \theta_{j>0}(0) = 0 \quad , \quad \dot{\theta}_j = 0 . \quad (32) \]
FIG. 5: Error corresponding to the different approaches for the case studied in Fig. The curves labeled with BMPS refer to the formulas of [2].

5. Zeroth Order

To zeroth order the equation for the pendulum reads

$$\alpha_0 \frac{d^2 \theta_0}{d\tau^2} + \lambda^2 \theta_0 = 0,$$

and we obtain the solution

$$\theta_0(\tau) = A \cos \tau,$$

describing a simple oscillatory motion with (scaled) period $2\pi$. The zeroth order frequency is therefore given by

$$\alpha_0 = \lambda^2.$$

6. First Order

To first order we obtain the differential equation:

$$\alpha_0 \frac{d^2 \theta_1}{d\tau^2} + \lambda^2 \theta_1 = S_1(\tau),$$
where we have defined the source term:

\[ S_1(\tau) \equiv -\alpha_1 \frac{d^2 \theta_0}{d\tau^2} + f(\theta_0) = A \alpha_1 \cos \tau + \left[ -\omega^2 \sin(A \cos \tau) + \lambda^2 A \cos \tau \right]. \quad (37) \]

As before, in order to avoid the occurrence of secular terms, we need to eliminate contributions proportional to \( \cos \tau \) from the source term \( S_1(\tau) \) (recall that such a term would yield a resonant behavior of the solution \( \theta_1(\tau) \)). We enforce this condition by requiring that

\[ \frac{1}{\pi} \int_0^{2\pi} d\tau \ S_1(\tau) \ e^{i\tau} = 0. \quad (38) \]

As a result of this operation, we are able to fix the coefficient \( \alpha_1 \):

\[ \alpha_1 = \frac{1}{A} \left[ -\lambda^2 A + \frac{\omega^2}{\pi} \int_0^{2\pi} d\tau \ \sin(A \cos \tau) \ e^{i\tau} \right] = \frac{1}{A} \left[ -\lambda^2 A + \omega^2 c_1 \right], \quad (39) \]

where we have used the following expansion of \( \sin(A \cos \tau) \):

\[ \sin(A \cos \tau) = \sum_{j=0}^{\infty} c_{2j+1} \cos[(2j+1)\tau], \quad (40) \]

and

\[ c_{2j+1} = \frac{1}{\pi} \int_0^{2\pi} d\tau \ e^{i(2j+1)\tau} \sin(A \cos \tau) = 2 \ (-1)^j \ J_{2j+1}(A). \quad (41) \]

Eq. (36) now reads

\[ \alpha_0 \frac{d^2 \theta_1}{d\tau^2} + \lambda^2 \theta_1 = S_1(\tau) = -\omega^2 \sum_{j=1}^{\infty} c_{2j+1} \cos[(2j+1)\tau], \quad (42) \]

where the sum starts from \( j = 1 \) because of the vanishing of the term proportional to \( \cos \tau \).

We write the solution \( \theta_1(\tau) \) as

\[ \theta_1(\tau) = \sum_{j=0}^{\infty} d_{2j+1}^{(1)} \cos[(2j+1)\tau], \quad (43) \]

where the coefficients are (for \( j > 1 \)):

\[ d_{2j+1}^{(1)} = \frac{\omega^2 c_{2j+1}}{4 \lambda^2 j (j+1)} \equiv \frac{\vec{d}_{2j+1}^{(1)}}{\lambda^2}. \quad (44) \]

In the last equation we have introduced the scale coefficients \( \vec{d}_{2j+1}^{(1)} \), which do not depend upon \( \lambda \). We notice that Eq. (42) cannot be used to determine the coefficient corresponding to \( j = 0 \); in fact, this coefficient is fixed by the boundary condition:

\[ \theta_1(0) = \sum_{j=0}^{\infty} d_{2j+1}^{(1)} = 0, \quad (45) \]

which entails

\[ d_1^{(1)} = -\sum_{j=1}^{\infty} d_{2j+1}^{(1)} = -\sum_{j=1}^{\infty} \frac{\omega^2 c_{2j+1}}{4 \lambda^2 j (j+1)} \equiv \frac{\vec{d}_1^{(1)}}{\lambda^2}. \quad (46) \]
7. Second Order

To second order we obtain the equation:

\[ \alpha_0 \frac{d^2 \theta_2}{d\tau^2} + \lambda^2 \theta_2 = S_2(\tau), \tag{47} \]

where we have introduced the source term

\[ S_2(\tau) \equiv -\alpha_1 \frac{d^2 \theta_1}{d\tau^2} - \alpha_2 \frac{d^2 \theta_0}{d\tau^2} + \theta_1(\tau) f'(\theta_0) \]
\[ = -\alpha_1 \frac{d^2 \theta_1}{d\tau^2} - \alpha_2 \frac{d^2 \theta_0}{d\tau^2} + \theta_1(\tau) \left[ -\omega^2 \cos \theta_0(\tau) + \lambda^2 \right]. \tag{48} \]

We can expand the source term in a series as

\[ S_2(\tau) = \sum_{n=1}^{\infty} s_{2n+1}^{(2)} \cos(2n+1)\tau, \tag{49} \]

where the coefficients of the expansion are given by

\[ s_{2n+1}^{(2)} = \frac{1}{\pi} \int_0^{2\pi} d\tau \, e^{i(2n+1)\tau} \, S_2(\tau) \equiv \frac{s_{2n+1}^{(2a)}}{\lambda^2} + s_{2n+1}^{(2b)}. \tag{50} \]

We have introduced the scaled coefficients \( s_{2n+1}^{(2a)} \) and \( s_{2n+1}^{(2b)} \), which are independent of \( \lambda \) and read:

\[ s_{2n+1}^{(2a)} = \frac{\omega^2}{A} \frac{c_1}{(2n+1)^2} \tilde{d}_{2n+1}^{(1)}, \]
\[ s_{2n+1}^{(2b)} = -4n \left( n+1 \right) \tilde{d}_{2n+1}^{(1)}. \]

The coefficients \( \tilde{c}_{2j} \) follow from the expansion of \( \cos[A \cos \tau] \):

\[ \cos[A \cos \tau] = \sum_{j=0}^{\infty} \tilde{c}_{2j} \cos[2j \tau] \tag{51} \]

and read, for \( j > 0 \),

\[ \tilde{c}_{2j} \equiv \frac{1}{\pi} \int_0^{2\pi} d\tau \cos[A \cos \tau] \, e^{i \, 2j \, \tau} \]
\[ = 2 \sum_{n=j}^{\infty} (-1)^n \frac{(A/2)^{2n}}{(n-j)! \, (n+j)!} = 2 \left( -1 \right)^j J_{2j}(A) \tag{52} \]

and, for \( j = 0 \),

\[ \tilde{c}_0 = \cos A - \sum_{j=1}^{\infty} \tilde{c}_{2j}. \tag{53} \]
As before we need to eliminate the coefficient $s_{1}^{(2)}$

$$s_{1}^{(2)} = \alpha_1 d_1^{(1)} + \alpha_2 A + \lambda^2 d_1^{(1)} - \frac{\omega^2}{2} \sum_{j=0}^{\infty} d_{2j+1}^{(1)} (\tilde{c}_j + \tilde{c}_{j+2}) - \frac{\omega^2}{2} d_1^{(1)} \tilde{c}_0 \quad (54)$$

and obtain the coefficient $\alpha_2$

$$\alpha_2 = \frac{1}{A} \left\{ -\left( \frac{\omega^2 c_1}{A} - \frac{\omega^2 \tilde{c}_0}{2} \right) \frac{d_1^{(1)}}{\lambda^2} + \frac{\omega^2}{2 \lambda^2} \sum_{j=0}^{\infty} d_{2j+1}^{(1)} (\tilde{c}_j + \tilde{c}_{j+2}) \right\} \equiv \frac{\sigma_2}{\lambda^2}, \quad (55)$$

where $\sigma_2 = \lambda^2 \alpha_2$ is a scaled coefficient, independent of $\lambda$.

We are therefore able to find the solution of Eq. (47)

$$\theta_2(\tau) = \sum_{j=0}^{\infty} d_{2j+1}^{(2)} \cos[(2j + 1)\tau], \quad (56)$$

with the coefficients, for $j \neq 1$

$$d_{2j+1}^{(2)} \equiv \frac{d_{2j+1}^{(2a)}}{\lambda^4} + \frac{d_{2j+1}^{(2b)}}{\lambda^2}, \quad (57)$$

expressed in terms of the $\lambda$-independent terms:

$$\frac{d_{2j+1}^{(2a)}}{d_{2j+1}^{(2b)}} = -\frac{s_{2j+1}^{(2a)}}{4 j (j + 1)},$$

$$\frac{d_{2j+1}^{(2b)}}{d_{2j+1}^{(2b)}} = -\frac{s_{2j+1}^{(2b)}}{4 j (j + 1)} = d_{2j+1}^{(1)}. \quad (58)$$

As before the $j = 0$ coefficient is not fixed by the equation and needs to be determined by enforcing the boundary condition $\theta_2(0) = 0$. We obtain:

$$d_{1}^{(2)} = -\sum_{j=1}^{\infty} d_{2j+1}^{(2)} = \sum_{j=1}^{\infty} \frac{s_{2j+1}^{(2)}}{4 \lambda^2 j (j + 1)}. \quad (59)$$

8. Third Order

To third order we obtain the equation

$$\alpha_0 \frac{d^2 \theta_3}{d\tau^2} + \lambda^2 \theta_3 = S_3(\tau), \quad (60)$$

where the source term $S_3(\tau)$ is

$$S_3(\tau) \equiv -\alpha_1 \frac{d^2 \theta_2}{d\tau^2} - \alpha_2 \frac{d^2 \theta_1}{d\tau^2} - \alpha_3 \frac{d^2 \theta_0}{d\tau^2} + \left[ \theta_2(\tau) f'(\theta_0) + \frac{\theta_1^2(\tau)}{2} f''(\theta_0) \right]. \quad (60)$$
Once again it is useful to expand the source term in a series as

\[ S_3(\tau) = \sum_{n=0}^{\infty} s_{2n+1}^{(3)} \cos(2n+1)\tau, \]  

where the coefficients of the expansion are given by

\[ s_{2n+1}^{(3)} = \frac{1}{\pi} \int_0^{2\pi} d\tau \ e^{i(2n+1)\tau} S_3(\tau) = \frac{s_{2n+1}^{(3a)}}{\lambda^4} + \frac{s_{2n+1}^{(3b)}}{\lambda^2} + s_{2n+1}^{(3c)} \]  

and \( s_{2n+1}^{(3a,b,c)} \) are independent of \( \lambda \). A lengthy calculation allows to find the expressions for these coefficients, which can be found in Appendix A. Here we only write the coefficient of the term \( \cos \tau \), corresponding to \( n = 0 \):

\[ s_1^{(3)} = \alpha_1 \ d_1^{(2)} + \alpha_2 \ d_1^{(1)} + \alpha_3 \ A - \frac{\omega^2}{2} \sum_{j=0}^{\infty} \tilde{c}_{2j} \ d_{2j+1}^{(2)} - \frac{\omega^2}{2} \sum_{l=1}^{\infty} \tilde{c}_{2l} \ d_{2l-1}^{(2)} \]

\[ + \frac{\omega^2}{8} \sum_{m=0}^{\infty} \sum_{j=m}^{\infty} c_{2(j-m-1)+1} \ d_{2m+1}^{(1)} \ d_{2j+1}^{(1)} + \frac{\omega^2}{8} \sum_{j=0}^{\infty} \sum_{m=0}^{j} c_{2(-m+j)+1} \ d_{2m+1}^{(1)} \ d_{2j+1}^{(1)} \]

\[ + \frac{\omega^2}{8} \sum_{m=j+1}^{\infty} \sum_{j=0}^{\infty} c_{2(m-j)+1} \ d_{2j+1}^{(1)} \ d_{2m+1}^{(1)} + \frac{\omega^2}{8} \sum_{m=0}^{\infty} \sum_{j=0}^{m} c_{2(m-j)+1} \ d_{2j+1}^{(1)} \ d_{2m+1}^{(1)} + \frac{\omega^2}{8} \sum_{m=0}^{\infty} \sum_{j=0}^{\infty} c_{2(m+j)+1} \ d_{2j+1}^{(3)} \ d_{2m+1}^{(1)}. \]

The coefficient \( \alpha_3 \) is fixed by requiring that \( s_1^{(3)} \) vanish:

\[ \alpha_3 = \frac{\alpha_{3a}}{\lambda^4} + \frac{\alpha_{3b}}{\lambda^2}, \]

where

\[ \alpha_{3a} = -\frac{\omega^2}{A} \left\{ \left( \frac{c_1}{A} - \frac{\tilde{c}_0}{2} \right) d_1^{(2a)} + \alpha_2 \ d_1^{(1)} - \frac{1}{2} \sum_{j=0}^{\infty} (\tilde{c}_{2j} + \tilde{c}_{2j+2}) \ d_{2j+1}^{(2a)} \right\} \]

\[ + \frac{1}{8} \sum_{m=0}^{\infty} \left[ \sum_{j=m+1}^{\infty} \left( 2 \ c_{2(j-m-1)+1} + c_{2(m+j)+1} + c_{2(m+j)+3} \right) \ d_{2j+1}^{(1)} \ d_{2m+1}^{(1)} \right] \]

\[ + \sum_{j=0}^{m} \left( 2 \ c_{2(m-j)+1} + c_{2(m+j)+1} + c_{2(m+j)+3} \right) \ d_{2j+1}^{(1)} \ d_{2m+1}^{(1)} \]  

\[ \alpha_{3b} = -\frac{\omega^2}{A} \left\{ \left( \frac{c_1}{A} - \frac{\tilde{c}_0}{2} \right) d_1^{(2b)} - \frac{1}{2} \sum_{j=0}^{\infty} (\tilde{c}_{2j} + \tilde{c}_{2j+2}) \ d_{2j+1}^{(2b)} \right\} = \frac{\pi^2}{2}. \]

To this order the squared frequency reads:

\[ \Omega^2 = \alpha_{1a} + 2 \frac{\Omega^2}{\lambda^2} + \frac{\alpha_{3a}}{\lambda^4}. \]
The “principle of minimal sensitivity” yields the solution

$$\lambda^2 = -\frac{\alpha_3 a}{\alpha_2}$$

and a corresponding value of $\Omega^2$:

$$\Omega^2 = \alpha_1 a - \frac{\alpha_2^2}{\alpha_3 a}.$$ (67)

In Fig. 6 we plot the period of the nonlinear pendulum as a function of the amplitude, as obtained in the LPLDE and LP approximations, and compare the results with the exact period. We assume $\omega = 1$ and use the formulae given above truncating the infinite series to a maximum value $j_{\text{max}} = 5$. As it can be seen from the Figure, the LPLDE approximation is in excellent agreement with the exact result, up to very large amplitudes. $A = \pm \pi$ corresponds to an unstable point of equilibrium, for which the exact period diverges.

VI. CONCLUSIONS

We have presented a method for the solution of nonlinear problems which are conservative and periodic. It is based on the application of the Linear Delta Expansion to the Lindstedt-Poincaré method. We applied it to two problems: the Duffing Equation and the nonlinear pendulum. In the case of the Duffing equation we find that the new model converges faster
and with greater accuracy than the simple LP method. Also, by comparing it with methods based on the perturbative δ expansion, we show that our solution not only converges faster and more accurately, but it also works for a much wider range of parameters, including the case in which the nonlinear coupling μ is negative. In a similar fashion, we show that the method works remarkably well for the solution of the nonlinear pendulum, for which the method is implemented without performing any Taylor expansion of the potential.

We are currently working on the extension of the present method to quantum systems and multiple scale analysis [11].

APPENDIX A: COEFFICIENTS

In this Appendix we present the computation of the coefficients of \( s_{2n+1}^{(3)} \) in Eq. (62). Let us rewrite Eq. (62) in the following form:

\[
s_{2n+1}^{(3)} \equiv I_{2n+1}^{(A)} + I_{2n+1}^{(B)} + I_{2n+1}^{(C)} + I_{2n+1}^{(D)}.
\]

(A1)

We now proceed to compute each of these terms:

- \( I_{2n+1}^{(A)} \)

\[
I_{2n+1}^{(A)} = \left( \frac{\omega^2}{A} - \lambda^2 \right) (2n + 1)^2 \left[ \frac{d_{2n+1}^{(2a)}}{\lambda^4} + \frac{d_{2n+1}^{(2b)}}{\lambda^2} \right]
\]

(A2)

\[
+ \frac{\alpha_2}{\lambda^2} (2n + 1)^2 \frac{d_{2n+1}^{(1)}}{\lambda^2} + \alpha_3 \ A \ \delta_{n0}
\]

\[
\equiv \frac{i_{a}^{(1)}}{\lambda^4} + \frac{i_{a}^{(2)}}{\lambda^2} + i_{a}^{(3)}
\]

(A3)

- \( I_{2n+1}^{(B)} \)
\[ I_{2n+1}^{(B)} = -\frac{\omega^2}{2} \sum_{l=0}^{\infty} \sum_{j=0}^{\infty} \tilde{c}_{2l} \ d_{2j+1}^{(2)} \left[ \delta_{n+l-j,0} + \delta_{n+1-l+j,0} + \delta_{l+n-j,0} + \delta_{n+l+j+1,0} \right] \]
\[ \equiv \frac{j_b^{(1)}}{\lambda^4} + \frac{j_b^{(2)}}{\lambda^2} \quad (A4) \]

The four different integrals become:

- a)
  \[ I_{2n+1}^{(B1)} = -\frac{\omega^2}{2} \sum_{j=n}^{\infty} \tilde{c}_{2(j-n)} \ d_{2j+1}^{(2)} \quad (A5) \]

- b)
  \[ I_{2n+1}^{(B2)} = -\frac{\omega^2}{2} \sum_{l=n+1}^{\infty} \tilde{c}_{2l} \ d_{2(l-n-1)+1}^{(2)} \quad (A6) \]

- c)
  \[ I_{2n+1}^{(B3)} = -\frac{\omega^2}{2} \sum_{l=0}^{n} \tilde{c}_{2l} \ d_{2(n-l)+1}^{(2)} \quad (A7) \]

- d)
  \[ I_{2n+1}^{(B4)} = 0 \quad (A8) \]

Therefore we finally have that

\[ I_{2n+1}^{(B)} = -\frac{\omega^2}{2} \left[ \sum_{j=n}^{\infty} \tilde{c}_{2(j-n)} \ d_{2j+1}^{(2)} + \sum_{l=n+1}^{\infty} \tilde{c}_{2l} \ d_{2(l-n-1)+1}^{(2)} + \sum_{l=0}^{n} \tilde{c}_{2l} \ d_{2(n-l)+1}^{(2)} \right] \quad (A9) \]

\[ I_{2n+1}^{(C)} \]

\[ I_{2n+1}^{(C)} = \frac{1}{\pi} \int_{0}^{2\pi} d\tau \ e^{i \ (2n+1)\tau} \ \lambda^2 \left( \sum_{j=0}^{\infty} d_{2j+1}^{(2)} \cos(2j+1)\tau \right) = \lambda^2 \ d_{2n+1}^{(2)} \]
\[ \equiv \frac{\xi_{(1)}^{(1)}}{\lambda^2} + \xi_{(2)}^{(C)} \quad (A10) \]
\[ I_{2n+1}^{(D)} = \frac{1}{\pi} \int_0^{2\pi} d\tau \ e^{i(2n+1)\tau} \ \frac{\omega^2}{2} \sin A \cos \tau \ \left( \sum_{j=0}^{\infty} d_{2j+1}^{(1)} \cos(2j+1)\tau \right)^2 \]

\[ = \frac{1}{\pi} \int_0^{2\pi} d\tau \ e^{i(2n+1)\tau} \ \frac{\omega^2}{2} \sum_{l=0}^{\infty} c_{2l+1} \cos(2l+1)\tau \]

\[ \times \sum_{m=0}^{\infty} d_{2m+1}^{(1)} \cos(2m+1)\tau \sum_{j=0}^{\infty} d_{2j+1}^{(1)} \cos(2j+1)\tau \quad \text{(A11)} \]

We need to calculate the following integral:

\[ \mathcal{I} = \frac{1}{\pi} \int_0^{2\pi} d\tau \ e^{i(2n+1)\tau} \cos[(2j+1)\tau] \cos[(2l+1)\tau] \cos[(2m+1)\tau]. \quad \text{(A12)} \]

Using the relation

\[ \mathcal{C} = \cos[(2j+1)\tau] \cos[(2l+1)\tau] \cos[(2m+1)\tau] \]

\[ = \frac{1}{4} \left[ \cos(2(l+m+j)+3)\tau + \cos(2(l+m-j)+1)\tau + \cos(2(l-m+j)+1)\tau + \cos(2(l-m-j)-1)\tau \right], \quad \text{(A13)} \]

one obtains

\[ \mathcal{I} = \frac{1}{\pi} \int_0^{2\pi} d\tau \ e^{i(2n+1)\tau} \mathcal{C} = \frac{1}{4} \left\{ \delta_{2(n+l+m+j)+4,0} + \delta_{2(n-l-m-j)-2,0} \right. \]

\[ + \delta_{2(n+l-m+j)+2,0} + \delta_{2(n-l+m+j),0} + \delta_{2(n+l-m+j)+2,0} + \delta_{2(n-l+m-j),0} \]

\[ + \left. \delta_{2(n+l-m-j),0} + \delta_{2(n-l+m+j)+2,0} \right\}, \quad \text{(A14)} \]

and finally

\[ I_{2n+1}^{(D)} = \frac{\omega^2}{8} \sum_{l=0}^{\infty} \sum_{m=0}^{\infty} \sum_{j=0}^{\infty} c_{2l+1} d_{2m+1}^{(1)} d_{2j+1}^{(1)} \left\{ \delta_{2(n+l+m+j)+4,0} + \delta_{2(n-l-m-j)-2,0} \right. \]

\[ + \delta_{2(n+l-m+j)+2,0} + \delta_{2(n-l-m+j),0} + \delta_{2(n+l-m+j)+2,0} + \delta_{2(n-l+m-j),0} \]

\[ + \delta_{2(n+l-m-j),0} + \delta_{2(n-l+m+j)+2,0} \right\} = \frac{i d}{\lambda^4}. \quad \text{(A15)} \]

We are then left with 8 integrals that can be evaluated in the following way (we call them \( I_D^{(i)} \)):

- \( i \)

\[ I_D^{(1)} = \frac{\omega^2}{8} \sum_{l=0}^{\infty} \sum_{m=0}^{\infty} \sum_{j=0}^{\infty} c_{2l+1} d_{2m+1}^{(1)} d_{2j+1}^{(1)} \delta_{2(n+l+m+j)+4,0} = 0 \quad \text{(A16)} \]
- ii)

\[ I_D^{(2)} = \frac{\omega^2}{8} \sum_{l=0}^{\infty} \sum_{m=0}^{\infty} \sum_{j=0}^{\infty} c_{2l+1} d_{2m+1}^{(1)} d_{2j+1}^{(1)} \delta_{2(n-l-m-j)-2,0} \]

\[ = \frac{\omega^2}{8} \sum_{m=0}^{\infty} \sum_{j=0}^{\infty} c_{2(n-m-j-1)+1} d_{2m+1}^{(1)} d_{2j+1}^{(1)} \] (A17)

- iii)

\[ I_D^{(3)} = \frac{\omega^2}{8} \sum_{l=0}^{\infty} \sum_{m=0}^{\infty} \sum_{j=0}^{\infty} c_{2l+1} d_{2m+1}^{(1)} d_{2j+1}^{(1)} \delta_{2(n+l-m-j)+2,0} \]

\[ = \frac{\omega^2}{8} \sum_{m=0}^{\infty} \sum_{j=n+m+1}^{\infty} c_{2(j-n-m-1)+1} d_{2m+1}^{(1)} d_{2j+1}^{(1)} \] (A18)

- iv)

\[ I_D^{(4)} = \frac{\omega^2}{8} \sum_{l=0}^{\infty} \sum_{m=0}^{\infty} \sum_{j=0}^{\infty} c_{2l+1} d_{2m+1}^{(1)} d_{2j+1}^{(1)} \delta_{2(n-l-m+j),0} \]

\[ = \frac{\omega^2}{8} \sum_{j=0}^{\infty} \sum_{m=0}^{\infty} c_{2(n-m+j)+1} d_{2m+1}^{(1)} d_{2j+1}^{(1)} \] (A19)

- v)

\[ I_D^{(5)} = \frac{\omega^2}{8} \sum_{l=0}^{\infty} \sum_{m=0}^{\infty} \sum_{j=0}^{\infty} c_{2l+1} d_{2m+1}^{(1)} d_{2j+1}^{(1)} \delta_{2(n+l-m+j)+2,0} \]

\[ = \frac{\omega^2}{8} \sum_{m=n+j+1}^{\infty} \sum_{j=0}^{\infty} c_{2(m-n-j-1)+1} d_{2j+1}^{(1)} d_{2m+1}^{(1)} \] (A20)

- vi)

\[ I_D^{(6)} = \frac{\omega^2}{8} \sum_{l=0}^{\infty} \sum_{m=0}^{\infty} \sum_{j=0}^{\infty} c_{2l+1} d_{2m+1}^{(1)} d_{2j+1}^{(1)} \delta_{2(n-l+m-j),0} \]

\[ = \frac{\omega^2}{8} \sum_{m=0}^{\infty} \sum_{j=0}^{\infty} c_{2(m+n-j)+1} d_{2j+1}^{(1)} d_{2m+1}^{(1)} \] (A21)
\(-vii)\)

\[
I_D^{(7)} = \frac{\omega^2}{8} \sum_{l=0}^{\infty} \sum_{m=0}^{\infty} \sum_{j=0}^{\infty} c_{2l+1} d_{2m+1}^{(1)} d_{2j+1}^{(1)} \delta_{2(n+l-m-j),0}
\]

\[
= \frac{\omega^2}{8} \sum_{m=\max(0,n-j)+1}^{\infty} \sum_{j=0}^{m+n} c_{2(m+j-n)+1} d_{2j+1}^{(1)} d_{2m+1}^{(1)}
\]

\(-viii)\)

\[
I_D^{(8)} = \frac{\omega^2}{8} \sum_{l=0}^{\infty} \sum_{m=0}^{\infty} \sum_{j=0}^{\infty} c_{2l+1} d_{2m+1}^{(1)} d_{2j+1}^{(1)} \delta_{2(n-l+m+j)+2,0}
\]

\[
= \frac{\omega^2}{8} \sum_{m=0}^{\infty} \sum_{j=0}^{m+n} c_{2(n+m+j+1)+1} d_{2j+1}^{(1)} d_{2m+1}^{(1)}
\]

The final expression is:

\[
I_{2n+1}^{(D)} = \frac{\omega^2}{8} \left\{ \sum_{m=0}^{n-j-1} \sum_{j=0}^{n-1} c_{2(n-m-j-1)+1} d_{2m+1}^{(1)} d_{2j+1}^{(1)} + \sum_{m=0}^{\infty} \sum_{j=n+m+1}^{\infty} c_{2(j-n-m-1)+1} d_{2m+1}^{(1)} d_{2j+1}^{(1)}
\]

\[
+ \sum_{j=0}^{\infty} \sum_{m=0}^{n+j} c_{2(n+m-j+1)} d_{2m+1}^{(1)} d_{2j+1}^{(1)} + \sum_{m=n+j+1}^{\infty} \sum_{j=0}^{\infty} c_{2(m-n-j-1)+1} d_{2j+1}^{(1)} d_{2m+1}^{(1)}
\]

\[
+ \sum_{m=0}^{\infty} \sum_{j=0}^{m+n} c_{2(m+n-j)+1} d_{2j+1}^{(1)} d_{2m+1}^{(1)} + \sum_{m=\max(0,n-j)+1}^{\infty} \sum_{j=0}^{\infty} c_{2(m+j-n)+1} d_{2j+1}^{(1)} d_{2m+1}^{(1)}
\]

\[
+ \sum_{m=0}^{\infty} \sum_{j=0}^{m+n} c_{2(n+m+j+1)+1} d_{2j+1}^{(1)} d_{2m+1}^{(1)} \right\}
\]
