Abstract

Prenatal invasive diagnostic and therapeutic procedures have drastically reduced during COVID-19 pandemic. Unlike routine prenatal care, these are time bound and highly skilled procedures available at specialized centres. This adds to the limited accessibility for at-risk women. Major concerns including procedure related risk, exposure of health care personnel and vertical transmission of COVID-19. At newly developing tertiary centre, we had done 36 fetal procedures during pandemic including 25 amniocentesis, three chorion villus sampling and eight intrauterine transfusions. It is advisable to perform life-saving fetal interventions irrespective of COVID-19 status taking full precautions and proper counselling of women.

Keywords: Prenatal; invasive; COVID-19; challenges

Running Title: Challenges in fetal procedures during COVID-19 era

Introduction

COVID-19 pandemic has affected the health care globally and this is the reason for stress to both the patient and health workers. It has posed a major challenge in the practice of prenatal care. This is more so for prenatal invasive procedures for fetal diagnostic and therapeutic purpose [1]. The prenatal invasive procedures are done in high risk pregnancies where biochemical screen is positive for aneuploidy, fetal anomaly on ultrasound or previous history of anomalous baby is there. These procedures include chorion villus sampling (CVS), amniocentesis, cordocentesis and intrauterine transfusion for fetal anaemia, laser therapy for twin-twin transfusion syndrome and fetal shunt surgeries. Unlike routine prenatal care, these are time bound interventions sensitive to particular gestational age so these cannot be delayed or postponed. Moreover, these highly skilled procedures are available at specialized centres only. This adds to the limited accessibility of health-care by at-risk women during the pandemic where there are curfew restrictions, modified policies for hospital admissions and disruptions in routine antenatal programs. There are many concerns in performing fetal interventions. These include procedure related risk to fetus and mother, exposure of health care personnel and vertical transmission to the fetus if women tests positive for covid-19. These risks have to be weighed against the benefit of mother and fetus [2].

Our experience: At newly developing tertiary care centre in western India, we had done 36 fetal procedures during the lockdown period from April, 2020 till October, 2020. Out of this, 25 were amniocentesis and three CVS (indication being biochemical screen positive for trisomies, abnormal anomaly scan or previous affected child with congenital adrenal hyperplasia). There were eight intrauterine transfusions performed for Rh-immunisation with severe fetal anaemia. All women were tested for COVID-19 and they were reported negative. This was to ensure the safety of all patients, healthcare workers and also to counsel women regarding risk of vertical transmission in case she is positive for COVID-19. The procedures were done taking informed consent, proper precautions by staff and doctors (personal protective equipment-PPE). There were no complications in any of the procedures.

It is recommended to test all women for COVID-19 infection prior to the procedure. If women is tested positive, then the procedure should be ideally postponed till the clearance of infection. Non-invasive prenatal screening can be offered in these women due to high sensitivity of about 99% and it may be more useful in COVID-19 times as it provides wide window for testing. Certain procedures are dependent on period of gestation like intra-uterine transfusions for fetal anaemia and laser therapy for twin-twin transfusion syndrome. Hence, it is advisable to perform life-saving fetal interventions irrespective of COVID-19 status while taking full precautions so as to minimise the risk of viral transmission to health workers. The procedure in a COVID-19 positive patient should be
performed with minimal staff in the operation theatre and after wearing PPE. There is risk of vertical transmission of virus to fetus which should be explained to women and family, although it has not been proved in recent studies [4]. This risk can be further minimised by avoiding transplacental passage of the needle as far as possible and amniocentesis may be preferred to chorion villus sampling [5]. Thus, there is a major concern in performing fetal procedures during the pandemic, which should be done after proper counselling of the couple taking into account their background risks and feasibility at the facility.
