Constraining dark matter-neutrino interactions with IceCube-170922A

Ki-Young Choi, Jongkuk Kim, and Carsten Rott

Department of Physics, BK21 Physics Research Division, Institute of Basic Science, Sungkyunkwan University, Suwon, Korea

Astrophysical neutrinos travel long distances from their sources to the Earth traversing dark matter halos of clusters of galaxies and that of our own Milky Way. The interaction of neutrinos with dark matter may affect the flux of neutrinos. The recent multi-messenger observation of a high energy neutrino, IceCube-170922A, can give a robust upper bound $\sigma/M_{\text{dm}} \lesssim 5.1 \times 10^{-23} \text{cm}^2/\text{GeV}$ on the interaction between neutrino and dark matter at a neutrino energy of 290 TeV allowing 90% suppression. Combining the constraints from CMB and LSS at different neutrino energies, we can constrain models of dark matter-neutrino interactions.

PACS numbers:

Introduction

Since neutrinos interact only weakly with matter they can propagate cosmological distances without attenuation and are considered to be ideal messenger particles to uncover the mysteries of distant astrophysical objects. The recent discovery of a very high energy neutrino, IceCube-170922A, was followed by multi-messenger observations including gamma-ray, X-ray, optical, and radio. Through these accompanying observations, the source of this 290 TeV neutrino could be identified as a flaring blazar located at a distance of 1421 Mpc.

New interactions of neutrinos with matter in the Universe may affect the propagation of neutrinos by reducing the flux or changing neutrino flavors. The non-diagonal or non-universal matter potential generated by new interactions modify the neutrino oscillation behavior and could result in deviation from the present expectations. Strong constraints can be obtained on non-standard interactions from atmospheric data, at the production, propagation and detection, and from neutrino experiments.

Neutrinos could have interactions with dark matter and observations of distant sources are ideal to probe such processes. Dark matter composes 26% of the mass-energy content of the present Universe and spreads all over the Universe, with more localization near galaxies and clusters of galaxies. Even though the simplest cosmological $\Lambda$CDM model assumes only gravitationally interacting dark matter, many models of particles physics predict non-gravitational interactions of dark matter with standard model particles as well as self interaction between dark matter.

The interaction of neutrinos with dark matter, denoted DM, has been considered in cosmology and neutrino observations. Before the last scattering of CMB, the interactions of DM beyond gravity leads to a suppression of the primordial density fluctuations, and thus erase the small scale structures and suppress the CMB spectrum at small scales.

In the present Universe, the interaction of neutrinos with DM can dissipate neutrinos and hence suppress the flux of neutrinos at Earth. This attenuation once was considered to explain the suppression of high-energy neutrino flux. This suppression also can be used to constrain the interaction of neutrinos and DM, especially for ultralight scalar dark matter.

Arguelles et al. considered the present-day interactions between high-energy cosmic neutrinos and the DM halo of the Milky Way. By taking the isotropic distribution of 53 high-energy neutrinos they could constrain DM-neutrino interactions, since the attenuation of the neutrino flux depends on the direction of the source and lead to the energy-dependent anisotropy.

Pandey et al. instead considered the significant flux suppression of high-energy astrophysical neutrinos due to the interactions with dark matter. They allowed 1% suppression by just assuming the traveling distance of neutrino as 200 Mpc and the cosmological DM density. With other collider search limits, they studied several effective operators for the interaction.

For a long-range interaction about the astrophysical size, the matter effects are integrated over the interaction size and may affect neutrino flavor oscillations. The neutrino flavor distribution at Earth can constrain the lepton-number symmetries.

In this letter, we consider the recent observation of the high energy neutrino, IceCube-170922A, to obtain a robust bound on the interaction of neutrinos with DM at high energy and combine our result with other bounds at different energies. As a specific example, we use a model of scalar DM with a fermion mediation.
$z = 0.3365 \pm 0.0010$ [26] corresponding to a distance $1421^{\pm2}_{-5} \text{Mpc}$ and was established through multi-messenger observations [1] and archival neutrino data analyses [23]. While blazars have long been suggested as sources of astrophysical neutrinos, a recent study concluded that they contribute not more than 27% [28] of the observed IceCube astrophysical neutrino flux [22, 30]. Given the observation of IceCube-170922A, we can for the first time study the propagation of a high energy neutrino with a known path and distance.

If neutrinos interact with dark matter, they can undergo dissipation during the propagation and may not arrive at Earth. The dissipation depends on the scattering cross section, $\sigma$, and the dark matter number density, $n$, along the path of the neutrino resulting in a suppression factor given by $\exp(-\int n \sigma ds)$. When the integration in the exponent $\int n \sigma ds$ is much larger than 1, the neutrino flux is exponentially suppressed and becomes unobservable at Earth.

Since the number density of dark matter may change with propagation, we can approximate the suppression factor as one from the cosmological dark matter and the other from dark matter in our Milky Way

$$\int_{\text{path}} \sigma n(x) dl = \int_{\text{los}} n(z) \sigma dz + \int_{\text{los}} \sigma n_{\text{gal}}(x) dl,$$

$$= \frac{\sigma}{M_{\text{dm}}} \left( \int_{\text{los}} \rho(z) dl + \int_{\text{los}} \rho_{\text{gal}}(x) dl \right).$$

(1)

Here $L$ is the distance from the neutrino source to the Earth and $n_0$ and $n_{\text{dm}}(x)$ are the DM number density in the large scale Universe and in the Milky Way. In the second term, we used the relation between DM energy density and DM mass, $\rho_{\text{dm}} = n_{\text{dm}} M_{\text{dm}}$, to convert the number density to energy density. We assume that the cosmological DM density, $\rho(z) = \rho_0 (1 + z)^3$ with $\rho_0 \simeq 1.3 \times 10^{-6}$ GeV/cm$^3$, which is the dark matter density along the path. The DM density in our Milky Way is position dependent and we assume the NFW profile [31] given by

$$\rho_{\text{gal}}(x) = \frac{\rho_s}{r_s \left(1 + \frac{r}{r_s}\right)^2}.$$  

(2)

TABLE I: Upper bound on the neutrino-DM scattering cross section from different experiments. In the first column, we specified the corresponding neutrino energy for that each experimental constraint is applied.

| Neutrino energy | $\sigma / M_{\text{dm}}$ (cm$^2$/GeV) | Exp. [Ref.] |
|-----------------|-------------------------------------|-------------|
| $\sim 100$ eV   | $6 \times 10^{-31}$                | CMB [13, 14]|
| $\sim 100$ eV   | $10^{-33}$                          | Lyman-\(\alpha\) [11] |
| 10 MeV          | $10^{-22}$                          | SN1987A [9] |
| 290 TeV         | $10^{-22}$                          | IceCube-170922A [1] |

where $\rho_s = 0.184$ GeV/cm$^3$, $r_s = 24.42$ kpc with $\rho_0 = 0.3$ GeV/cm$^3$, and $r$ is the distance from the Galactic center.

For the neutrino from IceCube-170922A with the distance $L = 1421$ Mpc, we find that the cosmological suppression factor is

$$\int_{\text{los}} \rho(z) dl = \int \rho(z) \frac{c dt}{dz} dz,$$

$$\simeq 7.2 \times 10^{21} \text{GeV/cm}^2,$$

(3)

where $dt/dz = -((1 + z) H(z))^{-1}$ and $H(z) = H_0 \sqrt{\Omega_\Lambda + \Omega_m(1 + z)^3}$. The last term was obtained using the present value $H_0 = 67.4 \text{ km/sec/Mpc}$, $\Omega_\Lambda = 0.685$, and $\Omega_m = 0.315$ [32].

For the suppression due to the DM interaction in the Milky Way, we need to consider the direction of the neutrino source and integrate the number density along the path of the neutrinos. We find that the suppression factor is

$$\int_{\text{los}} \rho_{\text{gal}}(x) dl \simeq 3.8 \times 10^{22} \text{GeV/cm}^2.$$  

(4)

For this calculation we use the well known direction of IceCube-170922A in the right ascension (RA) $77.42^{+0.85}_{-0.85}$ and declination (Dec) $+5.72^{+0.50}_{-0.30}$ to convert it to the Galactic coordinates used in $\rho_{\text{gal}}(x)$ of the Milky Way halo. We find that this result does not depend on the choice of DM halo profile, since the direction to the IceCube-170922A is not the center of the Milky Way from the Earth.

Incidentally both contributions from cosmological DM and Milky Way DM are very comparable, since the small cosmological DM density is compensated by the long distance. The observation of the high energy neutrino IceCube-170922A implies that the neutrino flux did not

\[ \quad \]

FIG. 1: Upper bound on the scattering cross section for different energy dependence of scattering of neutrinos with dark matter. The points of “IceCube” and “Lyman-\(\alpha\)” are the experimental upper bounds on the cross section for $M_{\text{dm}} = 1$ GeV at the corresponding neutrino energy. Here we used the power-law form $\sigma(E_\nu) = \sigma_0 \left(\frac{E_\nu}{\text{GeV}}\right)^n$, with index $n = 0, 2, 4$ for dotted, dashed, and solid lines respectively.
have significant suppression during its propagation. This enables us to place an upper bound on the interaction of neutrinos with dark matter. Considering that the suppression is not larger than 90% of the original flux, we require \( \int \sigma \, d\sigma / d\Omega \lesssim 2.3 \). Using Eq. (3) and Eq. (4), we can find the upper bound on the scattering cross section as

\[
\frac{\sigma}{M_{dm}} \lesssim 2.3 \times \left( \rho_{L} + \int_{\text{los}} \rho_{\text{gal}}(x) \, dx \right)^{-1} \\
\approx 5.1 \times 10^{-23} \text{ cm}^2 / \text{GeV} \quad \text{at} \quad E_{\nu} = 290 \text{ TeV},
\]

assuming that the scattering cross section does not change during the propagation.

**Upper bound on the neutrino-DM interaction at different energies.** The present bound on the scattering cross section between neutrinos and DM is summarized in Table I. The constraint from CMB and Lyman-\( \alpha \) comes from the small scale suppression of the density fluctuation that has been caused before the last scattering of photons, when the neutrino energy was around 100 eV. Our constraint from IceCube-170922A is applied for a neutrino energy of 290 TeV.

**Model of simple power-law.** As the scattering cross section could be energy dependent, we explore simple power-law forms of the energy dependence with \( n = 0, 2, 4 \) as

\[
\sigma(E_{\nu}) = \sigma_0 \left( \frac{E_{\nu}}{1 \text{ GeV}} \right)^n,
\]

where \( \sigma_0 \) is the cross section normalized at the neutrino energy at \( E_{\nu} = 1 \text{ GeV} \). In Fig. [1] we show the constraints on the scattering cross section for different energy dependence with \( n = 0, 2, 4 \). For each case, we find the upper bound on \( \sigma_0 \) as

\[
\begin{align*}
\sigma_0 / M_{dm} & \lesssim 10^{-33} \text{ cm}^2 / \text{GeV} \quad \text{for} \quad n = 0, \\
\sigma_0 / M_{dm} & \lesssim 6.3 \times 10^{-34} \text{ cm}^2 / \text{GeV} \quad \text{for} \quad n = 2, \\
\sigma_0 / M_{dm} & \lesssim 7.5 \times 10^{-45} \text{ cm}^2 / \text{GeV} \quad \text{for} \quad n = 4.
\end{align*}
\]

**Model of complex scalar DM mediated by a fermion.** For complex scalar DM with a fermionic mediator, the interaction Lagrangian will be

\[
\mathcal{L}_{\text{int}} = -g \chi N_{L} \nu_{L} + \text{h.c.,}
\]

where \( g \) is the coupling for the Yukawa interaction between complex dark matter \( \chi \), fermion \( N_{R} \), and left-handed neutrino \( \nu_{L} \). In this case, the mass of DM need to be smaller than that of the fermion for stable DM. The scattering cross section has non-trivial dependence on the masses and neutrino energy. The cross section scales as \( \sigma \propto E_{\nu}^{2} \) for \( E_{\nu} \lesssim M_{dm} \), \( \sigma \propto E_{\nu} \) for \( M_{dm} \lesssim E_{\nu} \lesssim m_{N}^{2} / (2M_{dm}) \), and \( \sigma \propto E_{\nu}^{-1} \) for \( E_{\nu} \gtrsim m_{N}^{2} / (2M_{dm}) \).

In Fig. [2] we show the scattering cross section versus neutrino energy for this model [13]. Here we fixed \( M_{dm} = 1 \text{ keV} \) and used \( m_{N} = 10 \text{ keV, 1 MeV, and 1 GeV} \) and show the behavior of the cross section with biggest coupling that satisfies the experimental bounds in Table I.

In Fig. [3] (Left), we show the contour plot in the \((M_{dm}, m_{N})\) plane which touches the constraint Lyman-\( \alpha \) (Red) or IceCube (Blue) for given couplings \( g = 0.1, 1, \) and \( 4\pi \). In the green region DM is heavier than the fermion and thus is not stable. For a given coupling, the upper and right region both the blue and red lines are allowed, since the strongest bound depends on the neutrino energy. In Fig. [3] (Right), the upper bound on the coupling is shown versus DM mass for given mediator mass with \( m_{N} = 1 \text{ keV, 1 MeV, and 1 GeV} \).

**Conclusion.** The multi-messenger observation of IceCube 170922A identified the source of the neutrino at energy 290 TeV, with the definite distance and direction. With this information we can calculate the precise suppression of the neutrino flux when there is interaction with dark matter in our Milky Way and in the Universe. By allowing a 90% suppression of the neutrino flux, we derived an upper bound on the neutrino dark matter scattering cross section as \( \sigma / M_{dm} \lesssim 5.1 \times 10^{-23} \text{ cm}^2 / \text{GeV} \) at the corresponding neutrino energy. Since the scattering cross section depends on the neutrino energy we need to combine the experimental constraints at different energies together to constrain specific micro-physics models.
