MULTIDIMENSIONAL STABLE DRIVEN MCKEAN-VLASOV SDES WITH DISTRIBUTIONAL INTERACTION KERNEL: A REGULARIZATION BY NOISE PERSPECTIVE

P.-E. CHAUDRU DE RAYNAL, J.-F. JABIR, AND S. MENOZZI

ABSTRACT. We are interested in establishing weak and strong well-posedness for McKean-Vlasov SDEs with additive stable noise and a convolution type non-linear drift with singular interaction kernel in the framework of Lebesgue-Besov spaces. In particular, we characterize quantitatively how the non-linearity allows to go beyond the thresholds obtained for linear SDEs with singular interaction kernels. We prove that the thresholds deriving from the scaling of the noise can be achieved and that the corresponding SDE can be understood in the classical sense. We also specifically characterize in function of the stability index of the driving noise and the parameters of the drift when the dichotomy between weak and strong uniqueness occurs.

1. Introduction and main result.

1.1. Framework. Fix a finite time horizon \( T > 0 \) and a starting time \( t \in [0, T) \). Let \( s \in (t, T] \) and consider the, possibly formal, McKean-Vlasov Stochastic Differential Equation (SDE)

\[
X^t_s = \xi + \int_t^s b(v, X^t_v, \mu) \mu^t_v(dy)dv + (W_s - W_t), \quad \xi \sim \mu \in \mathcal{P}(\mathbb{R}^d),
\]

with \( \mathcal{P}(\mathbb{R}^d) \) the set of probability measures on \( \mathbb{R}^d \), where the driving noise \( (W_s)_{s \geq t} \) is a symmetric \( \alpha \)-stable process with \( \alpha \in (1, 2) \) (including thus the pure jump and the Brownian cases) and \( (\mu^t_s)_{s \in [t, T]} \) denotes the (time) marginal laws of \( (X^t_s)_{s \in [t, T]} \). We aim at proving well-posedness (in a weak or strong sense) for the above equation for distributional interaction kernels \( b \). Namely, we want to consider a Lebesgue-Besov framework assuming that:

\[
b \in L^r((t, T], B_{p, q}^\beta(\mathbb{R}^d, \mathbb{R}^d)) =: L^r(B_{p, q}^\beta), \quad \beta \in (-1, 0], \quad p, q, r \in [1, +\infty]. \tag{A}
\]

Briefly, when \( p = q = +\infty \), and for any non integer \( \beta > 0 \), Besov spaces coincide with Hölder spaces with \( B^\beta_{\infty, \infty}(\mathbb{R}^d, \mathbb{R}^d) = C^\beta(\mathbb{R}^d, \mathbb{R}^d) \); when \( \beta \in (-1, 0) \), they correspond to a distribution space whose elements can be seen as the generalized derivatives of functions belonging to \( B^{\beta + 1}_{\infty, \infty}(\mathbb{R}^d, \mathbb{R}^d) = C^{\beta + 1}(\mathbb{R}^d, \mathbb{R}^d) \). This also somehow indicates that the Hölder modulus blows up at rate \( \beta \). More generally, the parameters \( p \) and \( q \) are related to the integrability of such a modulus. We refer to Section 2.6.4 of [57] or Section 2 for a precise definition of Besov spaces.

In the setting \( (A) \), we are interested in deriving conditions relating the stable exponent \( \alpha \), the integrability indexes \( r, p, q \), the regularity index \( \beta \) and the dimension \( d \) of the system in order to have well-posedness of the former equation in a weak or strong sense. In the following, the quantities \( \alpha, r, p, q, \beta \) and \( d \) are referred to as the parameters (of (A)).

The question of the well-posedness for irregular or singular non-degenerate McKean-Vlasov SDEs of the above, or even more general, form is nowadays the subject of a vast and still increasing literature. Historically, McKean-Vlasov SDEs were introduced for the probabilistic interpretation of non-linear parabolic PDEs arising as the mean-field limit of interacting particle systems, [16, 17]. At the time, H. P. McKean addressed the specific cases of a Boltzmann type equation and the (viscous) Burgers equation, and since then -particularly in the 80s’ and 90s’- McKean-Vlasov models have been applied to design and validate particle methods in a variety of situations in statistical physics and in fluid dynamics.
McKean-Vlasov SDEs were notably investigated for the validation of particle approximation and simulation of vortex particle methods for the two and three dimensional incompressible Navier-Stokes equations, and more recently the Keller-Segel equations. For a more detailed overview on the links between McKean-Vlasov models, numerical particle methods and their application in statistical physics, population dynamics, social science and other engineering fields, we refer the interested reader to the surveys \cite{bouchard2012mean,delarue2014stochastic} and the recent monographs \cite{dawson2013stochastic,gardiner2014stochastic}.

In the last decade, the theory of McKean-Vlasov SDEs has received a renewed and significant interest with the emergence of mean field games and applications of the mean-field theory and McKean-Vlasov SDEs in stochastic control problems - see \cite{hu2015mean} and the references therein. This new framework, coupled with new advances on variational calculus on the space of probability measures (e.g. \cite{ambrosio2006gradient,carmona2012probabilistic,ambrosio2008optimal} and \cite{hu2015mean}), puts the focus on well-posedness questions for McKean-Vlasov SDEs with coefficients having a general dependency in the measure argument, see e.g. \cite{carmona2013probabilistic}.

The present work is the first of a series of two. We will concentrate here on the regularization by noise aspects associated with McKean-Vlasov SDEs of type \eqref{eq:1.2} (i.e. for which the measure dependence arises from an interaction kernel). The connections with specific models and their extension to the $\alpha$-stable setting will be thoroughly investigated in the companion paper \cite{dawson2013stochastic}.

**A regularization by noise perspective.** For *standard* SDEs, i.e. when the dynamics write (at least formally in the case of a distributional drift):

\[
Y_t^{s,\mu} = \xi + \int_s^t b(v, Y_v^{s,\mu}) dv + (W_t - W_s), \quad \xi \sim \mathcal{P}(\mathbb{R}^d),
\]

and thus when there is no spatial convolution between the drift and the law, a huge literature investigated as well the smoothing effects of the noise. The underlying idea is that the presence of noise allows to restore uniqueness in some sense when the corresponding differential equation without noise would be ill-posed.

Such phenomena have for instance been studied since the seminal works of Zvonkin \cite{zvonkin1975estimates} - who established, in the scalar case, strong well-posedness for \eqref{eq:1.2} when the drift is only bounded and (Borel) measurable - and then of Stroock and Varadhan \cite{stroock1979multidimensional} - who extended the result from a weak perspective, in the multidimensional setting, allowing as well the noise to be multiplicative with a diffusion coefficient only measurable in time and space and continuous in time. The strong uniqueness result of Zvonkin was then extended to the multidimensional case by Veretennikov in \cite{veretennikov1982strong} and later for $L^r((t,T], L^p(\mathbb{R}^d, \mathbb{R}^d))$ drifts satisfying a Serrin integrability condition by Krylov and Röckner in \cite{krylov1994strong} (with recent investigation of the critical case in \cite{dawson2013stochastic, keller2017illposedness}). We can also refer to the monograph by Flandoli, \cite{flandoli2015noise}, for a survey of related topics or to the article \cite{flandoli2013vanishing} in which a vanishing viscosity restores a kind of uniqueness for a Peano type ODE by - roughly speaking - selecting the maximal solutions of the ODE (see also \cite{ambrosio2008optimal} below).

Let us also mention that the case when $b$ in \eqref{eq:1.2} is a distribution has been investigated with a growing interest. From the initial work of Bass and Chen \cite{bass2004hyperbolic}, for a scalar SDE and a time homogeneous drift, which was investigated through a Dirichlet form approach, there have been various works addressing the well-posedness of \eqref{eq:1.2} for time-dependent drifts through PDE analysis \cite{carmona2012probabilistic, carmona2013probabilistic} for local generators, \cite{ambrosio2006gradient, ambrosio2008optimal} for the strictly stable case or rough-path techniques \cite{dawson2013stochastic, delarue2014stochastic} for a Markovian setting or \cite{delarue2011well} for a purely pathwise approach which also allows to address fractional dynamics). At this point, one has to notice that the SDE \eqref{eq:1.2} is only *formal* for distributional drifts. The associated *weak* well-posedness is investigated through the martingale problem formulation, which possibly needs to be tailored, but in any case requires in the Markovian setting to investigate the well-posedness of the underlying associated PDE. Namely,

\[
\begin{aligned}
\partial_t u + b \cdot Du + L^\alpha u = -f & \quad \text{on } [0,T) \times \mathbb{R}^d, \\
u(T,\cdot) = 0,
\end{aligned}
\]

where $L^\alpha$ is the generator of the driving stable process $W$, $D$ a generalized gradient operator, and $f$ belongs to a rich enough class of functions in order to characterize the law of the canonical process associated with the martingale problem solution. Equation \eqref{eq:1.3} is to be solved in a *mild* sense through

\footnote{in the time-independent case the problem can still be investigated through Dirichlet forms, \cite{amir2015mild}}
a Duhamel type formulation. Namely we formally rewrite it as:

$$\forall (t, x) \in [0, T] \times \mathbb{R}^d, \quad u(t, x) = \int_0^T ds P^\alpha_s \{ [f + b \cdot D u](s, x) \},$$

(1.4)

where \((P^\alpha_t)_{t \geq 0}\) is the semigroup generated by \(L^\alpha\).

The point is that this (mild) formulation already emphasizes the difficulties and allows to understand the thresholds on the parameters arising for well-posedness in the aforementioned articles. Indeed, not only is the representation (1.3) implicit (in the sense that \(u\) appears on both sides of the equality) but for a distributional drift, it is delicate to give a meaning to the term \(P^\alpha_s [-b \cdot D u]\). This can somehow be done from the Bony paraproduct rule. Namely \(b \cdot D u\) can be well-defined, as a distribution, provided the sum of the regularities of each term is positive. Assume now and for a while that \(b\) is time independent and belongs to \(B^2_{\infty, \infty}(\mathbb{R}^d, \mathbb{R}^d), \beta \in (-1,0)\) (or that \(b = DB\) with \(B \in B^{2+1}_{\infty, \infty}(\mathbb{R}^d, \mathbb{R})\)). Suppose as well that the former product makes sense as a distribution. It can then only be expected to lie in the same space than \(b\), i.e. in \(B^2_{\infty, \infty}(\mathbb{R}^d, \mathbb{R})\). Thus, for any (smoother) class of functions to which \(f\) belongs to, the above mild representation suggests, from a heuristic parabolic bootstrap argument, that the best one can expect is that \(u \in C^{2+\alpha}(\mathbb{R}^d, \mathbb{R})\) with \(\beta + \alpha > \frac{3}{2}\). Thus \(Du\) is expected to belong to \(C^{2+\alpha-1}(\mathbb{R}^d, \mathbb{R})\) with \(\beta + \alpha - 1 > 0\). From the previous rule, for the product to be well defined, one should have:

$$\beta + (\beta + \alpha - 1) > 0 \iff \beta > \frac{1 - \alpha}{2}.$$  

(1.5)

This is precisely the threshold that appears in \([27, 2, 20]\) in the corresponding setting. Let us specify that in \([22, 40]\) the authors manage to go below this threshold adding some structure to the drift, i.e. assuming that this latter can be enhanced into a rough path structure. In that case the threshold can decrease to \((2 - 2\alpha) / 3\).

Even when having at hand the martingale solution, specifying rigorous integral dynamics - for an adequate notion of solution - for the formal SDE (1.2) is not easy when the drift is a distribution. Under the previously described conditions, it turns out that the integrated drift has to be understood as a Dirichlet process and it seems that the most accurate description of the singular dynamics, which reconstructs the drift as a Young integral with respect to a time-space convolution of the drift and the density of the driving noise, is provided in \([22]\) in the Brownian case and \([20]\) for the stable Young regime.

**Regularization by noise for McKean-Vlasov SDE.** In its simplest setting, notably for Brownian driven diffusions, the (strong) well-posedness of McKean-Vlasov SDEs is fulfilled whenever the coefficients are Lipschitz continuous in \(\mathbb{R}^d \times \mathcal{P}_\ell(\mathbb{R}^d), \ell \in [1, +\infty)\) and \(\mathcal{P}_\ell(\mathbb{R}^d)\) standing for the set of probability measures which admit a moment of order \(\ell\) and is equipped with the topology induced by the Wasserstein metric:

$$W_\ell(\mu, \nu) = \left( \inf_{X \sim \mu, Y \sim \nu} \mathbb{E}[|X - Y|^\ell] \right)^{1/\ell}.$$  

The distance \(W_\ell\) appears to be quite natural when dealing with McKean-Vlasov equations with Lipschitz properties, especially because it can be expressed in term of the corresponding \(L^\ell\) distance. Indeed, on the one hand, this relation allows to implement the Picard-Lindelöf fixed point procedure to establish well-posedness results, in a rather similar way than for classical SDEs. On the other hand, it allows to ensure the well-posedness of the associated Mean-Field particle system, viewed as a high dimensional SDE. We refer to e.g. \([47, 56, 38]\) and \([12]\), Section 5.7.4, for further details.

It nevertheless appears that, in the non-degenerate case, the usual Lipschitz property w.r.t. the Wasserstein metric can be weakened to a Lipschitz property w.r.t. the total variation distance defined, for any \(\mu, \nu \in \mathcal{P}(\mathbb{R}^d)\), as \(d_{TV}(\mu, \nu) = \sup_{A \in \mathcal{B}(\mathbb{R}^d)} |\mu(A) - \nu(A)|\). This goes back to the work of Shiga and Tanaka \([53]\) for a particular type of measure dependence and then to Jourdain \([35]\) in a rather general framework - in both works, the diffusion matrix is not allowed to be measure dependent. We used above the word “weakened” to refer to the fact that, for any probability measures \(\mu, \nu\) with full support on some compact subset \(K\) of \(\mathbb{R}^d\) one has, e.g. \(W_\ell(\mu, \nu) \leq \text{diam}(K)^{1/\ell} d_{TV}(\mu, \nu)\), and a large class of solutions of non-degenerate SDEs lives with high probability in compact subsets of the considered space. Hence, the non-degeneracy of the noise allows to consider this stronger topology. This particular smoothing effect of

\(^3\text{Observe that since } \beta \in (-1,0) \text{ this means in particular that } \alpha > 1. \text{ Singular drifts can be handled in the so-called sub-critical stable regime.}\)
the finite dimensional noise w.r.t. the infinite dimensional measure variable is highlighted in e.g. Section 2 in [19]. Using this quite tricky regularization phenomenon, the authors succeeded therein to derive a rather general well-posedness theory for Brownian driven McKean-Vlasov SDEs whose drift and diffusion coefficients may be Lipschitz w.r.t. stronger topologies than the usual Wasserstein metric. In this regard, we also refer the reader to [17] where the first author extended Zvonkin’s technique to McKean-Vlasov SDEs. To conclude this (partial) survey of the literature, let us finally point out the alternative methodology, highlighted in Mishura and Veretennikov [50], to quantify pathwise $d_{TV}$ distance through a change of probability measures. While initially designed to handle weak uniqueness results for Borel measurable kernels with linear growth in the space argument, this methodology has been extended to different situations, from non smooth drifts in both the spatial and measure arguments [39] to measure-dependent diffusion coefficients [51]. The use of change of probability measures remains nonetheless quite specific to Brownian driven equations and does not transpose to the general pure jump stable setting.

While often limited to the Brownian case, well-posedness results for non-degenerate stable (and pure jumps) driven McKean-Vlasov SDEs were addressed in [30] (see also [36] for more general jumps processes with suitable moments and [48] - and subsequent references - for the more specific case of the Boltzmann equation). In [30], the authors show that one can again consider stronger topologies for the regularity of the coefficients w.r.t. the measure variable and still preserve the well-posedness of the system. Let us mention as well that the approach adopted therein allows to reach the super-critical case ($\alpha < 1$).

We now briefly specify part of the results obtained in [19] and [30]. Therein, by stronger topologies, the authors roughly mean that the coefficients are Hölder (or even bounded measurable) in space and Lipschitz continuous w.r.t. the chosen distance on the space of probability measures. For two given probability measures, this latter is defined as the supremum of their difference integrated against normalized functions whose regularity is linked to the spatial one of the coefficients. Namely, measurable and bounded (for the drift coefficient in [19]) and Hölder continuous for the others. Again, the regularity assumed on the coefficients imposes, in turn, the class of test functions against which probability measures have to be tested when investigating the well-posedness of the system. From the fixed point perspective of those works, this homogeneity (between the metrics) seems rather natural. Indeed, the underlying linear problems precisely enjoy some stability on the indicated function space (Schauder type estimates).

**McKean-Vlasov SDE with distributional interaction kernel.** One of the main objectives in the current work is to take full advantage of the non-degeneracy of the noise and of the particular structure of the measure dependence (allowing, in some sense, to regularize the drift through the convolution with the law of the solution - provided the law itself is smooth enough) in order to obtain a well-posedness result for a rather large class of interaction kernels, possibly larger than the one considered in the classical measure-independent case described above. As it will be heuristically discussed below, it seems to us that such a class is, almost, the largest that could be considered in the current setting.

In order to emphasize some of the particularities of the model, let us again consider for a while that $\beta \in (-1, 0]$ and that the interaction kernel is time-homogeneous, i.e. $b \in B_{\infty, \infty}^\beta(\mathbb{R}^d, \mathbb{R}^d)$.

**Regularity with respect to the measure argument and associated metric.** Let us first formally define the measure indexed drift

$$B_\nu(x) := \int b(x - y) \nu(dy), \quad \nu \in \mathcal{P}(\mathbb{R}^d),$$

associated with the non-linear drift of equation (1.1).

Let us point out that this definition is formal in the sense that, since $b$ is singular, it is intuitively clear that some additional properties are needed on the probability measure $\nu$ for the quantity to be well defined. A rather natural way to define an appropriate setting is to proceed through duality. If we restrict to probability measures with density, i.e. $\nu(dy) = \nu(y)dy$, the integral $\int dy \ b(x - y) \nu(y)$ makes sense as soon as $\nu \in B_{1, 1}^{-\beta}(\mathbb{R}^d, \mathbb{R})$ from the inequality:

$$|B_\nu(x)| = |\int dy \ b(x - y)\nu(y)| \leq |b|_{B_{\infty, \infty}^\beta(\mathbb{R}^d, \mathbb{R})} |\nu|_{B_{1, 1}^{-\beta}(\mathbb{R}^d, \mathbb{R})},$$

(1.6)

see e.g. [44] for a thorough presentation of duality results between Besov spaces. Namely, the regularity of the density of the measure is needed to compensate the singularity of the kernel $b$ to define the corresponding drift $B_\nu$. As a consequence, this latter is then defined pointwise.
The previous considerations naturally induce a metric on the probability measures whose densities belong to $B_{1,1}^{-\beta}(\mathbb{R}^d, \mathbb{R})$ for which the corresponding measure indexed drift is Lipschitz (in its measure argument). Namely, for all $x \in \mathbb{R}^d$,

$$|B_{\nu}(x) - B_{\nu'}(x)| = \int dy b(x - y)(\nu - \nu')(y) \leq |b|_{B_{2,\infty}^{\alpha}(\mathbb{R}^d, \mathbb{R})} |\nu - \nu'|_{B_{1,1}^{-\beta}(\mathbb{R}^d, \mathbb{R})}. \quad (1.7)$$

In view of the previous discussion on the specific features of the regularization by noise for McKean-Vlasov SDEs, this thus suggests to look for (weak) solutions whose marginal laws live for almost every time in the space $B_{1,1}^{-\beta}(\mathbb{R}^d, \mathbb{R})$.

**Attainable thresholds (in term of irregularity of the interaction kernel).** Here, instead of considering the backward Kolmogorov PDE associated with (1.2), we rather investigate the (forward) non-linear Fokker-Planck equation. We are thus led to consider mild solutions of this latter of the form

$$\forall (s, y) \in [t, T] \times \mathbb{R}^d, \quad \rho(s, y) = \rho_{s-t} \ast \mu(y) + \int_t^s dP^\alpha_{s-v}[(\div (B_{\rho} \cdot \rho))](v, y), \quad (1.8)$$

where $\rho(s, \cdot)$ denotes the density function of $\mu_{s-t}^{1,\nu}$, $\ast$ the convolution product along the space variable, $\rho^\alpha$ stands for the density of the driving process in (1.1) and, again, $P^\alpha$ for the corresponding semi-group.

In comparison with (1.4), we do not need to define the product $b \cdot Du$ anymore, but only $B_{\rho} \cdot \rho$ and prove somehow that the divergence of this term will be mapped onto a suitable function space by the stable semi-group $P^\alpha$ - precisely, the space where $\rho$ is supposed to belong to, for almost every time.

According to the previous discussion, this space should be $B_{1,1}^{-\beta}(\mathbb{R}^d, \mathbb{R})$. Let us now present some formal calculations, proved below, to understand which thresholds are likely to be attainable. Recall that the space $B_{1,1}^{-\beta}(\mathbb{R}^d, \mathbb{R})$ can be described as the set of integrable maps having an integrable Hölder modulus. It will be established in Lemma 7 below, through integration by parts together with Young like convolution somehow provided we can prove somehow that the divergence of this term will be mapped onto a suitable function space by the stable semi-group $P^\alpha$ - precisely, the space where $\rho$ is supposed to belong to, for almost every time.

Indeed, the control in $L^\infty(\mathbb{R}^d, \mathbb{R}^d)$ norm of $\rho(s, \cdot)$ in (1.8) allows to “remove” the non-linearity and thus the quadratic dependence in $\rho$ in the right hand side of (1.8). This specific feature will yield well-posedness, for the indicated non-linear threshold, for any positive time $T > 0$. Such phenomenon is referred to as dequadrification in the following.

**Remark 1.**

(i) **On the associated metric and space in which the solution belongs to.** For whom are familiar with the smoothing effect of linear SDEs (as briefly described above), it would seem reasonable, in view of (1.8), to look for the law of the process in the space of probability measures whose regularity is precisely given according to the usual parabolic bootstrap associated with the non-degenerate noise. Namely, as the interaction kernel $b$ belongs to $B_{\infty,1}^{\beta,\alpha}(\mathbb{R}^d, \mathbb{R})$, the corresponding space for probability measures would be $B_{1,1}^{\beta+\alpha}(\mathbb{R}^d, \mathbb{R})$, similarly to the linear case. Note that, in the singular setting, the regularity associated with the parabolic bootstrap, i.e. $\beta + \alpha$, is greater.
or equal than the minimal regularity, i.e. $-\beta$, needed to define properly the drift (see (1.6)). Namely,

$$(\beta + \alpha) - (-\beta) = 2\beta + \alpha > 2 - 2\alpha + \alpha = 2 - \alpha,$$

meaning that, except in the Brownian case ($\alpha = 2$), the regularity of the weak solution should be better than the one obtained in this work. However, we were not able to prove such a result for any positive time $T > 0$, but only in small time. We feel that this restriction comes from the particular smoothing effect of the McKean-Vlasov SDEs previously described and the dequadrification approach, which allows to handle any initial measure but not to benefit from a potential smoothness of this latter to iterate the analysis (this feature will be one of the cores of [18] as briefly mentioned below).

(ii) On the thresholds. Let us point out that the threshold (1.10) actually corresponds to the one deriving from the scaling analysis in the linear case. Indeed consider the following scalar perturbed Peano dynamics: for $\epsilon > 0$,

$$dx^0_\epsilon = \text{sgn}(x^\epsilon_0)|x^\epsilon_0|^\beta \, ds + c_dW_s, \quad x^\epsilon_0 = 0.$$  

(1.11)

It is clear that for $\epsilon = 0$ the maximal solutions of (1.11) write: $x^0_\epsilon = \pm c_\epsilon s^{1/(1-\beta)}$. Heuristically, considering $\epsilon > 0$ allows to restore uniqueness as far as the noise dominates the maximal solution in short time. In terms of scales, recalling that the typical scale of $W_s$ is $s^{1/\alpha}$, this writes

$$s^{\frac{\alpha}{\beta}} > s^{\frac{1}{1-\beta}} \iff \frac{1}{\alpha} < \frac{1}{1-\beta} \iff \beta > 1 - \alpha,$$

recalling that $s$ is small for the first equivalence. Well-posedness of (1.11) under the condition (1.10) was precisely proved in a particular Brownian scalar setting by Gradinaru and Offret in [32]. We eventually emphasize that the above scaling argument can be made rigorous for a broad class of equations for which the scaling properties of the noise and the drift lead to some positive thresholds - in the sense that it allows to build counter-examples to weak uniqueness, see e.g. [13] [15] [19].

The main difficulty of course is to make the above arguments rigorous. This is what we will actually do considering the Fokker-Planck equation associated with the McKean-Vlasov SDE (1.1). We will not proceed through a fixed point procedure but prove that, starting from a mollified version of the drift coefficient, we can actually control the quantities we highlighted before, uniformly in the mollification parameter under a suitable condition relating the parameters, Assumption (C0) below, which is consistent with the previous discussion and enlarges the framework. The well-posedness of (1.1) is then drawn from a stability argument.

We conclude this introduction emphasizing that for physics related models, e.g. the Burgers equation considered from the origin of McKean-Vlasov SDEs, one should expect that the case $\beta = -1, \alpha = 2$ could be handled. This is not the case here because we wanted to focus on a generic approach working viewless of the regularity of the initial law. The critical cases (which saturate the previous inequalities for the thresholds) will be addressed through different tools, somehow more connected with usual arguments in non-linear analysis, in the companion paper [18]. The strategy therein will allow to take advantage of a smoother initial condition or some specific structural conditions on the drift (e.g. free divergence for fluid related problems) to go beyond the discussed thresholds.

**Organization of the paper.** Our main results are stated in the next section, and their proofs are developed in Section 3. Our strategy, presented in Section 1.3, consists first in establishing the existence of a solution to (1.1) in terms of a non-linear martingale problem, through a mollification of the drift coefficient and stability arguments. This approach allows to derive the weak well-posedness of a solution to (1.1) directly from the construction of its marginal laws seen as solution to the non-linear Fokker-Planck equation (1.8) related to (1.1) and a weak uniqueness criterion à la Krylov-Röckner. Strong well-posedness is next derived from a classical pathwise uniqueness result, see Krylov-Röckner [32] for the Brownian case and Xie-Zhang [61] for the pure jump case.

We present in Section 2 the useful properties of Besov spaces that will be used in our analysis. The framework of Besov interaction kernels allows to revisit the martingale approach to well-posedness for McKean-Vlasov models in a quite systematic way starting from some (seemingly) sharp global density
estimates, valid for any initial law \( \mu \). Section 3.1 is dedicated to this step, and Section 3.2 to the derivation of the well-posedness results (in a weak and/or strong sense). Some technical results are presented in the Appendix.

1.2. Main results. From now on, in the pure jump case \( \alpha \in (1, 2) \), we assume that the driving process \( W \) in (1.1) satisfies the following condition:

**Assumption (UE).** The Lévy measure \( \nu \) of \( W \) is given by the decomposition \( \nu(dz) = w(d\xi)/\rho^{1+\alpha} \mathbb{E}_{(\rho>0)} dp \) where \( w \) is a symmetric measure on the unit sphere \( S^{d-1} \) which satisfies the uniform non-degeneracy condition:

\[
\kappa^{-1}|\lambda|^\alpha \leq \int_{S^{d-1}} |\xi \cdot \lambda| w(d\xi) \leq \kappa |\lambda|^\alpha, \quad \text{for all } \lambda \in \mathbb{R}^d,
\]

for some \( \kappa \geq 1 \). In particular, since we here consider an additive noise, its Lévy measure can actually have a singular spherical part (cylindrical processes are allowed).

**Theorem 1.** Fix \( T > 0 \) and \( t \in [0, T) \). Let \( b \) in (1.1) belong to \( L^r((t, T], B^\beta_{p,q}([0, T])) \) and let the parameters satisfy the condition

\[
\beta > 1 - \alpha + \frac{d}{p} + \frac{\alpha}{r}. \tag{C0}
\]

Then, for any initial law \( \mu \in \mathcal{P}(\mathbb{R}^d) \), the McKean-Vlasov SDE (1.1) admits a weak solution s.t. its marginal laws \( \mu_{t}(dy) \) have a density for almost any time, i.e. for almost all \( r \in (t, T] \), \( \mu_{t}(dy) = \nu_{t}(y, dy) \), which satisfies:

\[
\int_{t}^{T} ds |\nu_{t}(s, \cdot)|^\beta_{p,q} < +\infty,
\]

for any \( r \in [r', (-\beta/\alpha + d/(op))^{-1}] \) where \( p^{-1} + (p')^{-1} = q^{-1} + (q')^{-1} = r^{-1} + (r')^{-1} = 1 \). Moreover, the solution is unique among all the weak solutions that satisfy the above properties.

The above well-posedness result moreover holds in a strong sense if the driving process is rotationally invariant and the parameters satisfy the following more stringent (when \( \alpha \neq 2 \)) condition:

\[
\beta > 2 - \frac{3}{2} \alpha + \frac{d}{p} + \frac{\alpha}{r}. \tag{C0s}
\]

**Remark 2 (About the strong uniqueness).** In the above theorem we assume for strong uniqueness that \( W \) is rotationally invariant. This is of course the case for \( \alpha = 2 \) but it actually means that in the pure jump case we restrict the noise to the isotropic stable process for \( W \). This is mainly due to the fact that to establish the result, we apply a uniqueness criterion due to Xie and Zhang, see [31], where a driving isotropic process is considered in order to deal more easily with a multiplicative noise and related heat kernel estimates. While clearly restrictive, we actually believe that in the current additive framework, the PDE analysis of the indicated reference could be adapted and that the strong uniqueness result should hold under the condition \( \beta_{p,q} \) for any symmetric stable driving process satisfying Assumption (UE) (including e.g. symmetric cylindrical processes).

Observe finally that for \( \alpha = 2 \) the conditions (C0) and (C0s) for weak and strong uniqueness coincide.

1.3. Strategy of proof. As explained before, the construction of a weak solution to (1.1) proceeds hereafter from a regularization procedure and a stability argument. When doing so, we will use the following approximation result whose proof, which relies on the preliminaries set in Section 2, is postponed to the Appendix.

**Proposition 2 (Smooth approximation of the drift and associated convergence properties).** Let \( b \in L^r((t, T], B^\beta_{p,q}) \) and \( \beta \in (-1, 0] \), \( 1 \leq p, q \leq \infty \). There exists a sequence of time-space smooth bounded functions \( (\tilde{b}^\varepsilon)_{\varepsilon>0} \) s.t.

\[
|b - \tilde{b}^\varepsilon|_{L^r((t, T], B^\beta_{p,q})} \rightarrow 0, \quad \forall \beta < \beta,
\]

with \( \tilde{r} = r \) if \( r < +\infty \) and for any \( \tilde{r} < +\infty \) if \( r = +\infty \). Moreover, there exists \( \varepsilon \geq 1 \), \( \sup_{\varepsilon>0} |b^\varepsilon|_{L^r((t, T], B^\beta_{p,q})} \leq c|b|_{L^r((t, T], B^\beta_{p,q})}$. 

From the specific convolution structure of the non-linear drift, we now introduce, for any measure $\nu$ on $\mathbb{R}^d$ for which this is meaningful, the notation:

$$B_\nu(s, \cdot) := b(s, \cdot) * \nu(\cdot) = \int_{\mathbb{R}^d} b(s, \cdot - y) \nu(dy).$$

We now write similarly, for all $\varepsilon > 0$

$$B^\varepsilon(s, \cdot) := b^\varepsilon(s, \cdot) * \nu(\cdot),$$

(1.12)

which is well defined for any $\nu \in \mathcal{P}(\mathbb{R}^d)$, regardless of the Besov space where $b$ belongs to, since $b^\varepsilon$ is smooth and bounded. This allows to introduce in turn the following mollified version of (1.1):

$$X^{\varepsilon, t, \xi}_s = \xi + \int_t^s B^\varepsilon_{\mu^\varepsilon_t}(r, X^{\varepsilon, t, \xi}_r)dr + \mathcal{W}_s - \mathcal{W}_t, \quad \mu^\varepsilon_t(s, \cdot) = \text{Law}(X^{\varepsilon, t, \xi}_s), \quad s \in (t, T],$$

(1.13)

which is strongly (and thus weakly) well-posed for any $\varepsilon > 0$, see Frieha, Konakov and Menozzi [39] for $\alpha \in (1, 2)$ or Sznitman [56] in the Brownian case. We emphasize that, due to weak uniqueness, $\mu^\varepsilon_t(s, \cdot)$ only depends on the law $\mu$ of the random initial condition $\xi$.

Let us now prove that the marginal laws of the unique weak solution of this regularized McKean-Vlasov SDE are absolutely continuous w.r.t. the Lebesgue measure. Consider the associated decoupled flow, that is the linear SDE parametrized by the flow of measure $(\mu^\varepsilon_t)_{t \in [0, T]}$ which writes

$$\dot{X}^{\varepsilon, t, \xi}_s = x + \int_t^s B^\varepsilon_{\mu^\varepsilon_t}(v, X^{\varepsilon, t, \xi}_r)dr + \mathcal{W}_s - \mathcal{W}_t, \quad x \in \mathbb{R}^d.$$  

(1.14)

Again, for every $\varepsilon > 0$, this linear SDE admits a unique weak solution. We denote its marginal laws by $(\tilde{\mu}^\varepsilon_{t,x})_{t \in [0, T]}$. Note importantly that, as $\mu^\varepsilon_t$ and $\tilde{\mu}^\varepsilon_{t,x}$ are uniquely determined, the following key relation holds: for all $A$ in $\mathcal{B}([t, T]) \otimes \mathcal{B}(\mathbb{R}^d)$, $\mu^\varepsilon_t(A) = (\int_t^T dr \int \mathbb{1}_{A} \tilde{\mu}^\varepsilon_{t,r}(dy)\mu(dx))$. It is now worth noticing that in the mollified setting the drift in equation (1.14) is smooth in the time and space variables and bounded. Indeed, for all $y \in \mathbb{R}^d$

$$|B^\varepsilon_{\mu^\varepsilon_t}(r, y)| \leq |b^\varepsilon|_\infty \int_{\mathbb{R}^d} \mu^\varepsilon_{t,r}(dz) = |b^\varepsilon|_\infty,$$

and the controls for the derivatives could be derived similarly differentiating $b^\varepsilon$. This is what allows to derive from Friedman [29] for $\alpha = 2$ and Bichteler et al. [5] in the pure jump case that the SDE admits for any $s \in (t, T]$ a smooth density (we could also refer to [49] in the rotationally invariant case). Thus, the law $\tilde{\mu}^\varepsilon_{t,x}$ is absolutely continuous w.r.t. the Lebesgue measure with density $\tilde{\rho}^\varepsilon_{t,x}(r, \cdot)$. Hence, there exists $\tilde{\rho}^\varepsilon_{t,r}$ such that:

$$\forall A \in \mathcal{B}([t, T]) \otimes \mathcal{B}(\mathbb{R}^d), \quad \mu^\varepsilon_t(A) = \int_A \int_p \tilde{\rho}^\varepsilon_{t,r}(v, y)\mu(dx)dydy =: \int_A \rho^\varepsilon_{t,r}(v, y)dydy,$$

(1.15)

i.e. $\mu^\varepsilon_t$ is absolutely continuous as well. We emphasize that the relation (1.15) holds for any $\alpha \in (1, 2]$.

We now state a result, which will be at the starting point of our analysis and whose proof is postponed to Appendix [3] for the sake of simplicity.

**Lemma 3** (Duhamel representation for the time marginal laws of the process with mollified interaction kernel). The following Duhamel representation holds for the solution of equation (1.13). For each $\varepsilon > 0$, $\tilde{\rho}^\varepsilon_{t,r}$ satisfies for all $s \in (t, T]$ and all $y \in \mathbb{R}^d$:

$$\tilde{\rho}^\varepsilon_{t,r}(s, y) = \tilde{\rho}^\varepsilon_{s-t}(y) - \int_t^s dv \left[ \left( B^\varepsilon_{\mu^\varepsilon_t}(v, \cdot) \rho^\varepsilon_{s-t}(v, \cdot) \right) * \nabla \rho^\varepsilon_{s-t}(v, \cdot) \right](y),$$

(1.16)

where $p^\alpha$ stands for the density of the driving process $\mathcal{W}$, and with a slight abuse of notation w.r.t. (1.12), $B^\varepsilon_{\tilde{\mu}^\varepsilon_t}(v, \cdot) = [b^\varepsilon(v, \cdot) * \tilde{\rho}^\varepsilon_{t,r}(v, \cdot)]$.

We will actually prove (see Lemma 4) that there exists a constant $C > 0$, s.t. for any $\varepsilon > 0$, and $p, q, r, \beta$ satisfying condition (C0) (see Theorem 1):

$$|\tilde{\rho}^\varepsilon_{t,r}|_{L^p((t,T), B^{\beta}_{q',\rho'})} \leq C(T-t)^{\theta}, \quad \theta > 0.$$
It is furthermore clear that for any \( \varepsilon > 0 \), \( \rho^\varepsilon_{t,x} \) solves, in the distributional sense, the equation:
\[
\begin{align*}
\partial_s \rho^\varepsilon_{t,x}(s,y) + \text{div}(B^\varepsilon_{x,y}(s,y)\rho^\varepsilon_{t,x}(s,y)) - L^\alpha \rho^\varepsilon_{t,x}(s,y) &= 0, \\
\rho^\varepsilon_{t,x}(t,\cdot) &= \mu,
\end{align*}
\]
or equivalently, for all \( \varphi \in C^\infty_0((-T,T) \times \mathbb{R}^d) \) (up to a possible symmetrization for \( s < t \) and with \( C^\infty_0((-T,T) \times \mathbb{R}^d) \) standing for the set of real valued infinitely differentiable functions with compact support in \((-T,T) \times \mathbb{R}^d)\),
\[
\begin{align*}
- \int \varphi(t,y)\mu(dy) &- \int_t^T ds \int_{\mathbb{R}^d} \text{div}(B^\varepsilon_{x,y}(s,y)\rho^\varepsilon_{t,x}(s,y)) \cdot \nabla \varphi(s,y) \\
&+ \int_t^T ds \int_{\mathbb{R}^d} dy \rho^\varepsilon_{t,x}(s,y)(-\partial_s + (L^\alpha)^*)\varphi(s,y) = 0,
\end{align*}
\]
where \((L^\alpha)^*\) stands for the adjoint of \(L^\alpha\). The driving process \( \mathcal{W}\) being symmetric, then \((L^\alpha)^* = L^\alpha\).

Provided that \( \rho^\varepsilon_{t,x}\) admits a limit \( \rho_{t,x}\) in some appropriate function space (see Lemma 8 below) - which precisely allows to take the limit in the Duhamel formulation (1.16) - we derive that the limit satisfies (Lemma 11)
\[
\rho_{t,x}(s,y) = \rho^\varepsilon_{s-t}(y(\cdot) - \int_t^s dv \left\{ [\rho_{t,x}(v,\cdot) B_{t,x}^\alpha(v,\cdot)] \ast \nabla \rho_{s-v}^\varepsilon \right\}(y),
\]
i.e. is a mild solution to the non-linear Fokker-Planck equation related to (1.1). By extension \( \rho_{t,x}(s,y)\) dy also provides a distributional solution to the non-linear Fokker-Planck equation related to (1.1):
\[
- \int \varphi(t,y)\mu(dy) - \int_t^T ds \int_{\mathbb{R}^d} dy \left( B_{t,x}^\alpha(s,y)\rho_{t,x}(s,y) \right) \cdot \nabla \varphi(s,y) \\
+ \int_t^T ds \int_{\mathbb{R}^d} dy \rho_{t,x}(s,y)(-\partial_s + (L^\alpha)^*)\varphi(s,y) = 0, \quad \varphi \in C^\infty_0((-T,T) \times \mathbb{R}^d).
\]
(1.19)

This provides a sufficient (and necessary) basis to construct a solution to (1.1) identifying it as the limit of the martingale problem related with (1.18). More precisely, from the solution to (1.18), one can consider for each \( \varepsilon > 0 \) the probability measure \( \mathbb{P}^\varepsilon\) on the space \( \Omega_\alpha\) (where \( \Omega_\alpha\) stands for the space of càdlàg functions \( \mathbb{D}(\left[ t,T \right]\; [\mathbb{R}^d])\) if \( \alpha \in \{1,2\} \) and the space of continuous functions \( C([t,T];\mathbb{R}^d)\) otherwise) such that, for \( x(s)\), \( t \leq s \leq T\), the canonical process on \( \Omega_\alpha\), and for \( \mathbb{P}^\varepsilon_t(x,dx) := \mathbb{P}^\varepsilon_t(x(s) \in dx)\) the family of probability measures induced by \( x(s)\), we have: the initial measure \( \mathbb{P}^\varepsilon_t(t,\cdot)\) is equal to \( \mu\) and for all function \( \phi\) twice continuously differentiable on \( \mathbb{R}^d\), with bounded derivatives at all order, the process
\[
\phi(x(s)) - \phi(x(t)) - \int_t^s dv \left\{ B_{t,x}^\alpha(v,\mu) \cdot \nabla \phi(x(v)) + L^\alpha(\phi(x(v))) \right\} \] 
\( dv, \quad t \leq s \leq T, \)
is a martingale. Provided, again, that for any \( \varepsilon > 0 \) the marginal distributions \( \mathbb{P}^\varepsilon_t(s, dx) = \rho^\varepsilon_{t,x}(s,x)\) dx lie in a appropriate space to ensure that \( (\mathbb{P}^\varepsilon_t)_{t > 0} \) is compact in \( \mathcal{P}(\Omega_\alpha)\) any corresponding limit along a converging subsequence defines naturally a solution to the (non-linear) martingale problem related to (1.1). From the well-posedness of the limit Fokker-Planck equation one eventually derives uniqueness results for the marginal laws giving in turn the uniqueness of the martingale solution associated with (1.1).

Also, the regularity properties of the time-marginals of the limit non-linear Fokker-Planck equation, (inherited from Lemma 7 below), allow to regularize the distributional interaction kernel so that the non-linear drift \( B_{\rho_{t,x}} \) is actually a function living in some Lebesgue space (in time and space). This permits to give a meaning to the dynamics in (1.1) by connecting martingale and weak solutions through classical arguments. All these properties are gathered in Propositions 12 and 13.

Furthermore, when slightly reinforcing (C9) to (C05), we are able to obtain better estimates (namely in suitable Lebesgue-Besov space - with positive regularity index for the latter) on the non-linear drift \( B_{\rho_{t,x}}\) which allows to derive, in turn, a strong well-posedness result by viewing the McKean-Vlasov SDEs as a linear SDE parametrized by the unique weak solution and applying results of [42] in the Brownian
case and, as highlighted previously, in the pure jump one for rotationally invariant processes (see Proposition 15 below).

1.4. Notations. For any real $\ell \in [1, \infty]$, we denote by $\ell'$ its conjugate i.e. $\ell'$ is such that $1/\ell + 1/\ell' = 1$. When there are no ambiguities, we will often omit to mention the spatial argument when specifying a function space, i.e. we write $L^\ell(R^d) = L^\ell$. We will use below the notation $C$ for a generic constant that might change from line to line but only depends on known parameters appearing in (C0).

2. Besov spaces and associated tools.

2.1. Reminders on Besov spaces. We recall that the space $B^\gamma_{\ell,m}(\mathbb{R}^d, \mathbb{R}^k)$, $k \in \{1, d\}$, $\ell, m, \gamma \in \mathbb{R}$ is usually defined through the dyadic Littlewood-Paley decomposition (see e.g. [44] or [3]). Namely, it consists in the elements of $S'(\mathbb{R}^d, \mathbb{R}^k)$ (where $S(\mathbb{R}^d, \mathbb{R}^k)$ stands for the Schwartz space) such that the quantity

$$|f|_{B^\gamma_{\ell,m}, \mathbb{L}^p} := |F^{-1}(\phi F(f))|_{L^\ell} = \left(\sum_{j \in \mathbb{N}} 2^{\gamma jm} |F^{-1}(\phi_j F(f))|_{L^\ell}^m \right)^{1/m}$$

is finite where $\phi \in C_0^\infty(\mathbb{R}^d, \mathbb{R})$ s.t. $\phi(0) \neq 0$, $\phi_j(y) = 2^j \phi(2^j y)$ and $F$, $F^{-1}$ respectively denote the Fourier and inverse Fourier transform. This quantity also defines a norm for which $B^\gamma_{\ell,m}(\mathbb{R}^d, \mathbb{R}^k)$ is a Banach space - see e.g. Triebel [57], Theorem 2.3.3., p. 48. Instead of the Littlewood-Paley decomposition inducing the norm $| \cdot |_{B^\gamma_{\ell,m}, \mathbb{L}^p}$, we will now on use the so-called thermic characterization of Besov spaces which involves an underlying heat kernel. The thermic characterization is presented in Section 2.6.4 of [57] for the Gaussian and Cauchy heat kernel (corresponding respectively to $\alpha = 2$ and $\alpha = 1$).

However, one can also derive (from Theorem 1 in Section 2.5.1 of the same reference) that

$$|f|_{B^\gamma_{\ell,m}, \mathbb{L}^p} = \left(\int_0^1 \frac{dv}{v} (n - \gamma / \tilde{\alpha})^m |\partial_\theta^m \tilde{p}^\alpha(v, \cdot) * f|_{L^\ell}^m \right)^{1/m}$$

for $1 \leq m < \infty$,

$$\sup_{v \in (0, 1]} \left\{ v^{(n - \gamma / \tilde{\alpha})} |\partial_\theta^m \tilde{p}^\alpha(v, \cdot) * f|_{L^\ell} \right\}$$

for $m = \infty$,

$$|f|_{H^\gamma_{\ell,m}, \tilde{\alpha}} := |F^{-1}(\phi F(f))|_{L^\ell} + \left(\int_0^1 \frac{dv}{v} (n - \gamma / \tilde{\alpha})^m |\partial_\theta^m \tilde{p}^\alpha(v, \cdot) * f|_{L^\ell}^m \right)^{1/m}$$

for $1 \leq m < \infty$,

$$\sup_{v \in (0, 1]} \left\{ v^{(n - \gamma / \tilde{\alpha})} |\partial_\theta^m \tilde{p}^\alpha(v, \cdot) * f|_{L^\ell} \right\}$$

for $m = \infty$. The choice of the parameter $\tilde{\alpha} \in [1, 2]$ is for free, $n$ being any non-negative integer (strictly) greater than $\gamma / \tilde{\alpha}$, the function $\phi$ is as above, and $\tilde{p}^\alpha(v, \cdot)$ denoting the density function at time $v$ of the $d$-dimensional isotropic $\tilde{\alpha}$-stable process. From now on, we will set $\tilde{\alpha} = \alpha$, i.e. we take for the thermic characterization the same stability index as the driving noise.

The current choice of the thermic kernel is rather natural in our framework. Since we will establish a priori estimates on Duhamel type representations which involve the density $p^\alpha$ of the stable driving noise (see again [1.15] and [1.19]), the previous thermic characterization allows to benefit from stability and scaling properties in the associated convolutions. This characterization of Besov spaces was already used in [20] for similar reasons. The quantity in (2.1) also induces a norm, equivalent to $| \cdot |_{B^\gamma_{\ell,m}, \mathbb{L}^p}$, and for the remaining of the paper we will denote for $f \in B^\gamma_{\ell,m}$:

$$|f|_{B^\gamma_{\ell,m}} := |f|_{H^\gamma_{\ell,m}, \tilde{\alpha}}.$$ 

We will refer to the contribution $T^\gamma_{\ell,m}(f) =: T^\gamma_{\ell,m}(f)$ in (2.1) as the thermic part of the norm.

2.2. Properties of Besov spaces. We recall here some key technical results on Besov spaces and their embeddings,
(i) **Continuous embedding.** With Lebesgue spaces ([53 Prop. 2.1]):
\[
\forall 1 \leq \ell \leq \infty, \quad B_{\ell,1}^0 \hookrightarrow L^\ell \hookrightarrow B_{\ell,\infty}^0.
\]  
(\text{E}_1)

Between Besov spaces (see (1.1) in [59] and Proposition 2.2 in [53]):
\[
B_{p_0,q_0}^s \hookrightarrow B_{p_1,q_1}^s \quad \text{for } p_0,p_1,q_0,q_1 \in [1,\infty], \quad q_0 \leq q_1, \quad p_0 \leq p_1 \text{ such that } s_0 - d/p_0 \geq s_1 - d/p_1.
\]  
(\text{E}_2)

We refer to Sections 4.1 and 4.2 in [53] for additional embeddings.

(ii) **Young (or convolution) inequality.** Let \( \gamma \in \mathbb{R}, \ell, m \in [1,\infty] \). Then for any \( \delta \in \mathbb{R}, \ell_1, \ell_2 \in [1,\infty] \) such that \( 1 + \ell^{-1} = \ell_1^{-1} + \ell_2^{-2} \) and \( \gamma, m, m_2 \in (0,\infty) \) such that \( m^{-1}_1 \geq (m^{-1} - m_2^{-1})^\vee 0 \)
\[
|f \ast g|_{B_{\ell_1,m_1}^\gamma} \leq c_{\gamma, m_1} |f|_{B_{\ell_2,m_2}^\gamma} |g|_{B_{\ell_2,m_2}^\gamma},
\]  
(\text{Y})

for \( c_{\gamma} > 0 \) a universal constant depending only on \( d \). The initial proof of this inequality can be found in [9] Theorem 3, see also [13] for recent convolution inequalities for Besov and Triebel-Lizorkin spaces.

(iii) **Besov norm of heat kernel (see [29] Lemma 11).** There exists \( c_{\text{HK}} := C(\alpha,\ell, m, \gamma, d) > 0 \) s.t. for all multi-index \( a \in \mathbb{N}^d \) with \( |a| \leq 1, \) and \( 0 < v < \infty \):
\[
|\partial^a \rho_{\alpha,v}|_{B_{\ell_1,m_1}^\gamma} \leq c_{\text{HK}} \quad \text{for } \quad (s-v)\gamma + (1-\gamma)(d-v).
\]  
(\text{HK})

(iv) **Duality inequality (see e.g. [44 Proposition 3.6]).** For \( \ell, m \in [1,\infty], \gamma \in \mathbb{R} \) and \( (f,g) \in B_{\ell,m}^\gamma \times B_{\ell,m}^{-\gamma} \), it holds:
\[
|\int f(y)g(y)dy| \leq |f|_{B_{\ell,m}^\gamma} |g|_{B_{\ell,m}^{-\gamma}}.
\]  
(\text{D})

2.3. A convolution Lemma in Besov spaces. As an immediate consequence of the above technical results, we have the following Lemma.

**Lemma 4.** Let \( f, g_1, g_2 \) be in \( B_{\ell,f,m_1}, B_{\ell,g_1,m_1}^{-\gamma}, L^{s_2} \) respectively where \( \gamma_f \) is in \([1,\infty]\), \( \ell_f, \ell_{g_1}, \ell_{g_2} \) in \([\ell_0,\infty]\) and \( m_f, m_{g_1}, m_{g_2} \) in \([1,\infty]\).

For any \( \ell, \ell_1, \ell_2, m, m_1, m_2 \) in \([1,\infty]\) satisfying
\[
(\ell_f)^{-1} + (\ell_{g_1})^{-1} + (\ell_{g_2})^{-1} = 2 + \ell^{-1}, \quad m_1 \leq m, \quad m_2^{-1} \geq (1 - m_1^{-1}) \vee 0,
\]  
(2.2)

and any \( \gamma \geq 0 \) s.t. \( h \in B_{\ell,h,m}^\gamma \), denoting \( \mathcal{C} := f \ast g_1 \), there exists \( c_{\text{ev}} \geq 1 \) such that
\[
|\mathcal{C} \ast h|_{B_{\ell,m}^\gamma} \leq c_{\text{ev}} |f|_{B_{\ell,m}^\gamma} |g_1|_{B_{\ell_1,m_1}^{-\gamma}} |g_2|_{L^{s_2}} |h|_{B_{\ell_1,m_1}^{-\gamma}}.
\]  
(2.3)

Before proving the above result we point out that it will be crucial in the analysis of the non-linear drift term in the Duhamel formulations ([14,16]) (with mollified coefficients) and [14,18] (the related limit equation) in order to obtain a priori estimates. Roughly speaking, in the proof of Lemma 7 we will apply the above lemma with \( \mathcal{C} = B_{\rho_{\gamma,v}}^\gamma (v, \cdot) \cdot \) corresponding to the case \( f = b^\gamma(v, \cdot), g_1 = \rho_{\gamma,v}^\gamma (v, \cdot), \) \( g_2 = \rho_{\gamma,v}^\gamma (v, \cdot) \cdot \) and \( h = \nabla \rho_{\gamma,v}^\gamma \) in the mollified setting and with the same entries without the superscripts in \( \varepsilon \) in the limit one.

**Proof.** Apply first the Young inequality (\text{Y}) to obtain
\[
|(\mathcal{C} \ast h)|_{B_{\ell,m}^\gamma} \leq c_{\gamma} |\mathcal{C} \ast h|_{B_{\ell,m}^\gamma} |h|_{B_{\ell,m}^\gamma},
\]  
for any \( 1 + \ell^{-1} = (\ell_f)^{-1} + (\ell_h)^{-1} \) and \( m \geq m_1 \). Note now that, applying first the continuous embedding (\text{E}_1), then the Hölder inequality and next the continuous embedding (\text{E}_1) again gives
\[
|\mathcal{C} \ast h|_{B_{\ell,m}^\gamma} \leq C |\mathcal{C} \ast g_1|_{L^{s_2}} \leq C |\mathcal{C} \ast g_1|_{L^{s_2}} |g_2|_{L^{s_2}} \leq C |\mathcal{C} \ast g_1|_{L^{s_2}} |g_2|_{L^{s_2}},
\]  
for any \( (\ell_f)^{-1} + (\ell_{g_1})^{-1} = (\ell_{g_2})^{-1} \). Combining this last integrability condition with the previous one arising from the convolution inequality yields
\[
1 + \ell^{-1} = (\ell_f)^{-1} + (\ell_{g_1})^{-1} + (\ell_h)^{-1}.
\]  
(2.4)

Moreover, applying one more time the Young inequality (\text{Y}) gives
\[
|\mathcal{C} \ast g_1|_{B_{\ell,m}^\gamma} = |f \ast g_1|_{B_{\ell,m}^\gamma} \leq c_{\gamma} |g_1|_{B_{\ell_1,m_1}^{-\gamma}} |f|_{B_{\ell_1,m_1}^{-\gamma}},
\]  
(2.5)
with \((\ell_{g1})^{-1} + (\ell_{f})^{-1} = 1 + (\ell_{g})^{-1}\) and any \(m_{g1}^{-1} \geq (1 - m_{f}^{-1}) \lor 0\). Bringing together the above estimates yields
\[
|f_{\varepsilon}g_{2} \ast h|_{B_{\ell,m}^{\gamma}} \leq c_{\varepsilon}v|f|_{B_{\ell,m}^{\gamma}}g_{1}|_{B_{\ell_{g1},m_{g1}}^{\gamma}}|g_{2}|_{L^{\infty}}|h|_{B_{\ell_{h},m_{h}}^{\gamma}},
\]
for any \((\ell_{f})^{-1} + (\ell_{g1})^{-1} + (\ell_{g2})^{-1} + (\ell_{h})^{-1} = 2 + \ell^{-1}, m_{h} \leq m, m_{g1}^{-1} \geq (1 - m_{f}^{-1}) \lor 0\), in view of \((2.4)\).

2.4. On the embedding of \(P(\mathbb{R}^{d})\) into Besov spaces. We give here the following Lemma which specifies how the set of probability measures on \(\mathbb{R}^{d}\) can be embedded in an intersection of Besov spaces.

**Lemma 5.** \(P(\mathbb{R}^{d})\) is a subset of \(\cap_{\ell \geq 1} B_{\ell,\infty}^{-d/\ell'}\) and \(\cap_{\ell \geq 1} B_{\ell,m}^{-d/\ell' - \varepsilon}\), for \(\varepsilon > 0, m \in [1, \infty)\) and \(\ell \in [1, \infty]\).

**Proof.** Let \(\nu\) be an arbitrary probability measure on \(\mathbb{R}^{d}\). For any \(\ell \in [1, \infty), \phi \in C_{0}^{\infty}(\mathbb{R}^{d}, \mathbb{R}), \phi(0) \neq 0\) (as in Section 2.1),
\[
|F^{-1}(\phi F(\nu))|_{L^{\infty}} = |F^{-1}(\phi) \ast \nu|_{L^{\infty}} = \left( \int_{\mathbb{R}^{d}} dx \left| F^{-1}(\phi) \ast \nu(x) \right|^{\ell} \right)^{\frac{1}{\ell}} = \left( \int_{\mathbb{R}^{d}} dx \int_{\mathbb{R}^{d}} \left| F^{-1}(\phi)(x - y) \nu(dy) \right|^{\ell} \right)^{\frac{1}{\ell}} \leq \left( \int_{\mathbb{R}^{d}} dx \int_{\mathbb{R}^{d}} \left| F^{-1}(\phi)(x - y) \right|^{\ell} \nu(dy) \right)^{\frac{1}{\ell}} = |F^{-1}(\phi)|_{L^{\infty}},
\]
using classical convexity inequalities and the Fubini theorem as well as the fact that, since \(\phi \in C_{0}^{\infty}, F^{-1}(\phi) \in \mathcal{S}\) for the last inequality. If now \(\ell = \infty\), one readily gets:
\[
|F^{-1}(\phi F(\nu))|_{L^{\infty}} = |F^{-1}(\phi) \ast \nu|_{L^{\infty}} \leq |F^{-1}(\phi)|_{L^{\infty}} < +\infty.
\]
Let now consider \(\gamma \leq 0\) and, with the terminology of Section 2.1, the thermic part \(T_{\ell,m}^{\gamma}(\nu)\) of \(|\nu|_{B_{\ell,m}^{\gamma}}\).

For this choice, from \((2.1)\), we can take \(n = 0\) and write then - similarly to the previous computations (replacing actually \(F^{-1}(\phi)\) by \(\tilde{p}(v, \cdot)\) and according to \([\text{HK}]\) and \([\text{E}^{\ell}]\) - for any \(\ell \in [1, +\infty], T_{\ell,\infty}^{\gamma}(\nu) := \sup_{v \in (0,1]} v^{-\frac{\gamma}{\ell}}|\tilde{p}(v, \cdot) \ast \nu|_{L^{\infty}} \leq \sup_{v \in (0,1]} v^{-\frac{\gamma}{\ell}}|\tilde{p}(v, \cdot)|_{L^{\infty}} \leq C \sup_{v \in (0,1]} v^{-\frac{\gamma}{\ell} + \frac{\gamma}{d/\ell'}} < +\infty,\]
whenever \(0 \leq -\gamma - d/\ell' \iff \gamma \leq -d/\ell'\). On the other hand, for \(m \in [1, +\infty), T_{\ell,m}^{\gamma}(\nu) < +\infty\) whenever \(-\gamma - d/\ell' > 0\). This gives the claim. \(\square\)

2.5. Some useful weighted spaces. In the following we will also frequently use weighted Lebesgue spaces in the time variable with arguments valued in Besov spaces. Namely, for \(\gamma \in \mathbb{R}_{+}, \ell, m, r \in [1, \infty]\) we introduce, for \(0 \leq t < S \leq T\), the Bochner space:
\[
L_{r}^{\gamma}((t,S], B_{\ell,m}^{\gamma}) := \left\{ f : s \in [t,S] \mapsto f(s, \cdot) \in B_{\ell,m}^{\gamma} \text{ measurable and s.t. } \int_{t}^{S} ds (S - s)^{-\frac{\gamma}{r}} |f(s, \cdot)|_{B_{\ell,m}^{\gamma}}^{r} < \infty \right\},
\]
(2.6)
equipped with its natural norm:
\[
|f|_{L_{r}^{\gamma}((t,S], B_{\ell,m}^{\gamma})} := \left( \int_{t}^{S} ds (S - s)^{-\frac{\gamma}{r}} |f(s, \cdot)|_{B_{\ell,m}^{\gamma}}^{r} \right)^{\frac{1}{r}}.
\]
This space turns out to be a Banach space for the chosen weight \(s \in [t,S] \mapsto (S - s)^{-r/\alpha}\) as well as for a rather large class of weights (see e.g. [33] Chapter 1). It can be pointed out that the above weight depends strongly on the right hand limit of the time interval. The choice of making this dependency implicit in the notation of the norm \(|\cdot|_{L_{r}^{\gamma}((t,S], B_{\ell,m}^{\gamma})}\) is performed in order to lighten forthcoming computations.
3. Proof of Theorem 1

In the whole section, we might assume for some results that the time-horizon $T > 0$ is small enough, i.e. smaller than some positive time depending only on the parameters $\alpha, \beta, p, r, d$. This is somehow required to derive the a priori estimates (see Lemma 4) needed to obtain well-posedness of the non-linear Fokker-Planck equation. This leads to an a priori restriction of the time interval $[t, T]$ which is nevertheless just provisional: as a priori estimates will require nothing else on the initial condition but being a probability measure, and will depend smoothly on the time interval size, they can then be iterated up to an arbitrary time-horizon $T$.

3.1. The corresponding non-linear Fokker-Planck equation. We here prove the following Proposition which roughly states that for any initial condition being a probability measure, the non-linear Fokker-Planck equation admits a unique solution in a suitable Lebesgue-Besov space, for a certain range of parameters. More specifically, the range of the parameters allows to quantify: on the one hand, how much the Besov norm of the solution is integrable; on the other hand, how much the local regularity of parameters. More specifically, the range of the parameters allows to quantify: on the one hand, how much the Besov norm of the solution is integrable; on the other hand, how much the local regularity of the Besov norm can be improved in term of the gap $\Gamma$ in (G):

$$\Gamma := \beta - \left(1 - \frac{\alpha}{p} + \frac{d}{\rho} + \frac{\alpha}{r}\right) > 0.$$

Proposition 6. Assume that the parameters are such that (C0) holds. Then, for any $(t, \mu)$ in $[0, T] \times \mathcal{P}(\mathbb{R}^d)$, the non-linear Fokker-Planck equation (1.19) admits a solution which is unique among all the distributional solutions lying in $L^T(B_{p, r}^{\rho, \bar{\rho} \Gamma})$ where

$$\mathbf{r} \in \left[\bar{r}', \left(\frac{1}{\alpha} \left(-\beta + \bar{\rho} \Gamma + \frac{d}{\rho}\right)\right)^{-1}\right], \forall \theta \in [0, 1). \quad (3.1)$$

Moreover, for all $s \in [t, T]$, $\mathbf{r}_{t, \mu}(s, \cdot)$ belongs to $\mathcal{P}(\mathbb{R}^d)$. Eventually, for a.e. $s$ in $(t, T)$, $\mathbf{r}_{t, \mu}(s, \cdot)$ is absolutely continuous w.r.t. the Lebesgue measure and satisfies the Duhamel representation (1.18).

The preliminary step to prove the previous well-posedness result for the non-linear Fokker-Planck equation consists in establishing suitable a priori estimates, in the corresponding function space, for the mollified equation (1.16). This is the point of the next Lemma in which we use what we call a dequantification approach (see eq. (3.7) below and explanations there). We then proceed with a Lemma that gives that for any decreasing sequence $(\varepsilon_k)_k$ going to 0, $(\mathbf{r}_{t, \mu})_k$ is a Cauchy sequence in some appropriate function space (Lemma 5 below). We then conclude that the limit of the previous convergent sequence solves the non-linear Fokker Planck equation (1.19) (Lemma 9) in a distributional sense. We eventually prove, through a rigorous derivation of the Duhamel formulation (1.18), that this solution is unique among all the solutions lying in the corresponding function space (Lemma 10). This procedure completes the proof of Proposition 6.

In the following, it is always assumed that the parameters are such that (C0) holds.

Lemma 7. For any $(t, \mu)$ in $[0, T] \times \mathcal{P}(\mathbb{R}^d)$, for any $\theta \in [0, 1)$, any $\bar{r}$ satisfying (S.1) there exist $C := C(d, \alpha, \beta, p, \vartheta) > 0$ and $\theta := \theta(d, \alpha, \beta, p, \vartheta) > 0$ such that it holds

$$\forall \in > 0, \quad \int_t^T ds |\mathbf{r}_{t, \mu}(s, \cdot)|_{B_{p', \rho'}^{\beta + \vartheta \bar{r}}} \leq C(T - t)^\theta,$$

and for any $t < S < T$ with the notations of (2.6), for $\bar{r}' \in \left[\bar{r}', \left(\frac{1}{\alpha} \left(-\beta + \bar{\rho} \Gamma + \frac{d}{\rho} + 1\right)\right)^{-1}\right]$, for some $\delta := \delta(\bar{r}') > 0$.

$$\forall \in > 0, \quad |\mathbf{r}_{t, \mu}(t, S)|_{B_{p', \rho'}^{\beta + \vartheta \bar{r}'}} \leq C(S - t)^{\frac{\delta}{\bar{r}'}}, \quad (3.2)$$

for some $\delta := \delta(\bar{r}') > 0$. 
Proof of Lemma 7. For the mollified equation, from the Duhamel representation, we have for any $\ell, m \in [1, \infty]$,

$$|\tilde{\rho}_{t,\mu}^\epsilon(s, \cdot)|_{B^{\gamma + \theta \Gamma}_{\ell,m}} \leq |p_{s-t}^\epsilon \ast \mu|_{B^{\gamma + \theta \Gamma}_{\ell,m}} + \int_t^s du \left[ \left\{ \mathcal{B}_{\tilde{\rho}_{t,\mu}^\epsilon}^\epsilon(v, \cdot) \rho_{t,\mu}^\epsilon(v, \cdot) \right\} \ast \nabla p_{s-u}^\epsilon \right](\cdot) \bigg|_{B^{\gamma + \theta \Gamma}_{\ell,m}}. \quad (3.3)$$

At this point, the strategy consists in handling the term

$$\left[ \left\{ \mathcal{B}_{\tilde{\rho}_{t,\mu}^\epsilon}^\epsilon(v, \cdot) \rho_{t,\mu}^\epsilon(v, \cdot) \right\} \ast \nabla p_{s-u}^\epsilon \right](\cdot) \bigg|_{B^{\gamma + \theta \Gamma}_{\ell,m}}, \quad (3.4)$$

by applying Lemma 4 with $\mathcal{C} = \mathcal{B}_{\tilde{\rho}_{t,\mu}^\epsilon}^\epsilon(v, \cdot)$ (so that $f = b^\epsilon(v, \cdot)$, $g_1 = g_2 = \tilde{\rho}_{t,\mu}^\epsilon(v, \cdot)$) and $h = \nabla p_{s-u}^\epsilon$. This gives,

$$\left| \mathcal{B}_{\tilde{\rho}_{t,\mu}^\epsilon}^\epsilon(v, \cdot) \rho_{t,\mu}^\epsilon(v, \cdot) \right| \ast \nabla p_{s-u}^\epsilon \right|_{B^{\gamma + \theta \Gamma}_{\ell,m}} \leq c_{cv} |b^\epsilon(v, \cdot)|_{B^{\gamma_f}_{1,\mu}} \left| \tilde{\rho}_{t,\mu}^\epsilon(v, \cdot) \right|_{B^{\gamma - \gamma_f}_{1,\mu}} \left| \rho_{t,\mu}^\epsilon(v, \cdot) \right|_{L^{\gamma_f}_{s-u}} \left| \nabla p_{s-u}^\epsilon \right|_{B^{\gamma + \theta \Gamma}_{\ell,m}}$$

provided

$$(\ell_f)^{-1} + (\ell_\mu)^{-1} + (\ell_g)^{-1} + (\ell_h)^{-1} = 2 + \ell^{-1}, \quad m_b \leq m, \quad m^{-1}_g \geq (1 - m^{-1}_b) \vee 0. \quad (3.5)$$

A way to get rid of the somehow quadratic dependence in $\tilde{\rho}_{t,\mu}^\epsilon$ in the above term consists in choosing $\ell_g = 1$ to exploit that we are actually dealing with probability densities: $|\tilde{\rho}_{t,\mu}^\epsilon(v, \cdot)|_{L^1} = 1$. Since we also want some compatibility between the Besov norm with which we will estimate $\tilde{\rho}_{t,\mu}^\epsilon(s, \cdot)$ in the left hand side of \[(3.3)\] and the one associated with the same quantity $\rho_{t,\mu}^\epsilon(v, \cdot)$ in the right hand side of the same equation, this also imposes $\ell_g = \ell, m_g = m$. In particular, these choices therefore yield from \[(3.3)\] that $\ell_f + \ell_h = 1$. Since $\ell_f = p$, corresponding to the initial integrability index of the singular kernel $b^\epsilon$, this yields $\ell_b = p'$ recalling $p + p' = 1$. This will contribute to the time-singularity associated with the Besov norm of the gradient of the stable heat kernel, see \[(HK)\].

The other parameters in \[(3.3)\] also naturally follow from the considered assumptions at hand. Namely, since the interaction kernel $f = b^\epsilon(v, \cdot)$ lies in the Besov space $B_{p,q}^\gamma$ uniformly in $\epsilon > 0$, this suggests to choose $\gamma_f = \beta$. Then, from the condition \[(5.5)\], we get $m_g = m$, $m^{-1} \geq (1 - m^{-1}) \vee 0$. Since $m_f = q$ (assumption on $b^\epsilon$), $m = q' = m_g$ is a natural choice. Let us now fix $m_h$ so that $m \geq m_h$. This again yields the natural choice $m_h = 1$, which gives the lowest singularity exponent for the stable heat kernel (see \[(HK)\)). When doing so, we thus obtain

$$|\tilde{\rho}_{t,\mu}^\epsilon(s, \cdot)|_{B^{\gamma + \theta \Gamma}_{\ell',\mu'}} \leq |p_{s-t}^\epsilon \ast \mu|_{B^{\gamma + \theta \Gamma}_{\ell',\mu'}} + c_{cv} \int_t^s du |b^\epsilon(v, \cdot)|_{B^{\gamma_f}_{1,\mu'}} \left| \tilde{\rho}_{t,\mu}^\epsilon(v, \cdot) \right|_{B^{\gamma - \gamma_f}_{1,\mu'}} \left| \rho_{t,\mu}^\epsilon(v, \cdot) \right|_{L^{\gamma_f}_{s-u}} \left| \nabla p_{s-u}^\epsilon \right|_{B^{\gamma + \theta \Gamma}_{\ell',\mu'}}. \quad (3.6)$$

The only parameter that remains to be fixed is the integrability index $\ell$. A natural choice is given by $\ell = p'$ (this can indeed be seen from the proof of Lemma 4 where the relations $(\ell_x)^{-1} + (\ell_y)^{-1} = 1 + \ell^{-1}$ and $(\ell_x)^{-1} + (\ell_y)^{-1} = (\ell_x)^{-1}$ naturally yields to $\ell_x = 1$, $\ell_y = \infty$, which gives in turn that $\ell = \ell_x = \ell_y = p'$). Eventually, to ensure the compatibility between the Besov norms on $\tilde{\rho}_{t,\mu}^\epsilon$ appearing in the above right and left hand sides, we use the embedding \[(E)\] which ensures that $B^{\gamma + \theta \Gamma}_{\ell',\mu'} \hookrightarrow B^{\gamma + \theta \Gamma}_{\ell,\mu}$, as $\theta \Gamma \geq 0$. We end up with the following estimate:

$$|\tilde{\rho}_{t,\mu}^\epsilon(s, \cdot)|_{B^{\gamma + \theta \Gamma}_{\ell',\mu'}} \leq |p_{s-t}^\epsilon \ast \mu|_{B^{\gamma + \theta \Gamma}_{\ell,\mu}} + c_{cv} C \int_t^s du |b^\epsilon(v, \cdot)|_{B^{\gamma_f}_{1,\mu'}} \left| \tilde{\rho}_{t,\mu}^\epsilon(v, \cdot) \right|_{B^{\gamma - \gamma_f}_{1,\mu'}} \left| \rho_{t,\mu}^\epsilon(v, \cdot) \right|_{L^{\gamma_f}_{s-u}} \left| \nabla p_{s-u}^\epsilon \right|_{B^{\gamma + \theta \Gamma}_{\ell,\mu}},$$

i.e. we applied Lemma 4 with $\ell = p'$, $m = q'$, $\gamma = -\beta + \theta \Gamma$, $\ell_f = p$, $m_f = q$, $\gamma_f = \beta$, $\ell_g = 1$, $\ell_h = p'$, $m_g = q'$, $\ell_h = p'$, $m_h = 1$, on the second term in the right hand side of \[(3.3)\] and used eventually \[(E)\].

Thus, using \[(HK)\] and applying the $L^1 : L^r - L^{r'}$ – Hölder inequality in time, we obtain:

$$|\tilde{\rho}_{t,\mu}^\epsilon(s, \cdot)|_{B^{\gamma + \theta \Gamma}_{\ell',\mu'}} \leq |p_{s-t}^\epsilon \ast \mu|_{B^{\gamma + \theta \Gamma}_{\ell,\mu}} + C|b^\epsilon|_{L^r(B^{\gamma}_{p'})} \left( \int_t^s \frac{dv}{(s-v)^{\frac{\alpha}{\alpha + p} + \frac{1}{p} + \frac{1}{\alpha}}} \right) \left| \tilde{\rho}_{t,\mu}^\epsilon(v, \cdot) \right|_{B^{\gamma' + \theta \Gamma}_{\ell',\mu'}}. \quad (3.7)$$

which actually gives an integrable singularity in time as soon as

$$\left( \frac{-\beta + \theta \Gamma}{\alpha} + \frac{d}{\alpha p} + \frac{1}{\alpha} \right) p' < 1 \iff \beta - \theta \Gamma > \frac{d}{p} + 1 + \frac{\alpha}{r} - \alpha \iff (1-\theta)\Gamma > 0.$$
Note that this condition is indeed fulfilled from (C0) and (G) for any \( \vartheta \in [0,1) \). Write now from the Young inequality (Y) and (HK):

\[
|p^{a}_{s-t} * \mu|_{B^{-\beta+\vartheta}_{p',q'}} \leq C \frac{C}{(s-t)^{\frac{\beta}{\alpha} + \frac{\vartheta}{\alpha}}},
\]

using as well Lemma 3 which precisely gives that any \( \mu \in P(\mathbb{R}^d) \in B^{1}_{1,\infty} \), for the last inequality. The above controls precisely allow to specify the range for the parameter \( \tilde{r} \) for which we will be able to estimate the \( L^{r}(B^{\beta}_{p',q'}) \) norm of the density. Namely, one gets:

\[
|p^{a}_{s-t} * \mu|_{B^{-\beta+\vartheta}_{p',q'}} \leq C \frac{C}{(s-t)^{\frac{\beta}{\alpha} + \frac{\vartheta}{\alpha}}},
\]

which gives an integrable singularity in time provided the integrability condition (3.1) holds for \( \tilde{r} \).

Taking now both sides of (3.7) to the exponent \( \tilde{r} \), we then get from usual convexity inequalities and integrating then in \( s \in [t,T] \) that,

\[
\int_{t}^{T} ds|\rho^{\infty}_{t,\mu}(s,.)|_{B^{-\beta+\vartheta}_{p',q'}} \leq 2^{\tilde{r}-1} \int_{t}^{T} ds|p^{a}_{s-t} * \mu|_{B^{-\beta+\vartheta}_{p',q'}} + C|b^{r}|_{L^{r}(B^{\beta}_{p',q'})} \left( \int_{t}^{T} \frac{ds}{(s-v)(\frac{\alpha r}{\alpha + p} + \frac{1}{\alpha})} \right)^{\frac{1}{r}}
\]

Since we are considering compact time intervals, we can assume w.l.o.g. that \( \tilde{r} > r' \) so that the H"{o}lder inequality \( L^{1} : L^{r}/r' - L^{(1-r')/r'}^{-1} \) applies and combined with a splitting of the \( (r')^{th} \) power of the time singularity as \( r'(r'/T) + r'(1 - r'/T) \), it yields to

\[
\int_{t}^{T} ds|\rho^{\infty}_{t,\mu}(s,.)|_{B^{-\beta+\vartheta}_{p',q'}} \leq 2^{\tilde{r}-1} \int_{t}^{T} ds|p^{a}_{s-t} * \mu|_{B^{-\beta+\vartheta}_{p',q'}} + C|b^{r}|_{L^{r}(B^{\beta}_{p',q'})} \left( \int_{t}^{T} \frac{ds}{(s-v)(\frac{\alpha r}{\alpha + p} + \frac{1}{\alpha})} \right)^{\frac{1}{r}}
\]

Therefore, setting

\[
\delta := 1 - \left( \frac{-\beta + \vartheta T}{\alpha} + \frac{d}{pa} + \frac{1}{\alpha} \right) r' > 0,
\]

from conditions (C0) and (G), using then the Fubini theorem, one gets:

\[
\int_{t}^{T} ds|\rho^{\infty}_{t,\mu}(s,.)|_{B^{-\beta+\vartheta}_{p',q'}} \leq 2^{\tilde{r}-1} \left( \int_{t}^{T} ds|p^{a}_{s-t} * \mu|_{B^{-\beta+\vartheta}_{p',q'}} + C(T-t)^{\delta(r'-1)} |b^{r}|_{L^{r}(B^{\beta}_{p',q'})} \int_{t}^{T} \frac{ds}{(s-v)(\frac{\alpha r}{\alpha + p} + \frac{1}{\alpha})} \right)^{\frac{1}{r}}
\]

Recalling now (3.10) and (3.11), as well as the uniform control of \( b^{r} \) given in Proposition 3, we get that there exists \( \theta > 0 \) s.t. for \( T \) small enough:

\[
\left( \int_{t}^{T} ds|\rho^{\infty}_{t,\mu}(s,.)|_{B^{-\beta+\vartheta}_{p',q'}} \right)^{\frac{1}{r}} \leq C(T-t)^{\theta}.
\]

Let us turn to the proof of (3.22). Restart from (3.7) taking both sides to the exponent \( r' \). Apply a convexity inequality to distribute the exponent on all the terms of the r.h.s., multiply by \( (S-s)^{-\frac{1}{r'}} \) for
$t < S \leq T$ and integrate the resulting expression on $(t, S]$, we obtain:

$$
\int_t^S \frac{ds}{(S-s)^{\frac{\beta}{p} + \frac{\beta}{q} + 1}} \rho^c_{t, \mu}(s, \cdot) \frac{d^\beta v}{(s-v)^{\frac{\beta}{p} + \frac{\beta}{q} + 1}} \rho^c_{t, \mu}(v, \cdot) \leq C_{t, \mu} \int_t^S \frac{ds}{(S-s)^{\frac{\beta}{p} + \frac{\beta}{q} + 1}} \rho^c_{t, \mu}(s, \cdot) \frac{d^\beta v}{(s-v)^{\frac{\beta}{p} + \frac{\beta}{q} + 1}} \rho^c_{t, \mu}(v, \cdot)
$$

using the Fubini theorem and (3.5) to derive the last inequality. Since

$$
\frac{-\beta + \vartheta \Gamma}{\alpha} + \frac{d}{\alpha} + \frac{1}{\alpha} > \tilde{r} \iff \beta - \vartheta \Gamma > \frac{d}{\alpha} + \frac{1}{\alpha} \iff (1 - \vartheta) \Gamma > \alpha \left( \frac{1}{\tilde{r}} - \frac{1}{r} \right),
$$

it is clear that for a fixed $\vartheta \in [0,1)$, $\tilde{r}$ can be taken large enough in order to have an integrable singularity in the previous expression. Namely,

$$
\tilde{r} \in \left( \frac{(1 - \vartheta) \Gamma}{\alpha} + \frac{1}{\alpha}, r \right) \implies \tilde{\delta} := 1 - \left( \frac{-\beta + \vartheta \Gamma}{\alpha} + \frac{d}{\alpha} + \frac{1}{\alpha} \right) \tilde{r} > 0. \tag{3.13}
$$

From (3.13) we get that:

$$
\int_t^S \frac{ds}{(S-s)^{\frac{\beta}{p} + \frac{\beta}{q} + 1}} \rho^c_{t, \mu}(s, \cdot) \frac{d^\beta v}{(s-v)^{\frac{\beta}{p} + \frac{\beta}{q} + 1}} \rho^c_{t, \mu}(v, \cdot) \leq C(S-t)^\delta + C|\tilde{r}| \frac{d^\beta v}{(s-v)^{\frac{\beta}{p} + \frac{\beta}{q} + 1}} \rho^c_{t, \mu}(v, \cdot) \leq 2C (S-t)^\delta,
$$

as soon as $S - t$ is small enough to have $C|\tilde{r}| \frac{d^\beta v}{(s-v)^{\frac{\beta}{p} + \frac{\beta}{q} + 1}} \rho^c_{t, \mu}(v, \cdot) \leq 1/2$ for the last but one inequality. Identifying the norm $| \cdot |_{L^\delta(B_{\rho^c_{\vartheta} - \delta}^c)(t, S]}$ on the left-hand side, this gives (3.2) and concludes the proof of the Lemma.

**Lemma 8 (Stability Lemma).** For any initial condition $(t, \mu) \in [0,T] \times \mathcal{P}(\mathbb{R}^d)$, for any decreasing sequence $(\varepsilon_k)_{k \geq 1}$ s.t. $\varepsilon_k \to 0$, $(\rho_{\varepsilon_k}^c)_{k \geq 1}$ is a Cauchy sequence in $L^\delta(B_{\rho^c_{\vartheta} - \delta}^c) \cap L^\infty((t,T), \mathbb{L})$, for any $\vartheta \in (0,1)$ with $\tilde{\vartheta}$ as in (3.11) and $\Gamma$ as in [C]. In particular, there exists $\rho_{t, \mu}$ in $L^\delta(B_{\rho^c_{\vartheta} - \delta}^c) \cap L^\infty((t,T), \mathbb{L})$ such that

$$
|\rho_{t, \mu}^c - \rho_{t, \mu}|_{L^\delta(B_{\rho^c_{\vartheta} - \delta}^c)} + \sup_{s \in (t,T)} |(\rho_{t, \mu}^c - \rho_{t, \mu})(s, \cdot)|_{L^1} \to 0. \tag{3.14}
$$

**Proof.** Fix $k, j \in \mathbb{N}$ meant to be large. Assume w.l.o.g. that $k \geq j$. From (1.10), for any $m \in \{ k, j \}$, $\rho_{\varepsilon_k}^c$ solves:

$$
\rho_{\varepsilon_k}^c(s, y) = \rho_{s-t}^c \ast \mu(y) - \int_t^s \frac{d^\beta v}{(s-v)^{\frac{\beta}{p} + \frac{\beta}{q} + 1}} \rho_{\varepsilon_k}^c(v, \cdot) \rho_{\varepsilon_k}^c(v, \cdot) \ast \nabla \rho_{s-v}^c(y),
$$

where we recall that, from Lemma 7, $\rho_{\varepsilon_k}^c \in L^\delta(B_{\rho^c_{\vartheta} - \delta}^c)$ with $\tilde{\vartheta}$ as in (3.11). We have

$$
\rho_{\varepsilon_k}^c(s, y) - \rho_{\varepsilon_j}^c(s, y) = - \int_t^s \frac{d^\beta v}{(s-v)^{\frac{\beta}{p} + \frac{\beta}{q} + 1}} \rho_{\varepsilon_k}^c(v, \cdot) \rho_{\varepsilon_k}^c(v, \cdot) - \rho_{\varepsilon_j}^c(v, \cdot) \rho_{\varepsilon_j}^c(v, \cdot) \ast \nabla \rho_{s-v}^c(y).
$$

To show that $|\rho_{t, \mu}^c - \rho_{t, \mu}|_{L^\delta(B_{\rho^c_{\vartheta} - \delta}^c)}$ is small, we will proceed somehow similarly to the proof of Lemma 7. The convolution inequalities used therein (see e.g. Lemma 4 yielding to (3.7)) then naturally lead to estimate the $L^1$ norm of the difference $(\rho_{t, \mu}^c - \rho_{t, \mu})(v, \cdot)$ for $v \in [t, s], s \in [t, T]$. We will use the same
Similarly to the proof of Lemma 7, applying Lemma 4 successively (and respectively) to the maps $b^ε_{\rho_{t,\mu}}(s, \cdot)$ for the latter) of the difference. Write for any $\gamma \geq 0, \ell, m \geq 1$:

\[
|\rho_{t,\mu}^\gamma(s, \cdot) - \rho_{t,\mu}^\gamma(s, \cdot)|_{B^\gamma_{m, \cdot}} \leq \int_t^s dv \left\{ |B^\gamma_{\rho_{t,\mu}}(v, \cdot)\rho_{t,\mu}^\gamma(v, \cdot) - B^\gamma_{\rho_{t,\mu}}(v, \cdot)\rho_{t,\mu}^\gamma(v, \cdot)| \cdot \nu_{s-v}^{\alpha} \right\}_{B^\gamma_{m, \cdot}}
\]

\[
+ \int_t^s dv \left\{ |B^\gamma_{\rho_{t,\mu}}(v, \cdot)\rho_{t,\mu}^\gamma(v, \cdot) - B^\gamma_{\rho_{t,\mu}}(v, \cdot)\rho_{t,\mu}^\gamma(v, \cdot)| \cdot \nu_{s-v}^{\alpha} \right\}_{B^\gamma_{m, \cdot}}
\]

\[
+ \int_t^s dv \left\{ |B^\gamma_{\rho_{t,\mu}}(v, \cdot)\rho_{t,\mu}^\gamma(v, \cdot) - B^\gamma_{\rho_{t,\mu}}(v, \cdot)\rho_{t,\mu}^\gamma(v, \cdot)| \cdot \nu_{s-v}^{\alpha} \right\}_{B^\gamma_{m, \cdot}}.
\]

\[
=: \int_t^s dv \left[ \Delta^1_{\gamma, \ell, m}(t, v) + \Delta^2_{\gamma, \ell, m}(t, v) + \Delta^3_{\gamma, \ell, m}(t, v) \right]. \quad (3.15)
\]

Similarly to the proof of Lemma 7, applying Lemma 4 successively (and respectively) to the maps $f = b^\gamma_{\rho_{t,\mu}}(v, \cdot)$ (resp. $f = (b^\gamma_k(v, \cdot), f = (b^\gamma_k(v, \cdot), g_1 = \rho_{t,\mu}^\gamma(v, \cdot)$ (resp. $g_1 = \rho_{t,\mu}^\gamma(v, \cdot)$ respectively $g_2 = \rho_{t,\mu}^\gamma(v, \cdot)$) and $g_2 = \rho_{t,\mu}^\gamma(v, \cdot)$) with $\gamma = -\beta + \delta \Gamma, \ell = p, \ell = p', m = q'; \gamma_f = \beta$ (and $\gamma_f = \beta - \delta \Gamma$ for $\Delta^3_{\gamma, \ell, m}$), $\gamma = 1, \ell = q$ and $m = 1$, $\ell = q'$, $m = 1, \ell = 1, \ell = \ell_h = \ell$. From also (3.7), we derive that:

\[
\Delta^1_{-\beta + \delta \Gamma, p, q'}(t, v) \leq C |b^\gamma_{\rho_{t,\mu}}(v, \cdot)|_{B^\gamma_{p', q'}} |(\rho_{t,\mu}^\gamma(v, \cdot) - \rho_{t,\mu}^\gamma(v, \cdot)|_{L^1} |\nu_{s-v}^{\alpha} \right\}_{B_{p', q'}^{\gamma, \delta \Gamma}}
\]

\[
\Delta^2_{-\beta + \delta \Gamma, p, q'}(t, v) \leq C |b^\gamma_{\rho_{t,\mu}}(v, \cdot)|_{B^\gamma_{p', q'}} |(\rho_{t,\mu}^\gamma(v, \cdot) - \rho_{t,\mu}^\gamma(v, \cdot)|_{L^1} |\nu_{s-v}^{\alpha} \right\}_{B_{p', q'}^{\gamma, \delta \Gamma}}
\]

\[
\Delta^3_{-\beta + \delta \Gamma, p, q'}(t, v) \leq C |(b^\gamma_k(v, \cdot) - b^\gamma_k(v, \cdot)|_{B^\gamma_{p', q'}} |\rho_{t,\mu}^\gamma(v, \cdot) - \rho_{t,\mu}^\gamma(v, \cdot)|_{L^1} |\nu_{s-v}^{\alpha} \right\}_{B_{p', q'}^{\gamma, \delta \Gamma}}.
\]

Thus, (HK) together with (E) (which notably gives: $B_{p', q'}^{\gamma, \delta \Gamma} \hookrightarrow B_{p', q'}^{\gamma, \delta \Gamma}$) and (3.15) for the above choice of the parameters $\gamma, \ell, m$, give:

\[
|\rho_{t,\mu}^\gamma(s, \cdot) - \rho_{t,\mu}^\gamma(s, \cdot)|_{B_{p', q'}^{\gamma, \delta \Gamma}} \leq C \int_t^s dv \left\{ |b^\gamma_{\rho_{t,\mu}}(v, \cdot)|_{B^\gamma_{p', q'}} |(\rho_{t,\mu}^\gamma(v, \cdot) - \rho_{t,\mu}^\gamma(v, \cdot)|_{L^1} \right\}_{B_{p', q'}^{\gamma, \delta \Gamma}}.
\]

To estimate the $L^1$ norm of the above difference, come back to (3.15), take now $\gamma = 0, \ell = m = 1$ and apply Lemma 4 with the following choice of parameters: $\gamma_f = \beta, \ell_f = p$ and $m_f = q; \ell_f = p', m_f = q', \ell_f = 1$ and $m_f = 1$. Use then the embedding (E) and (HK) to obtain from the $L^1: L^1 \hookrightarrow L^1 : L^1 : L^1 - L^1$-Hölder inequalities that, for all $s \in (t, T)$,
\[ |\rho_{t,\mu}^{e}(s,\cdot) - \rho_{t,\mu}^{\tilde{e}}(s,\cdot)|_{L^1} \leq C \sup_{v \in \{t, S\}} \left\{ \left| \rho_{t,\mu}^{e}(v,\cdot) - \rho_{t,\mu}^{\tilde{e}}(v,\cdot) \right|_{L^1} \right\} \]

with \( r = r_{r} < +\infty \) and any finite \( r_{r} \) large enough if \( r = +\infty \), i.e. the conjugate exponent \( r' \) belongs to the interval indicated after (3.2). We insist that this additional step is needed when \( r = +\infty \) to use Proposition 2 which gives the convergence of the mollified interaction kernel.

Taking the supremum in \( s \) on \( (t, S] \) for some \( S \leq T \) on both sides and recalling the notation (2.6), we obtain for \( v' \in \{v', \tilde{v}'\}, \)

\[ \sup_{s \in \{t, S\}} \left\{ \left| \rho_{t,\mu}^{e}(s,\cdot) - \rho_{t,\mu}^{\tilde{e}}(s,\cdot) \right|_{L^1} \right\} \leq C \sup_{s \in \{t, S\}} \left| \rho_{t,\mu}^{e}(s,\cdot) - \rho_{t,\mu}^{\tilde{e}}(s,\cdot) \right|_{L^1} \]

Thus, from (3.2) for \( T \) such that \( |b|_{L^p(B_{\rho_{1}}^{\alpha})} (T - t)^{1/p'} \leq c \), \( \delta = \bar{\delta}(r') \) and Proposition 2, we obtain

\[ \sup_{s \in \{t, S\}} \left\{ \left| \rho_{t,\mu}^{e}(s,\cdot) - \rho_{t,\mu}^{\tilde{e}}(s,\cdot) \right|_{L^1} \right\} \leq C \left( |b|_{L^p(B_{\rho_{1}}^{\alpha})} + (s - t)^{1/p'} \right) \]

The above control provides the estimate for the running norm \( s \mapsto \sup_{v \in \{t, S\}} \left\{ \left| \rho_{t,\mu}^{e}(v,\cdot) - \rho_{t,\mu}^{\tilde{e}}(v,\cdot) \right|_{L^1} \right\} \), which plugged into (3.10) yields

\[ \left| \rho_{t,\mu}^{e}(s,\cdot) - \rho_{t,\mu}^{\tilde{e}}(s,\cdot) \right|_{B_{\rho_{1}}^{\alpha-\delta}} \leq C \left\{ \left| b \right|_{L^p(B_{\rho_{1}}^{\alpha})} \sup_{s \in \{t, S\}} \left( \left| \rho_{t,\mu}^{e}(s,\cdot) - \rho_{t,\mu}^{\tilde{e}}(s,\cdot) \right|_{L^1} \right) \right\} \]

At this stage, we can proceed similarly as in the proof of Lemma 4 leaving the component factored by \( \left| b \right|_{L^p(B_{\rho_{1}}^{\alpha-\delta})} \) as a source term. Use first the \( L^1 : L^{r} \rightarrow L^{r} \)-Hölder inequality for the first two terms in the above integrals and the \( L^1 : L^{r} \rightarrow L^{r} \) for the last integral term. Multiply then both sides by
\[(S - s)^{-1/\alpha} \text{ for some } s < S \leq T. \text{ Take next the } (r')^{th} \text{ power, use consequently a convexity inequality in the resulting expression and finally integrate the whole on } (t, S]. \text{ We eventually obtain}
\[
\int_t^S \frac{ds}{(S - s)^{\alpha}} |\rho_{t,\mu}^{\ell, k}(s, \cdot) - \rho_{t,\mu}^{\ell, j}(s, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \leq C \left\{ \left| b^{\ell,k} \right|_{L_p(B_{p,q}^{\beta + \sigma})} \sup_{v \in (t, S]} \left( |\rho_{t,\mu}^{\ell, k}(v, \cdot) - \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} + (S - t) \frac{d}{dp} \right) \right\} \times \int_t^S \frac{ds}{(S - s)^{\alpha}} \int_t^S \frac{dv}{(v - t)^{\alpha}} \left( \left| \rho_{t,\mu}^{\ell, k}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \left| \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \right. \\
+ C \left\{ \left| b^{\ell,k} - b^{\ell,j} \right|_{L_p(B_{p,q}^{\beta + \sigma})} \left( S - t \right)^{\frac{d}{dp}} \int_t^S \frac{dv}{(v - t)^{\alpha}} \left( \left| \rho_{t,\mu}^{\ell, k}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \left| \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \right. \\
+ \left( \left| b^{\ell,k} - b^{\ell,j} \right|_{L_p(B_{p,q}^{\beta + \sigma})} \left( S - t \right)^{\frac{d}{dp}} \int_t^S \frac{dv}{(v - t)^{\alpha}} \left( \left| \rho_{t,\mu}^{\ell, k}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \left| \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \right. \\
\leq C \left\{ \left| b^{\ell,k} \right|_{L_p(B_{p,q}^{\beta + \sigma})} \sup_{v \in (t, S]} \left( |\rho_{t,\mu}^{\ell, k}(v, \cdot) - \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} + (S - t) \frac{d}{dp} \right) \right\} \times \int_t^S \frac{dv}{(v - t)^{\alpha}} \left( \left| \rho_{t,\mu}^{\ell, k}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \left| \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right. \\
+ C \left\{ \left| b^{\ell,k} - b^{\ell,j} \right|_{L_p(B_{p,q}^{\beta + \sigma})} \left( S - t \right)^{\frac{d}{dp}} \int_t^S \frac{dv}{(v - t)^{\alpha}} \left( \left| \rho_{t,\mu}^{\ell, k}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \left| \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \right. \\
+ \left( \left| b^{\ell,k} - b^{\ell,j} \right|_{L_p(B_{p,q}^{\beta + \sigma})} \left( S - t \right)^{\frac{d}{dp}} \int_t^S \frac{dv}{(v - t)^{\alpha}} \left( \left| \rho_{t,\mu}^{\ell, k}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \left| \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \right. \\

\text{From the Fubini theorem and using again the } L^1 : L^\infty - L^{r'} \text{ inequality for the last contribution if } r' = 1 < r' \text{ ( } \Leftrightarrow r = \infty, \ r' < +\infty \text{), we now derive:}
\[
\int_t^S \frac{ds}{(S - s)^{\alpha}} |\rho_{t,\mu}^{\ell, k}(s, \cdot) - \rho_{t,\mu}^{\ell, j}(s, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \leq C \left\{ \left| b^{\ell,k} \right|_{L_p(B_{p,q}^{\beta + \sigma})} \sup_{v \in (t, S]} \left( |\rho_{t,\mu}^{\ell, k}(v, \cdot) - \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} + (S - t) \frac{d}{dp} \right) \right\} \times \int_t^S \frac{dv}{(v - t)^{\alpha}} \left( \left| \rho_{t,\mu}^{\ell, k}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \left| \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right. \\
+ C \left\{ \left| b^{\ell,k} - b^{\ell,j} \right|_{L_p(B_{p,q}^{\beta + \sigma})} \left( S - t \right)^{\frac{d}{dp}} \int_t^S \frac{dv}{(v - t)^{\alpha}} \left( \left| \rho_{t,\mu}^{\ell, k}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \left| \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \right. \\
+ \left( \left| b^{\ell,k} - b^{\ell,j} \right|_{L_p(B_{p,q}^{\beta + \sigma})} \left( S - t \right)^{\frac{d}{dp}} \int_t^S \frac{dv}{(v - t)^{\alpha}} \left( \left| \rho_{t,\mu}^{\ell, k}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \left| \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \right. \\
\leq C \left\{ \left| b^{\ell,k} \right|_{L_p(B_{p,q}^{\beta + \sigma})} \sup_{v \in (t, T]} \left( |\rho_{t,\mu}^{\ell, k}(v, \cdot) - \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} + (S - t) \frac{d}{dp} \right) \right\} \times \int_t^S \frac{dv}{(v - t)^{\alpha}} \left( \left| \rho_{t,\mu}^{\ell, k}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \left| \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right. \\
+ C \left\{ \left| b^{\ell,k} - b^{\ell,j} \right|_{L_p(B_{p,q}^{\beta + \sigma})} \left( S - t \right)^{\frac{d}{dp}} \int_t^S \frac{dv}{(v - t)^{\alpha}} \left( \left| \rho_{t,\mu}^{\ell, k}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \left| \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \right. \\
+ \left( \left| b^{\ell,k} - b^{\ell,j} \right|_{L_p(B_{p,q}^{\beta + \sigma})} \left( S - t \right)^{\frac{d}{dp}} \int_t^S \frac{dv}{(v - t)^{\alpha}} \left( \left| \rho_{t,\mu}^{\ell, k}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \left| \rho_{t,\mu}^{\ell, j}(v, \cdot)||^r_{L_p(B_{p,q}^{\beta + \sigma})} \right| \right) \right. \\
\text{where, for the last inequality, we use the uniform controls on } b^{\ell} \text{ and } \rho_{t,\mu}^{\ell, k} \text{ given by Proposition 3 and 5.2 in Lemma 4 and the fact that, from (5.11) and (5.13):}
\[-\delta = r' \left( -\frac{\beta + \vartheta t}{\alpha} + \frac{d}{ap} \right) - 1 \leq 0, \quad -\bar{\delta} = \bar{r}' \left( -\frac{\beta + \vartheta \Gamma}{\alpha} + \frac{d}{ap} \right) - 1 \leq 0 \]
(the contribution $1/\tilde{r}$ in the last power only arises when $r = \infty$). Taking now the supremum over $S \in (t, T]$, we recover on the left-hand side above the quantity \( \sup_{v \in (t, T]} \| (\rho^E_{t,\mu} - \rho^{E,j}_{t,\mu}) \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} \) and for $T > t \geq 0$ small enough, we deduce that there exists $C \geq 1$ s.t.

\[
\sup_{v \in (t, T]} \| (\rho^E_{t,\mu} - \rho^{E,j}_{t,\mu}) \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} \leq C \| (b^{E,k} - b^{E,j}) \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])}, \tag{3.19}
\]

As $|\rho^E_{t,\mu} - \rho^{E,j}_{t,\mu}|_{L^\infty_{\tilde{r}'}((t,T],[B^{-\beta_0+\gamma}\bar{r}])} \leq \sup_{v \in (t, T]} \| (\rho^E_{t,\mu} - \rho^{E,j}_{t,\mu}) \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])}$ and $L^\infty_{\tilde{r}'}((t,T],[B^{-\beta_0+\gamma}\bar{r}])$ is complete we have, from Proposition 2 that the convergence of $(\rho^E_{t,\mu})_{k \geq 1}$ holds in $L^\infty_{\tilde{r}'}((t,T],[B^{-\beta_0+\gamma}\bar{r}])$. The strong convergence in $L^\infty_{L^1}$ follows from (3.17), again Proposition 2 and (3.19). The proof of (3.14) is thus complete for $\tilde{r} = r'$. Let us now discuss how we can improve the integrability exponent $\tilde{r}$ for the convergence to prove (3.14) in full generality. Restating from (3.18), write first for $\tilde{r}$ satisfying (3.1)

\[
\int_T^T |\rho^E_{t,\mu}(s, \cdot) - \rho^{E,j}_{t,\mu}(s, \cdot)|_{B^{-\beta_0+\gamma}\bar{r}} ds \leq C \left\{ \int_T^T \| b^{E,k}_{t,\mu} - b^{E,j}_{t,\mu} \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} + (T-t)^{\frac{\beta_0}{\tilde{r}'}} \right\}
\]

\[
\times \sup_{v \in (t, T]} \| (\rho^E_{t,\mu} - \rho^{E,j}_{t,\mu}) \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} \frac{dv}{(s-v)^{\tilde{r}'\bar{r}}} \leq C \left\{ \int_T^T \| b^{E,k}_{t,\mu} - b^{E,j}_{t,\mu} \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} + (T-t)^{\frac{\beta_0}{\tilde{r}'}} \right\}
\]

\[
\times \sup_{v \in (t, T]} \| (\rho^E_{t,\mu} - \rho^{E,j}_{t,\mu}) \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} \frac{dv}{(s-v)^{\tilde{r}'\bar{r}}} \leq C \left\{ \int_T^T \| b^{E,k}_{t,\mu} - b^{E,j}_{t,\mu} \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} + (T-t)^{\frac{\beta_0}{\tilde{r}'}} \right\}
\]

\[
\times \sup_{v \in (t, T]} \| (\rho^E_{t,\mu} - \rho^{E,j}_{t,\mu}) \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} \frac{dv}{(s-v)^{\tilde{r}'\bar{r}}}.
\]

Now conclude as in the proof of Lemma 7 through again an additional Hölder inequality and the Fubini theorem (see the procedure between (3.10) and (3.12)). Namely,

\[
\int_T^T |\rho^E_{t,\mu}(s, \cdot) - \rho^{E,j}_{t,\mu}(s, \cdot)|_{B^{-\beta_0+\gamma}\bar{r}} ds \leq C \left\{ \int_T^T \| b^{E,k}_{t,\mu} - b^{E,j}_{t,\mu} \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} + (T-t)^{\frac{\beta_0}{\tilde{r}'}} \right\}
\]

\[
\times \sup_{v \in (t, T]} \| (\rho^E_{t,\mu} - \rho^{E,j}_{t,\mu}) \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} \frac{dv}{(s-v)^{\tilde{r}'\bar{r}}} \leq C \left\{ \int_T^T \| b^{E,k}_{t,\mu} - b^{E,j}_{t,\mu} \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} + (T-t)^{\frac{\beta_0}{\tilde{r}'}} \right\}
\]

\[
\times \sup_{v \in (t, T]} \| (\rho^E_{t,\mu} - \rho^{E,j}_{t,\mu}) \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} \frac{dv}{(s-v)^{\tilde{r}'\bar{r}}} \leq C \left\{ \int_T^T \| b^{E,k}_{t,\mu} - b^{E,j}_{t,\mu} \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} + (T-t)^{\frac{\beta_0}{\tilde{r}'}} \right\}
\]

\[
\times \sup_{v \in (t, T]} \| (\rho^E_{t,\mu} - \rho^{E,j}_{t,\mu}) \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} \frac{dv}{(s-v)^{\tilde{r}'\bar{r}}} \leq C \left\{ \int_T^T \| b^{E,k}_{t,\mu} - b^{E,j}_{t,\mu} \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} + (T-t)^{\frac{\beta_0}{\tilde{r}'}} \right\}
\]

\[
\times \sup_{v \in (t, T]} \| (\rho^E_{t,\mu} - \rho^{E,j}_{t,\mu}) \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} \frac{dv}{(s-v)^{\tilde{r}'\bar{r}}} \begin{cases}
\begin{array}{ll}
\leq C \int_T^T \| b^{E,k}_{t,\mu} - b^{E,j}_{t,\mu} \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} + (T-t)^{\frac{\beta_0}{\tilde{r}'}} \times \sup_{v \in (t, T]} \| (\rho^E_{t,\mu} - \rho^{E,j}_{t,\mu}) \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])} \frac{dv}{(s-v)^{\tilde{r}'\bar{r}}} + 1 & \text{if } \tilde{r}' < r' \\
\leq C(T-t)^{\frac{\beta_0}{\tilde{r}'}} \| b^{E,k}_{t,\mu} - b^{E,j}_{t,\mu} \|_{L^\infty_{\tilde{r}'}((t,v],[B^{-\beta_0+\gamma}\bar{r}])}, & \text{if } \tilde{r}' = r' \end{array}
\end{cases}
\end{array}
\]
Lemma 9. Let \((t, \mu) \in [0, T] \times \mathcal{P}(\mathbb{R}^d)\) and let \((\varepsilon_k)_{k \geq 1}\) be a decreasing sequence going to 0 and \(\rho_{t, \mu}\) in \(L^1(B_{p,q}^{-\beta+\theta^*}(\mathbb{R}^d))\), with \(\bar{r}\) as in (3.1), \(0 \in [0, 1]\) and s.t. for all \(s \in [t, T], \rho_{t, \mu}(s, \cdot) \in \mathcal{P}(\mathbb{R}^d)\), be the limit point of \((\rho_{t, \mu}^{\varepsilon_k})_{k \geq 1}\) with \(\rho_{t, \mu}^{\varepsilon_k}\), solving (1.18). Then \(\rho_{t, \mu}\) satisfies the non-linear Fokker-Planck equation (1.19) (in a distributional sense) and admits the Duhamel type representation (1.18).

Proof. We assume here w.l.o.g. and for simplicity that \(r < +\infty\). The case \(r = +\infty\) could be handled reproducing the arguments below combined with the corresponding ones in the proof of the previous lemma. Write from (1.17):

\[
0 = -\int_0^T \varphi(t, y) \mu(dy) - \int_t^T ds \int \mathbb{R}^d dy \left( \mathcal{B}_{t, \mu}^{\varepsilon_k}(s, y) \rho_{t, \mu}^{\varepsilon_k}(s, y) \right) \cdot \nabla \varphi(s, y) + \int_t^T ds \int \mathbb{R}^d dy \rho_{t, \mu}(s, y) (-\partial_s + (L^\alpha)^*) \varphi(s, y) + \Delta_{\rho_{t, \mu}} \rho_{t, \mu}^{\varepsilon_k} (\varphi),
\]

where:

\[
\Delta_{\rho_{t, \mu}} \rho_{t, \mu}^{\varepsilon_k} (\varphi) := \int_0^T ds \int \mathbb{R}^d dy \left( \rho_{t, \mu}^{\varepsilon_k}(s, y) - \rho_{t, \mu}(s, y) \right) (-\partial_s + (L^\alpha)^*) \varphi(s, y) - \int_t^T ds \int \mathbb{R}^d dy \left( \mathcal{B}_{t, \mu}^{\varepsilon_k}(s, y) \rho_{t, \mu}^{\varepsilon_k}(s, y) - \mathcal{B}_{t, \mu}(s, y) \rho_{t, \mu}(s, y) \right) \cdot \nabla \varphi(s, y) = \Delta^1_{\rho_{t, \mu}} \rho_{t, \mu}^{\varepsilon_k} (\varphi) + \Delta^2_{\rho_{t, \mu}} \rho_{t, \mu}^{\varepsilon_k} (\varphi).
\]

Since \(\varphi \in C_0^\infty((-T, T) \times \mathbb{R}^d)\) it is clear that \((-\partial_s - (L^\alpha)^*) \varphi \in L^r(B_{p,q}^2)\) so that we readily get from (3.14) that \(\|\Delta^1_{\rho_{t, \mu}} \rho_{t, \mu}^{\varepsilon_k} (\varphi)\| \rightarrow 0\).

For the second term \(\Delta^2_{\rho_{t, \mu}} \rho_{t, \mu}^{\varepsilon_k} (\varphi)\), write:

\[
\|\Delta^2_{\rho_{t, \mu}} \rho_{t, \mu}^{\varepsilon_k} (\varphi)\| \leq \int_t^T ds \int \mathbb{R}^d dy \left| \mathcal{B}_{t, \mu}^{\varepsilon_k}(s, y) \rho_{t, \mu}^{\varepsilon_k}(s, y) - \mathcal{B}_{t, \mu}(s, y) \rho_{t, \mu}(s, y) \right| \|\nabla \varphi(s, \cdot)\|_{L^\infty} \leq \|\nabla \varphi\|_{L^\infty(L^\infty)} \int_t^T ds \left\{ \int \mathbb{R}^d dy \mathcal{B}_{t, \mu}^{\varepsilon_k}(s, \cdot) - \mathcal{B}_{t, \mu}(s, \cdot) \right\}_{L^\infty} \rho_{t, \mu}^{\varepsilon_k}(s, y) + \int \mathbb{R}^d dy \left( \mathcal{B}_{t, \mu}(s, \cdot) - \mathcal{B}_{t, \mu}(s, \cdot) \right)_{L^\infty} \rho_{t, \mu}^{\varepsilon_k}(s, y).
\]

Recalling that \(\rho_{t, \mu}^{\varepsilon_k}(s, \cdot)\) is a probability density and using as well the duality control (12) between Besov spaces and the Hölder inequality in time, we derive that for any \(\theta \in (0, 1)\):

\[
\|\Delta^2_{\rho_{t, \mu}} \rho_{t, \mu}^{\varepsilon_k} (\varphi)\| \leq C \left\{ \| b - b^{\varepsilon_k}\|_{L^r(B_{p,q}^\theta; B_{p,q}^{\mu+\theta^*})} \right\} \|\rho_{t, \mu}\|_{L^r(B_{p,q}^{\theta^*+\theta^*^*})} \rho_{t, \mu}^{\varepsilon_k} + \| b \|_{L^r(B_{p,q}^{\theta^*})} \|\rho_{t, \mu}\|_{L^r(B_{p,q}^{\theta^*})} \rho_{t, \mu}^{\varepsilon_k} + \| b \|_{L^r(B_{p,q}^{\theta^*})} \|\rho_{t, \mu}\|_{L^r(B_{p,q}^{\theta^*})} \rho_{t, \mu}^{\varepsilon_k}.
\]

Using Lemma 8 and Proposition 2 we conclude that \(\|\Delta^2_{\rho_{t, \mu}} \rho_{t, \mu}^{\varepsilon_k} (\varphi)\| \rightarrow 0\) so that \(\rho_{t, \mu}\) satisfies (1.19) in a distributional sense.

To establish the Duhamel representation (1.18) observe first that for any \(s \in [t, T], \varphi \in C_0^\infty((-T, T) \times \mathbb{R}^d)\),

\[
\int \mathbb{R}^d dy \rho_{t, \mu}^{\varepsilon_k}(s, y) \varphi(s, y) - \int \varphi(t, y) \mu(dy) - \int_t^s dv \int \mathbb{R}^d dy \{ \mathcal{B}_{t, \mu}^{\varepsilon_k}(v, y) \rho_{t, \mu}^{\varepsilon_k}(v, y) \} \cdot \nabla \varphi(v, y) + \int_t^s dv \int \mathbb{R}^d dy \rho_{t, \mu}^{\varepsilon_k}(v, y) (\partial_s - (L^\alpha)^*) \varphi(v, y) = 0.
\]
Introducing
\[\Delta_{\rho,\mu}^s \varphi := \int_{\mathbb{R}^d} dy (\rho^s_{t,\mu} - \rho_{t,\mu})(s, y) \varphi(s, y)\]
\[- \int_t^s dv \int_{\mathbb{R}^d} dy \left\{ B^s_{t,\mu}(v, y) \rho^s_{t,\mu}(v, y) - B_{t,\mu}(v, y) \rho_{t,\mu}(v, y) \right\} \cdot \nabla \varphi(v, y)\]
\[+ \int_t^s dv \int_{\mathbb{R}^d} dy (\rho^s_{t,\mu}(v, y) - \rho_{t,\mu}(v, y))(-\partial_s + (L^\alpha)^*) \varphi(v, y),\]
it can hence be deduced from the previous arguments that, along a suitable subsequence \((\varepsilon_{km})_{m \geq 1}\) (to handle the first additional term through the converse of the Lebesgue theorem from the strong convergence \((3.14)\)), that \(\Delta_{\rho,\mu}^s \varphi \to 0\) for almost all \(s \in [t, T]\). Hence, from \((3.20)\), for almost all \(s \in [t, T]\),
\[
\int_{\mathbb{R}^d} dy \rho_{t,\mu}(s, y) \varphi(s, y) - \int \varphi(t, y) \mu(dy) - \int_t^s dv \int_{\mathbb{R}^d} dy B_{t,\mu}(v, y) \rho_{t,\mu}(v, y) \cdot \nabla \varphi(v, y) + \int_t^s dv \int_{\mathbb{R}^d} dy \rho_{t,\mu}(v, y)(-\partial_s + (L^\alpha)^*) \varphi(v, y) = 0.
\]
The representation \((1.18)\) is then finally derived from \((3.21)\) following mostly the arguments of the proof of Lemma 3 (see Appendix B). The essential difference being that the Duhamel formulation \((1.16)\) is derived therein from a non-uniform estimate for \(|b|^\|L^\infty(\mathbb{R}^d)\|\) which has to be replaced here by the control of \(|b|L^\infty(B^\beta_{p',q'})\). Taking \(\phi(v, x) = p^\alpha_{s-v} \ast f(x)\) with \(f \in C_0^\infty((-T, T) \times \mathbb{R}^d)\) in \((3.21)\) yields
\[
\int_{\mathbb{R}^d} dy f(y) \rho_{t,\mu}(s, y) = \int p^\alpha_{s-v} \ast f(y) \mu(dy) + \int_t^s dv \int_{\mathbb{R}^d} dy \left\{ B_{t,\mu}(v, y) \rho_{t,\mu}(v, y) \right\} \cdot \nabla \varphi(v, y).
\]
As \(\rho_{t,\mu} \in L^\infty(B^\beta_{p',q'})\) and \(|\rho_{t,\mu}(v, \cdot)|_{L^1} = 1\), applying successively \((HK)\) and \((Y)\), we get from the condition \((C0)\):
\[
\int_t^s dv \int dy \int dz |f(z)| ||\nabla p^\alpha_{s-v}(y - z)||B_{t,\mu}(v, y) ||\rho_{t,\mu}(v, y)|| \leq |f|L^\infty \left( \int_t^s \frac{dv}{(s-v)^\alpha} |\rho_{t,\mu}(v, \cdot)|_{B^\beta_{p',q'}} \right)^\frac{\alpha}{\alpha-1} \leq C |f|L^\infty,
\]
using Lemmas \((7)\) and \((8)\) for the last inequality. Following the arguments of Lemma 3 the class of functions \(f\) can thus be extended to any bounded measurable function. In turn, this extension gives \((1.18)\).

We complete this section with a uniqueness result for \((1.18)\) in \(L^\infty(B^\beta_{p',q'})\), with \(\varphi\) as in \((3.1)\), \(\vartheta \in [0, 1]\), which, with the preceding lemma, yields to the well-posedness result stated in Proposition 6.

**Lemma 10.** For any \((t, \mu) \in [0, T] \times \mathcal{P}(\mathbb{R}^d)\), the non-linear Fokker-Planck equation \((1.19)\) admits a unique solution \((\rho_{t,\mu}(s, \cdot))_{s \in [t, T]} \in L^\infty(B^\beta_{p',q'})\) with \(\varphi\) as in \((3.1)\), \(\vartheta \in [0, 1]\) and \(\Gamma\) given by \((C)\), s.t. for all \(s \in [t, T]\), \(\rho_{t,\mu}(s, \cdot) \in \mathcal{P}(\mathbb{R}^d)\).

**Proof.** Assume that \(\rho^{(1)}_{t,\mu}\) and \(\rho^{(2)}_{t,\mu}\) are two possible solutions of \((1.19)\). From the last part of the proof of Lemma 5 one can easily check that density functions solving \((1.19)\), and which lie in \(L^\infty(B^\beta_{p',q'})\), also satisfy the Duhamel formulation \((1.18)\). Then, for a.e. \(t \leq s \leq T\), \(y \in \mathbb{R}^d\),
\[
\rho^{(1)}_{t,\mu}(s, y) - \rho^{(2)}_{t,\mu}(s, y) = - \int_t^s dv \left\{ B_{t,\mu}(v, \cdot) \rho^{(1)}_{t,\mu}(v, \cdot) - B_{t,\mu}(v, \cdot) \rho^{(2)}_{t,\mu}(v, \cdot) \right\} \cdot \nabla p^\alpha_{s-v}(y, \cdot).
\]
Reproducing the stability arguments of the proof of Lemma 8 (see in particular those leading to \((3.16)\)), one can check that
\[
|\rho^{(1)}_{t,\mu}(s, \cdot) - \rho^{(2)}_{t,\mu}(s, \cdot)|_{B^\beta_{p',q'}} \leq C \int_t^s \frac{dv}{(s-v)^\alpha} |b(v, \cdot)|_{B^\beta_{p',q'}} \left\{ |\rho^{(1)}_{t,\mu}(v, \cdot)|_{B^\beta_{p',q'}} |\rho^{(1)}_{t,\mu}(v, \cdot) - \rho^{(2)}_{t,\mu}(v, \cdot)|{|}_{L^1} + |\rho^{(1)}_{t,\mu}(v, \cdot) - \rho^{(2)}_{t,\mu}(v, \cdot)|_{B^\beta_{p',q'}} \right\}.
\]
On the one hand, since $\mu^{(1)}_{t,\mu}$ satisfies (1.18), the analysis of Lemma 7 can be reproduced and the controls stated therein remain valid with $\mu^{(1)}_{t,\mu}$ replaced by $\mu^{(2)}_{t,\mu}$. In particular:

$$\left( \int_t^s \frac{dv}{(s-v)^{\alpha+\beta}} |\mu^{(1)}_{t,\mu}(v,\cdot)|_{B^\alpha_{p,q,v}} \right) \leq C(s-t)^\theta. $$

On the other hand, the analysis of Lemma 8 can be reproduced to control the term $|\mu^{(1)}_{t,\mu}(v,\cdot) - \mu^{(2)}_{t,\mu}(v,\cdot)|_{L^1}$. In particular, similarly to (3.17), one gets:

$$\sup_{v \in (t,s)} \{ |\mu^{(1)}_{t,\mu}(v,\cdot) - \mu^{(2)}_{t,\mu}(v,\cdot)|_{L^1} \} \leq C |b|_{L^r(B^\alpha_{p,q,v})} \sup_{v \in (t,s)} \| (\mu^{(1)}_{t,\mu} - \mu^{(2)}_{t,\mu}) \|_{L^r((t,v) \setminus B^{-\alpha}_{p,q,v})},$$

and similarly to (3.19) one can show that it holds:

$$\sup_{v \in (t,T)} \| (\mu^{(1)}_{t,\mu} - \mu^{(2)}_{t,\mu}) \|_{L^r((t,v) \setminus B^{-\alpha}_{p,q,v})} = 0.$$ 

Hence, $\sup_{v \in (t,T)} \{ |\mu^{(1)}_{t,\mu}(v,\cdot) - \mu^{(2)}_{t,\mu}(v,\cdot)|_{L^1} \} = 0$ and

$$|\mu^{(1)}_{t,\mu}(s,\cdot) - \mu^{(2)}_{t,\mu}(s,\cdot)|_{B^{-\alpha}_{p,q,v}} \leq C \int_t^s \frac{dv}{(s-v)^{\alpha+\beta}} |b(v,\cdot)|_{B^\alpha_{p,q,v}} |\mu^{(1)}_{t,\mu}(v,\cdot) - \mu^{(2)}_{t,\mu}(v,\cdot)|_{B^{-\alpha}_{p,q,v}} \right) \leq C |b|_{L^r(B^\alpha_{p,q,v})} \left( \int_t^s \frac{dv}{(s-v)^{\alpha+\beta}} \right)^\theta. $$

Taking the $\tilde{r}$ exponent, integrating in time and using the Hölder inequality and the Fubini theorem yield the statement. These arguments are similar to those at the end of the proof of Lemma 8.

\[\Box\]

### 3.2. From the Fokker-Planck equation to the martingale problem.

To prove the weak well-posedness part of Theorem 11, it remains to relate the non-linear Fokker-Planck equation to the non-linear martingale problem.

We first establish the existence of a weak solution to (1.14) taking any limit point of a converging subsequence of $P^\epsilon$, solution to the non-linear martingale problem related to the mollified McKean-Vlasov SDE (1.13). The uniqueness of the solution will then be derived through an enhanced (to the stable pure jump case) Krylov-Röckner like criterion. Both results preliminary rely on a uniform estimate for the mollified non-linear drift $B^\epsilon_{t,\mu}$ involved in (1.18) which, collecting the estimates established in Section 3.1, reads as follows:

**Lemma 11.** Assume that (C0) holds. For any $(t,\mu)$ in $[0,T] \times \mathcal{P}(\mathbb{R}^d)$, any $\epsilon > 0$, the mollified non-linear drift $B^\epsilon_{t,\mu}$ in (1.13) is in $L^\infty(B^0_{\infty,1})$ for all $r_0$ in $\left(0,\left(\frac{1}{\epsilon + \frac{1}{\tilde{r}}}\right)^{-1}\right)$, for $\tilde{r}$ satisfying (3.11) and the following estimate holds:

$$\forall t \leq S \leq T, \ |B^\epsilon_{t,\mu}|_{L^\infty((t,S) \setminus B^0_{\infty,1})} \leq C(S-t)^{\frac{1}{\tilde{r}_0} - \frac{1}{\tilde{r}}}. $$

**Proof.** From the Young inequality (Y), one gets for all $s \in (t,T)$:

$$|B^\epsilon_{t,\mu}(s,\cdot)|_{B^0_{\infty,1}} \leq C_\epsilon |\rho^\epsilon_{t,\mu}(s,\cdot)|_{B^\alpha_{p,q,v}}. $$

Take now $r_0$ as indicated, then $r > r_0$ and use the Hölder inequality to derive:

$$|B^\epsilon_{t,\mu}|_{L^\infty((t,S) \setminus B^0_{\infty,1})} \leq C_\epsilon |\rho^\epsilon_{t,\mu}(s,\cdot)|_{B^\alpha_{p,q,v}} \left( \int_t^S ds |\rho^\epsilon_{t,\mu}(s,\cdot)|_{B^\alpha_{p,q,v}} \right)^\frac{1}{\tilde{r}_0} \left( T - s \right)^{\frac{1}{\tilde{r}_0} - \frac{1}{\tilde{r}}}. $$

Since $r_0 \in \left(0,\left(\frac{1}{\epsilon + \frac{1}{\tilde{r}}}\right)^{-1}\right)$, then $\tilde{r} \geq \frac{r_0}{r-r_0}$. If the equality holds the claim directly follows from Lemma 7.

If $\tilde{r} > \frac{r_0}{r-r_0}$ an additional Hölder inequality in time is needed. Indeed,

$$|B^\epsilon_{t,\mu}|_{L^\infty((t,S) \setminus B^0_{\infty,1})} \leq C_\epsilon |\rho^\epsilon_{t,\mu}(s,\cdot)|_{B^\alpha_{p,q,v}} \left( \int_t^S ds |\rho^\epsilon_{t,\mu}(s,\cdot)|_{B^\alpha_{p,q,v}} \right)^\frac{1}{\tilde{r}_0} \left( T - s \right)^{\frac{1}{\tilde{r}_0} - \frac{1}{\tilde{r}}}. $$

\[\Box\]
Existence results. We recall that a measure \( P \) (a probability measure on the canonical space \( \Omega_\alpha \)) solves the non-linear martingale problem related to \((\ref{mpnl})\) on \([t, T]\) if:

(i) \( P \circ x(t)^{-1} = \mu; \)

(ii) for a.a. \( s \in (t, T], \) \( P \circ x(s)^{-1} \) is absolutely continuous w.r.t. Lebesgue measure and its density belongs to \( L^r((t, T], B_{p,q}^r). \)

(iii) for all \( f \) in \( C^1([t, T], C_0^\infty(\mathbb{R}^d)) \), the process

\[
\left\{ f(s, x(s)) - f(t, x(t)) - \int_t^s (\partial_x f(v, x(v)) + B_{\rho x(v)}(v, x(v)) \cdot \nabla f(v, x(v)) + L^\alpha(f)(v, x(v))) \, dv \right\}_{t \leq s \leq T}
\]

is a \( P \) martingale.

Remark 3. We point out that in our singular drift setting it is rather natural to require some smoothness properties on the marginal laws of the canonical process of \( P \). Those are precisely the ones which allow to define properly almost everywhere the non-linear drift in \((\text{MP}_\text{NL})\). Pay attention anyhow that even in this setting \( B_{\rho x(v)}(v, x(v)) \) is still potentially singular in time and we cannot directly appeal to well known results to ensure well-posedness.

Also, we will in the following identify the marginal law and its density, i.e. if \( P(x(v) \in dx) := P_{\tau, \mu}(v, dx) = \rho_{\tau, \mu}(v, x) dx \), then we denote \( B_{\rho x(v)}(v, \cdot) = B_{\rho x(v)}(v, \cdot). \)

Proposition 12. Under the assumption \((C0)\), the solution to the non-linear martingale problem related to \((\ref{mpnl})\) converges, in \( P(\Omega_\alpha) \) equipped with its weak topology, to a solution to the non-linear martingale problem related to \((\ref{mpnl})\).

Proof of Proposition \((12)\) Let \((P^\varepsilon)_{\varepsilon>0}\) be the sequence of solutions to the non-linear martingale problem related to \((\ref{mpnl})\).

Tightness. According to the Aldous tightness criterion (e.g. \cite{6} Theorem 16.10) if \( \alpha < 2 \) or the Kolmogorov one if \( \alpha = 2 \) \cite{6} Theorem 7.3, and as neither the initial condition \( \xi \) nor the diffusion component \( W \) are affected by the mollification, establishing the tightness of \((P^\varepsilon)_{\varepsilon>0}\) reduces to show the uniform (w.r.t. \( \varepsilon \)) almost-sure continuity of \( s \mapsto \int_0^s \rho^\varepsilon_{\tau, \mu}(v, X^\varepsilon_{\tau, \mu}) dv \). In view of \((3.22)\) this property is immediately fulfilled.

Limit points. Let \((P^\varepsilon)_{\varepsilon_k}\) be a converging subsequence and let \( P \) be its limit. In addition to the weak convergence of \((P^\varepsilon)_{\varepsilon_k}\) towards \( P \), according to Lemma \((8)\) the marginal distributions \( (P^\varepsilon)_{\varepsilon_k}(s, dx) = \rho^\varepsilon_{\tau, \mu}(s, x) \) converge strongly towards \( P_{\tau, \mu}(s, dx) = \rho_{\tau, \mu}(s, x) dx \) in \( L^r(B_{p,q}^r) \). This strong convergence implies the convergence of \((B^\varepsilon_{\rho^\varepsilon_{\tau, \mu}})_{\varepsilon_k}\) towards \( B_{\rho_{\tau, \mu}} \) in \( L^\infty(L^0) \). Indeed, for \( \tau_0 \) as in \((3.22)\), and proceeding as in the proof of Lemma \((11)\)

\[
|B^\varepsilon_{\rho^\varepsilon_{\tau, \mu}} - B_{\rho_{\tau, \mu}}|_{L^\infty(L^0)} \leq C|B^\varepsilon_{\rho^\varepsilon_{\tau, \mu}} - B_{\rho_{\tau, \mu}}|_{L^0(B^\infty_{p,q})}
\]

\[
\leq C \left( |\rho^\varepsilon_{\tau, \mu}|_{L^r(B_{p,q}^r)} |B^\varepsilon_{\rho^\varepsilon_{\tau, \mu}}|_{L^r(B_{p,q}^r)} + |b|_{L^r(B_{p,q}^r)} |\rho^\varepsilon_{\tau, \mu} - \rho_{\tau, \mu}|_{L^r(B_{p,q}^r)} \right) \rightarrow_\varepsilon 0,
\]

where, as in the proof of Lemma \((8)\) \( r = r \) if \( r < +\infty \) and any finite \( \tilde{r} \) large enough if \( r = +\infty \), i.e. the conjugate exponent \( r^* \) belongs to the interval indicated after \((3.2)\). The previous convergence follows from Proposition \((2)\) and Lemmas \(7\) and \(8\).

This also yields, as a natural extension, the variational limit. For all \( \Phi \in C^\infty((t, T) \times \mathbb{R}^d,\mathbb{R}^d) \),

\[
\lim_{k \rightarrow \infty} \int_t^T \int B^\varepsilon_{\rho^\varepsilon_{\tau, \mu}}(s, x) \cdot \Phi(s, x) \, dx \, ds = \int_t^T \int B_{\rho_{\tau, \mu}}(s, x) \cdot \Phi(s, x) \, dx \, ds.
\]

This last convergence is sufficient to ensure that (e.g. \cite{25} Lemma 5.1): for any \( 0 \leq t_1 \leq \cdots \leq t_i \leq \cdots \leq t_n \leq t \leq T, \Psi_1, \cdots, \Psi_n \) continuous bounded, and for any \( \phi \) of class \( C^\infty_0(\mathbb{R}^d,\mathbb{R}) \),

\[
\mathbb{E}_{\rho_{\tau, \mu}} \left[ \prod_{i=1}^n \mathbb{E}_{\tau, \mu}(t_i) \int_t^T B^\varepsilon_{\rho^\varepsilon_{\tau, \mu}}(s, x(s)) \cdot \nabla \phi(x(s)) \, ds \right] \rightarrow_k \mathbb{E}_{\rho_{\tau, \mu}} \left[ \prod_{i=1}^n \mathbb{E}_{\tau, \mu}(t_i) \int_t^T B_{\rho_{\tau, \mu}}(s, x(s)) \cdot \nabla \phi(x(s)) \, ds \right].
\]

This precisely gives that \( P \) is solution of the non-linear martingale problem related to \((\ref{mpnl})\). \(\square\)
Weak uniqueness results.

**Proposition 13** (Uniqueness result). Under the assumption \([C0]\), for any \((t, \mu)\) in \([0, T] \times \mathcal{P}(\mathbb{R}^d)\) the SDE \([11]\) admits at most one weak solution s.t. its marginal laws \(\{\mu_{s,t}(\cdot)\}_{s \in [t, T]}\) have a density for a.e. \(s \in (t, T)\), i.e. \(\mu_{s,t}(dx) = \rho_{t,\mu}(s, x)dx\) and \(\rho_{t,\mu} \in L^1(B_{p,q}^{\beta/\alpha})\) for any \(\bar{r}\) satisfying \([3.1]\).

**Proof.** According to Proposition [5], any pair of solutions to the non-linear martingale problem related to \([11]\) whose (time) marginal distributions lie in \(L^1(B_{p,q}^{\beta/\alpha})\) have the same marginal distributions. The non-linear drift \(B_{\rho_{t,\mu}}(s, \cdot)\) is therefore, for a.e. \(s \in [t, T]\), given by \(b(s, \cdot) + \rho_{t,\mu}(s, \cdot)\), \(\rho_{t,\mu}\) being the unique solution in \(L^1(B_{p,q}^{\beta/\alpha})\) of the non-linear Fokker-Planck equation \([1.19]\). As \(\rho_{t,\mu}\) is in \(L^1(B_{p,q}^{\beta/\alpha})\), one can further check that, similarly to \([3.22]\):

\[
|B_{\rho_{t,\mu}}|_{L^r((t,T),B^0_{p,q})} \leq c \gamma |b|_{L^r(B_{p,q}^{\beta/\alpha})} \rho_{t,\mu}^{1/2} \rho_{t,\mu}^{1/2} \leq c \gamma |b|_{L^r(B_{p,q}^{\beta/\alpha})} \rho_{t,\mu}^{1/2} \rho_{t,\mu}^{1/2},
\]

for any \(r \) and \(\bar{r}\) such that \((r) = (\bar{r})^{-1} + (r)^{-1}\) and \(r' \leq \bar{r} < (\beta/\alpha + d/\alpha)^{-1}\). Thus, the drift \(B_{\rho_{t,\mu}}\) in \([11]\) is well defined and all weak solutions to \([11]\) whose density belongs to \(L^1(B_{p,q}^{\beta/\alpha})\) share the same drift \(B_{\rho_{t,\mu}}\). Uniqueness of the non-linear martingale problem thus follows from uniqueness of the solution \(P\) (a probability measure on the canonical space \(\Omega_s\)) to the (linear) martingale problem related to \((\mu, L^\alpha, F)\), where \(F = B_{\rho_{t,\mu}}\), defined as:

(i) \(P \circ x(t)^{-1} = \mu;\)

(ii) for a.a. \(s \in (t, T]\), \(P \circ x(s)^{-1}\) is absolutely continuous w.r.t. Lebesgue measure;

(iii) for all \(f \in C^1([t, T], C^1_0(\mathbb{R}^d))\), the process

\[
\left\{ f(s, x(s)) - f(t, x(t)) - \int_t^s \left( \partial_v f(v, x(v)) + F(v, x(v)) \cdot \nabla f(v, x(v)) + L^\alpha(f)(v, x(v)) \right) dv \right\}_{t \leq s \leq T},
\]

is a \(P\) martingale.

The following Lemma gives sufficient condition for the solution to the (linear) martingale problem \([MP]\) to be unique.

**Lemma 14.** Assume that \(F\) is in \(L^\alpha(L^\infty)\) with \(1 \leq \alpha \leq \infty\) and

\[
\alpha < \alpha - 1.
\]

Then the (linear) martingale problem related to the triplet \((\mu, L^\alpha, F)\) admits at most one solution.

To conclude, it thus only remains to check whether the condition stated in the above Lemma is satisfied by the non-linear drift \(F = B_{\rho_{t,\mu}}\). This latter is immediately implied by \([3.23]\) as we have that \((s, x) \mapsto B_{\rho_{t,\mu}}(s, x)\) is in \(L^\alpha(B^0_{p,q})\) and, according to \([E1]\), in \(L^\alpha(L^\infty)\). From condition \([C0]\) and the definition of \(\Gamma\) in \([C1]\), taking \(\bar{r} \in \left( \frac{\alpha}{\alpha - \beta + 2p - \beta + 2p} \right)^{-1}, \left( \frac{\alpha}{\alpha - \beta + 2p} \right)^{-1} \right)\), \(\theta \in (0, 1)\), it hence holds that \(\alpha/\alpha < \alpha - 1\) which gives the previous criterion with \(\alpha = \alpha\).

**Remark 4.**

- (On the formulation of the linear martingale problem \([MP]\)). While the conditions \((i)\) and \((iii)\) are rather classical (see e.g. \([50, 25]\)), the condition \((ii)\) is enforced in order to exhibit a short demonstration for the uniqueness criterion stated in Lemma \([14]\) below. This condition enables notably to take advantage of the results obtained in \([20]\).

- (On the Krylov-Röckner like criterion in Lemma \([14]\)). The criterion \([3.24]\) is a particular case of a condition appearing in \([20]\). Namely, it was established in the quoted work a uniqueness result for a modified form of the (linear) martingale problem associated with a drift \(B_{\rho_{t,\mu}}\) in \(L^\alpha(B^0_{\mu,m})\) with \(m \in [1, \infty]\) and

\[
\beta_{lin} \in \left( \frac{1}{2} \left(1 - \alpha - d \right) + \frac{\alpha}{\alpha - 1}\right), 0 < \beta_{lin} < 0.
\]

The restriction \(\beta_{lin} < 0\) in this paper was essentially motivated to emphasize the distributional setting. However, the arguments and techniques initially introduced in \([20]\) can be adapted to handle the case \(\beta_{lin} = 0\). This precisely allows to derive a weak uniqueness result for a "classical"
martingale problem under the aforementioned Krylov-Röckner type criterion (3.24). This is the purpose of Lemma 14.

Proof of Lemma 14. According to (E1), the statement of the lemma will follow if we prove it for a drift $F$ in $L^2((t, T], B^0_{\infty, 1})$. Taking $\varepsilon = 1 - \gamma > 0$, meant to be very small, with

$$\gamma \in \left[\frac{1}{2}, (3 - \alpha + \frac{\alpha}{\beta}), 1\right] \Rightarrow 1 - \gamma \in \left(0, \frac{1}{2}(\alpha - 1 - \frac{\alpha}{\beta})\right),$$

we further recover the initial setting of [20], i.e. from (E2) $F \in L^2((t, T], B^0_{\infty, 1})$. (Importantly, it is precisely the condition (3.24) which allows this lifting.) Next, from Theorem 2 in [20], it follows that for any $t < T_0 < \infty$ and any smooth bounded function $h$ on $[t, T_0] \times \mathbb{R}^d$, the backward PDE

$$\begin{aligned}
\partial_s u + F \cdot Du + L^\theta u &= -h \text{ on } [t, T_0] \times \mathbb{R}^d, \\
u(T_0, \cdot) &= 0,
\end{aligned}$$

admits a unique bounded (mild) solution in $C^{0,1}((0, T_0] \times \mathbb{R}^d, \mathbb{R})$ for which $Du \in C^{0,1}((0, T_0], B^{\theta - 1 - \varepsilon'}_{\infty, \infty})$ for $\theta := 1 - \gamma - 1 - \alpha - \alpha/\beta$ and for any $\varepsilon' > 0$, again meant to be small such that $\theta - 1 - \varepsilon' > 0$ (this can be achieved from (3.24) which gives $\theta - 1 = (\gamma - 1) + \alpha - \alpha/\beta - 1 > 1 - \gamma = \varepsilon$ for $\varepsilon$ small enough and taking $\varepsilon' = \varepsilon$). In particular $u$ satisfies: for all $\varphi$ in $C^{0,1}((t, T_0] \times \mathbb{R}^d)$,

$$\int_t^{T_0} ds \int dx \left[ u(s, x)(\partial_s - L^\theta)(\varphi)(s, x) - \left(F(s, x) \cdot Du(s, x)\right)\varphi(s, x) - h(s, x)\varphi(s, x)\right] = 0.$$

Note that, according to the control previously obtained in [20], and as $F$ is here in $L^2((t, T], B^0_{\infty, 1})$, the first order term, $(F \cdot Du) \varphi$, is well-defined. Introduce now $\{\phi_n\}_n$, a sequence of compactly supported time-space mollifiers such that, for all $n$, $\phi_n(\cdot) = n^{-d}\phi(n^{-1} \cdot)$ where $\phi$ is a symmetric, non-negative function, equal to 1 on the unit ball of $\mathbb{R}^{d+1}$ and s.t. $\int ds \int dz \phi(s, z) = 1$. Setting $u_n = \phi_n \otimes u$ - where, borrowing the notation of [20], $\otimes$ stands for the time-space convolution product - we now claim that: $\mathbb{P}^i$-a.s. (for $i = 1, 2$), $s \leq T_0$,

$$\int_s^{T_0} \left(\partial_v + F \cdot D + L^\alpha\right)u_n(v, x(v)) \, dv = -\int_s^{T_0} h_n(v, x(v)) \, dv + \int_s^{T_0} R_n(v, x(v)) \, dv,$$

where $h_n = \phi_n \otimes h$ and

$$R_n(v, x) := F(v, x) \cdot Du_n(v, x) - \phi_n \otimes \left(F \cdot Du\right)(v, x).$$

This expression arises from writing the action of the differential operator on $u_n$ which gives, for all $(v, x)$ in $[t, T_0] \times \mathbb{R}^d$,

$$\begin{aligned}
(\partial_v + F(v, x) \cdot D + L^\alpha)(u \otimes \phi_n(v, x)) &= (\partial_v + F(v, x) \cdot D + L^\alpha)\left(\int dw \int dz u(w, z)\phi_n(v-w, x-z)\right) \\
&= \int dw \int dz u(w, z)\left(\partial_v + F(v, x) \cdot D + L^\alpha\right)\phi_n(v-w, x-z) \\
&= \int dw \int dz u(w, z)\left(-\partial_w + L^\alpha\right)\phi_n(v-w, x-z) - \int dw \int dz u(w, z)F(v, x) \cdot (D_v \phi_n)(v-w, x-z) \\
&= -\int dw \int dz \left(F(w, z) \cdot Du(w, z) + h(w, z)\right) \phi_n(v-w, x-z) \\
&= \int dw \int dz \left[F(v, x) - F(w, z)\right] \cdot Du(w, z) \phi_n(v-w, x-z) - h_n(v, x).
\end{aligned}$$

The last equality follows from an integration by parts. The symmetry of $\phi_n$ eventually brings

$$\int dw \int dz \left[F(v, x) - F(w, z)\right] \cdot Du(w, z) \phi_n(v-w, x-z) = F(v, x) \cdot Du_n(v, x) - \phi_n \otimes \left(F \cdot Du\right)(v, x).$$
Let now $\mathbf{P}_1$ and $\mathbf{P}_2$ be two solutions to the martingale problem related to $(\mu, L^\alpha, F)$. Denoting by $\mathbf{P}_i^{u,x_0}$ the conditional probability of $\mathbf{P}_i^{u,x_0}$ given \{x(s) = x_0\}, and taking $f(s,x) = u_n(s,x)$ in (MP), it follows that, for $i = 1, 2$,

$$\mathbb{E}_{\mathbf{P}_i^{u,x_0}} \left[ u_n(T_0, x(T_0)) + \int_{s}^{T_0} h_n(v, x(v)) \, dv \right] - u_n(s, x_0) = \mathbb{E}_{\mathbf{P}_i^{u,x_0}} \left[ \int_{s}^{T_0} R_n(v, x(v)) \, dv \right]. \quad (3.25)$$

Letting $n$ tend to infinity, by continuity and boundedness of $u$, $u_n(T_0, x(T_0))$ converges a.s. to $0$ as well as $\mathbb{E}[u_n(T_0, x(T_0))]$ (0 is the terminal condition of the backward equation). Similarly, $u_n(s, x_0)$ converges to $u(s, x_0)$. Also, again by continuity and boundedness of $h$,

$$\lim_{n} \mathbb{E}_{\mathbf{P}_i^{u,x_0}} \left[ u_n(T_0, x(T_0)) + \int_{s}^{T_0} h_n(v, x(v)) \, dv \right] - u_n(s, x_0) = \mathbb{E}_{\mathbf{P}_i^{u,x_0}} \left[ \int_{s}^{T_0} h(v, x(v)) \, dv \right] - u(s, x_0). \quad (3.26)$$

We next claim that

$$\lim_{n} \mathbb{E}_{\mathbf{P}_i^{u,x_0}} \left[ \int_{s}^{T_0} R_n(v, x(v)) \, dv \right] = 0. \quad (3.27)$$

To check this claim, following (ii) denote by $\varphi^i(s, x_0; v, \cdot)$ the density function of the canonical process of $\mathbf{P}_i^{u,x_0}$ at time $v$, and observe now that:

$$\mathbb{E}_{\mathbf{P}_i^{u,x_0}} \left[ \int_{s}^{T_0} R_n(v, x(v)) \, dv \right] = 0.$$

Applying then the Hölder inequality, we derive

$$\left| \int_{s}^{T_0} \mathbb{E}_{\mathbf{P}_i^{u,x_0}} \left[ \int_{s}^{T_0} R_n(v, x(v)) \, dv \right] \right| = \left| \int_{s}^{T_0} \mathbb{E}_{\mathbf{P}_i^{u,x_0}} \left[ \int_{s}^{T_0} R_n(v, x(v)) \, dv \right] \right| \leq \int_{s}^{T_0} \mathbb{E}_{\mathbf{P}_i^{u,x_0}} \left[ \int_{s}^{T_0} R_n(v, x(v)) \, dv \right] \leq C|u^i(s, x_0; \cdot; \cdot)|_{\alpha, \vartheta} \rightarrow 0.$$

Applying then the Hölder inequality, we derive

$$\left| \int_{s}^{T_0} \mathbb{E}_{\mathbf{P}_i^{u,x_0}} \left[ \int_{s}^{T_0} R_n(v, x(v)) \, dv \right] \right| \leq \left| F \right|_{L^\infty} \left( \int_{s}^{T_0} \mathbb{E}_{\mathbf{P}_i^{u,x_0}} \left[ \int_{s}^{T_0} R_n(v, x(v)) \, dv \right] \right)^{1/\alpha} \leq \left| F \right|_{L^\infty} \left( \int_{s}^{T_0} \mathbb{E}_{\mathbf{P}_i^{u,x_0}} \left[ \int_{s}^{T_0} R_n(v, x(v)) \, dv \right] \right)^{1/\alpha} \leq \left| F \right|_{L^\infty} \left( \int_{s}^{T_0} \mathbb{E}_{\mathbf{P}_i^{u,x_0}} \left[ \int_{s}^{T_0} R_n(v, x(v)) \, dv \right] \right)^{1/\alpha} \leq C|u^i(s, x_0; \cdot; \cdot)|_{\alpha, \vartheta} \rightarrow 0.$$

To handle the second term in the r.h.s. of (3.27) we will use the continuity property of the shift operator for Lebesgue norms: for $f \in L^\infty(\mathbb{R}, L^\alpha)$ with $\ell \leq \ell < \infty$, $1 \leq \alpha < \infty$ - non-necessarily equal - the mapping
Now, extending by zero \( g^\ell(s,x_0;\cdot,\cdot) \) outside \([t,T] \times \mathbb{R}^d\), \( g^\ell(s,x_0;\cdot,\cdot) \) can be viewed as an element of \( L^2(L^1) \) and so

\[
\left| \int_s^{T_0} dv \int dy F(v,y) \cdot Du(v,y) \left[ \phi_n \land g^\ell(s,x_0;\cdot,\cdot)(v,y) \right] \right| \\
\leq |F|_{L^2(L^\infty)} |Du|_{L^2(L^\infty)} \left( \int_s^{T_0} dv \left( \int dy \left| \phi_n \land g^\ell(s,x_0;\cdot,\cdot)(v,y) \right| \right)^{1/\beta'} \right) \xrightarrow{n \to \infty} 0,
\]

which, together with (3.28), gives (3.27).

Consecutively, for \( i = 1 \) or \( i = 2 \), the quantity

\[
\mathbb{E}_{P_{\gamma,\ell,0}} \left[ \int_s^{T_0} h(v,x(v)) \, dv \right]
\]

is uniquely given by \( u(s,x_0) \) (passing to the limit in (3.25)). As \( h \) can be taken in a determining class for probability measures, this grants immediately the equality of the marginal distributions of \( P_1 \) and \( P_2 \), and by extension (see e.g. [20], Section 2.2, item (iii)) the equality \( P_1 = P_2 \) on \( \Omega_\alpha \).

\[\square\]

### 3.3. On strong solutions

The following Proposition gives conditions on the parameters that ensure existence and uniqueness of a strong solution for the McKean-Vlasov SDE (1.1) where the law is frozen. This thus ends up to prove that

\[
P \in P_{\gamma,\ell,0}
\]

Proof. As weak uniqueness holds, strong well-posedness follows from the strong well-posedness of the linear version of the McKean-Vlasov SDE (1.1) where the law is frozen. This thus ends up to prove that the drift

\[
b : [0,T] \times \mathbb{R}^d \ni (s,x) \mapsto b(s,x) = \int \mathbb{R}^d b(s,x-y)\mu^\ell(dx) = \int \mathbb{R}^d dy b(s,x-y)\rho_{\gamma,\ell}(s,y),
\]

satisfies a Krylov and Röckner type condition, see [42] if \( \alpha = 2 \), or the criterion in [61] Theorem 2.4] if \( \alpha \in (1,2) \). This can be summarized as follows:

(i) If \( \alpha = 2 \), then strong well-posedness holds if the drift \( b \) defined in (3.29) lies in \( L^2(L^4) \) with

\[
\frac{2}{\beta} + \frac{d}{\ell} < 1,
\]

(ii) If \( \alpha \in (1,2) \), then strong well-posedness holds if the drift \( b \) defined in (3.29) satisfies that (I – \( \Delta \))\( \gamma/2 \) \( b \) lies in \( L^2(L^4) \), or expressed equivalently in terms of Bessel potential space, \( b \in L^2(H^{\gamma/2}) \), where \( \gamma, \ell \) and \( \beta \) are such that

\[
\gamma \in \left( 1 - \frac{\alpha}{2}, 1 \right), \quad \ell \in \left( \frac{2d}{\alpha}, 2, \infty \right), \quad \beta \in \left( \frac{\alpha}{\alpha - 1}, \infty \right), \quad \frac{2}{\beta} + \frac{d}{\ell} < \alpha - 1.
\]

Note that the condition on \( b \) in (ii) will actually follow if we manage to prove that \( b \in L^2(B^\gamma_{1,1}) \). Indeed, \( B^\gamma_{1,2} \hookrightarrow H^{\gamma/2} \) when \( \ell \geq 2 \) (see e.g. [57] Th. 2.5.6 p.88 and [53] Rq.2 p.96) and we know from (E1) that for all \( \gamma > 0 \), \( B^\gamma_{1,1} \hookrightarrow B^\gamma_{1,2} \). Observing as well that, in the case \( \alpha = 2 \), since from (E1), (E2), \( B^\gamma_{1,1} \hookrightarrow B^0_{1,1} \hookrightarrow L^1 \), it suffices to prove that \( b \in L^2(B^\gamma_{1,1}) \) for \( \alpha \in (1,2] \) to ensure that both conditions (i) and (ii) hold.
Write now from (Y) and for ℓ meant to be large (but finite\(^4\)):

\[
|b(s, \cdot)|_{B^{\beta}_{\ell,1}} \leq |b(s, \cdot)|_{B^{\beta}_{p,q}} |\rho_{t,\mu}(s, \cdot)|_{B^{\gamma-\beta}_{2-\ell'}} , \quad \text{with } \ell_2 = p' - \frac{1}{p' + 1}.
\]

Note that one can choose any \(\ell_2 < p' \) close to \(p'\), since again \(\ell\) is arbitrarily large but finite. Write from the Hölder inequality,

\[
\int_{t}^{T} ds \, |b(s, \cdot)|_{B^{\beta}_{\ell,1}} \leq \left( \int_{t}^{T} ds \, |b(s, \cdot)|_{B^{\beta}_{p,q}}^{\alpha_0} \right)^{\frac{1}{\alpha}} \left( \int_{t}^{T} ds \, |\rho_{t,\mu}(s, \cdot)|_{B^{\gamma-\beta}_{2-\ell'}}^{\alpha} \right)^{\frac{1}{\gamma}} , \quad \alpha^{-1} + (\alpha')^{-1} = 1. \quad (3.31)
\]

We now claim that for all \(\varpi\) lying in the interval in (3.1),

\[
\forall \vartheta < p', \vartheta \in [0,1), \exists \theta > 0 \text{ s.t. } \int_{t}^{T} \, ds |\rho_{t,\mu}(s, \cdot)|_{B^{\vartheta}_{r,q}} \leq C(t - \theta)^{\theta}. \quad (*)
\]

As \(b \in L^{r}(t,T), B^{\beta}_{p,q})\), choosing now \(a\) such that \(\alpha = r\) which implies \(1/a' = 1 - 1/a = 1 - s/r \iff a' = r/(r - s), \gamma = \vartheta\) with \(\vartheta \in (0,1)\) and \(\ell\) large enough, the claim follows provided the set of parameters \(\vartheta, \ell\) and \(s = \varpi/a'\) satisfying (3.30) and the above condition is non-empty.

Firstly, the condition \(\varpi = \alpha'\) belongs to the interval in (3.1) writes

\[
\alpha' = \frac{r}{r - s} < \left( \frac{1}{\alpha} \left[ -\beta + \vartheta \Gamma + \frac{d}{p} \right] \right)^{-1} \iff \left( \frac{1}{\alpha} \left[ -\beta + \vartheta \Gamma + \frac{d}{p} \right] \right) r < \frac{r}{\delta} - 1
\]

\[
\implies s < r \left( 1 + \left( \frac{1}{\alpha} \left[ -\beta + \vartheta \Gamma + \frac{d}{p} \right] \right) r \right)^{-1}.
\]

Thus, if

\[
\frac{\alpha}{\alpha - 1} < r \left( 1 + \left( \frac{1}{\alpha} \left[ -\beta + \vartheta \Gamma + \frac{d}{p} \right] \right) r \right)^{-1}, \quad (S_1)
\]

there exists \(s\) satisfying the two last condition in (ii) and such that \(\varpi = \alpha'\) lies in the interval in (3.1). Indeed, since \(\ell\) can be taken arbitrarily large (but finite), the above condition allows to obtain

\[
\frac{\alpha}{\delta} + \frac{d}{\ell} < 1.
\]

As (S1) equivalently writes:

\[r \left( 1 - \frac{1}{\alpha} - \frac{1}{r} \right) > \left[ -\beta + \vartheta \Gamma + \frac{d}{p} \right] r \iff \beta > 1 - \alpha + \frac{d}{p} + \frac{\alpha}{r} + \vartheta \Gamma
\]

and, from the condition (C0) and the definition of (C), for all \(\vartheta \in [0,1)\) it holds

\[
\beta > 1 - \alpha + \frac{d}{p} + \frac{\alpha}{r} + \vartheta \Gamma,
\]

condition (S1) is always satisfied under our current assumptions.

Secondly, we need to check that

\[
\exists \vartheta \in (0,1) \text{ such that } \vartheta \Gamma = \gamma \in \left( 1 - \frac{\alpha}{2}, 1 \right).
\]

Under (C0s) - which matches (C0) in the case \(\alpha = 2\) - we have

\[
\Gamma = - \left( 1 - \alpha + \frac{d}{p} + \frac{\alpha}{r} \right) > 1 - \frac{\alpha}{2} \iff \beta > 2 - \frac{3\alpha}{2} + \frac{d}{p} + \frac{\alpha}{r},
\]

so that \(\vartheta\) can be taken sufficiently close to 1 in order to have \(\gamma = \vartheta \Gamma > 1 - \alpha/2\).

To conclude, it only remains to prove that (\(\star\)) holds true. Observe that for \(\alpha = 2\) and taking \(\ell = +\infty, \ell_2 = p'\) the control readily follows from the representation (1.18) in Proposition 8 and Lemmas 7.8. For \(\alpha \in (1,2)\), still starting from the representation (1.18) of \(\rho_{t,\mu}\), one may thus restart the proof of Lemma 7 up to (5.0) and choosing now therein \(\ell_2 < p'\) for the free integrability parameter, \(\gamma = -\beta + \vartheta \Gamma\). In such case, as \(\ell_2 < p'\), we obtain a lower singularity (in time) for the estimate of the first term in the

\(^{4}\text{we restrict here to a finite } \ell \text{ to consider the cases } \alpha = 2 \text{ and } \alpha \in (1,2) \text{ in a similar way. The case } \alpha = 2 \text{ could also be handled more directly considering } \ell = +\infty.\)
We first focus on the spatial approximation. Consider a time homogeneous kernel \( b \in B_{0,q}^\beta \) with \( \beta \in (-1,0] \), and define for \( \varepsilon > 0 \), \( b'(x) = \tilde{P}_\varepsilon b(x) = \tilde{p}^\alpha(v,\cdot) \ast b(x) \). We are going to prove that for all \( \beta < \beta' < \beta \) then
\[
|b' - b|_{B_{0,q}^\beta} \xrightarrow{\varepsilon \to 0} 0.
\]

To this aim, we first consider the thermic part \( T_{p,q}^\beta(b' - b) \) of \( |b' - b|_{B_{0,q}^\beta} \). For the proof we temporarily specify the notation of the operator \( T_{p,q}^\beta \) into \( T_{p,q,m}^\beta \) making the index \( n \) in (2.1) now explicit. As \( \beta < 0 \), \( n \) can be chosen freely over the set of non-negative integers, meanwhile, as \( b \) is in \( B_{0,q}^\beta \), \( T_{p,q,m}^\beta(b) \) \( \in \infty \) for any integer \( m > \beta \). In particular if \( \beta < 0 \) then \( m \geq 0 \) and we can choose \( m = n \geq 0 \), while if \( \beta = 0 \), it would be enough to consider the case \( n = 0, m = 1 \). But to keep the same parameters for all cases we first choose \( n = m = 1 \). We first assume \( \varepsilon < \infty \). Then,
\[
\left( T_{p,q,1}^\beta(b' - b) \right)^q := \int_0^1 \frac{dv}{v} v^{(1 - \frac{2}{\alpha})q} |\partial_\nu \tilde{p}^\alpha(v,\cdot) \ast (b_\varepsilon - b)|_{L_p}^q 
\leq 2^{q-1} \int_0^1 \frac{dv}{v} v^{(1 - \frac{2}{\alpha})q} \left( |\partial_\nu \tilde{p}^\alpha(v,\cdot) \ast b_\varepsilon|_{L_p}^q + |\partial_\nu \tilde{p}^\alpha(v,\cdot) \ast b|^q_{L_p} \right)
\leq 1 \int_0^1 \frac{dv}{v} v^{(1 - \frac{2}{\alpha})q} \left( |\partial_\nu \tilde{p}^\alpha(v,\cdot) \ast (b_\varepsilon - b)|_{L_p}^q \right)
\leq 2^q \left( 1 - \frac{\beta + \alpha}{\alpha} \right) \left( T_{p,q,1}^\beta(b) \right)^q \xrightarrow{\varepsilon \to 0} 0,
\]

since \( \beta < \beta' < \beta \).

Let us now turn to \( \mathcal{F}_2 \) for which we get:
\[
\mathcal{F}_2 \leq \int_0^1 \frac{dv}{v} v^{(1 - \frac{2}{\alpha})q} \left( \int_0^1 d\lambda \partial_\nu^2 \tilde{p}^\alpha(v + \varepsilon \lambda,\cdot) \ast b \right)_{L_p}^q 
\leq 2^q \left( 1 - \frac{\beta + \alpha}{\alpha} \right) \left( T_{p,q,1}^\beta(b) \right)^q \xrightarrow{\varepsilon \to 0} 0.
\]
Recall now from (E.1) and (Y) that:

$$\mid \partial^2_\phi \hat{p}(\theta,\cdot) \ast b \mid_{L^p} \leq \mid \partial^2_\phi \hat{p}(\theta,\cdot) \ast b \mid_{B^{\alpha}_{p,q}} \leq c\gamma \mid b \mid_{B^{\alpha}_{p,q}} \mid \partial^2_\phi \hat{p}(\theta,\cdot) \mid_{B^{-\beta}_{1,1}} \leq C \mid b \mid_{B^{\beta}_{p,q}} \delta^{-2-\beta},$$

which plugged into (A.4) yields:

$$\mathcal{F}_2 \leq 2\epsilon \frac{\delta^{2+\beta}}{\beta} \left[ \left( \mathcal{T}^{\beta}_{P,q,2}(b) \right) + C\epsilon \mid b \mid_{B^{\beta}_{p,q}} \right].$$

This together with (A.3), since $\mathcal{T}^{\beta}_{P,q,2}(b) < +\infty$, finally yields:

$$\left( \mathcal{T}^{\beta}_{P,q,1}(b^\epsilon - b) \right) \to 0 \quad \epsilon \to 0.$$  \hfill (A.5)

It is easily seen that the previous arguments can be adapted to the case $q = +\infty$, by modifying the decomposition (A.2) accordingly to the splitting

$$\mathcal{T}^{\beta}_{P,\infty,1}(b^\epsilon - b) := \sup_{v \in [0,1]} v^{(1-\frac{1}{p})} \mid \partial_v \hat{p}(v,\cdot) \ast (b^\epsilon - b) \mid_{L^p} \leq \sup_{v \in [0,2]} v^{(1-\frac{1}{p})} \mid \partial_v \hat{p}(v,\cdot) \ast (b^\epsilon - b) \mid_{L^p} + \sup_{v \in [2,1]} v^{(1-\frac{1}{p})} \mid \partial_v \hat{p}(v,\cdot) \ast (b^\epsilon - b) \mid_{L^p}.$$

Also, the last argument can be adapted to control the non-thermic part of the Besov norm. Namely,

$$\mid \hat{\phi} \ast (b^\epsilon - b) \mid_{L^p} = \mid (\hat{p}(\epsilon,\cdot) \ast \hat{\phi} - \hat{\phi}) \ast b \mid_{L^p} \leq C \mid b \mid_{B^{\beta}_{p,q}} \mid \hat{p}(\epsilon,\cdot) \ast (\hat{\phi} - \hat{\phi}) \mid_{B^{-\beta}_{1,1}} \to 0 \quad \epsilon \to 0.$$  \hfill (A.6)

from the smoothness of $\hat{\phi}$ and the continuity of the shift operator in $L^p$. The statement (A.1) eventually follows from (A.0) and (A.5). Moreover, as the by-product of the above arguments,

$$\mid \hat{b}(\epsilon) \mid_{B^{\beta}_{p,q}} \leq c\gamma \mid \hat{p}(\epsilon,\cdot) \mid_{B^{\beta}_{1,1}} \mid b \mid_{B^{\beta}_{p,q}} \leq c\gamma \mid \hat{p}(\epsilon,\cdot) \mid_{L^1} \mid b \mid_{B^{\beta}_{p,q}} = c\mid b \mid_{B^{\beta}_{p,q}}$$

for all $\epsilon > 0$.

Consider now a time dependent drift i.e. $b \in L^r([t,T],B^{\beta}_{p,q})$. Then for almost any $s \in (t,T)$, $b(s,\cdot) \in B^{\beta}_{p,q}$.

Thus, setting $b^{\epsilon}_{sp}(s,\cdot) = \tilde{P}_b \ast b(s,\cdot)$, we have

$$\mid b^{\epsilon}_{sp}(s,\cdot) \ast b(s,\cdot) \mid_{B^{\beta}_{p,q}} \to 0 \quad \epsilon \to 0.$$

If $r = +\infty$, the uniform control of $b^{\epsilon}_{sp}(s,\cdot) \mid_{B^{\beta}_{p,q}}$ readily yields

$$\mid b^{\epsilon}_{sp} - b \mid_{L^\infty([t,T],B^{\beta}_{p,q})} \to 0 \quad \epsilon \to 0.$$

If now $r < +\infty$, since from the previous arguments and from (Y) and (E.2),

$$\mid b^{\epsilon}_{sp}(s,\cdot) \mid_{B^{\beta}_{p,q}} \leq \mid b^{\epsilon}_{sp}(s,\cdot) \mid_{B^{\beta}_{p,q}} + \mid b(s,\cdot) \mid_{B^{\beta}_{p,q}} \leq (1 + c\gamma) \mid b(s,\cdot) \mid_{B^{\beta}_{p,q}} \leq (1 + c\gamma) \mid b(s,\cdot) \mid_{B^{\beta}_{p,q}} \in L^r([t,T]),$$

we get from the bounded convergence theorem that

$$\int_t^T ds \mid b^{\epsilon}_{sp}(s,\cdot) - b(s,\cdot) \mid_{B^{\beta}_{p,q}} \to 0.$$

Introduce $b^t(s,\cdot) = (\hat{b}^{\epsilon}_{sp}(\cdot,\cdot) \ast \eta_{\epsilon})(s)$ for a mollifier $\eta_{\epsilon}(\cdot) = \epsilon^{-1}\eta(\cdot/\epsilon)$ for some smooth compactly supported $\eta$, where $\ast$ stands for the convolution in the time argument. Considering this additional convolution in time yields the statement. The uniform control of $\mid b^t \mid_{L^r(B^{\beta}_{p,q})}$ is then clear.

B. Proof of Lemma 3.

Given $s \in (t,T]$ and $f$ a bounded and smooth function on $\mathbb{R}^d$, with bounded derivatives, the function $\phi(v,\cdot) := \rho^{s-v} \ast f(x)$ is itself a smooth solution of the backward equation:

$$\begin{cases}
\partial_t \phi(v,x) + L_t^x(\phi)(v,x) = 0 \quad &\text{in } [t,s) \times \mathbb{R}^d, \\
\phi(s,\cdot) = f(\cdot).
\end{cases}\quad \text{(B.1)}$$

Itô’s formula applied to $\phi(v, X^\epsilon) \overline{X} t^\mu du$ over the interval $[t,s]$ yields, in view of (B.1),

$$f(X^\epsilon) = \phi(t,\xi) + \int_t^s B^\epsilon_{\rho_{\delta,\mu}}(v,X^\epsilon) \cdot \nabla \phi(v,X^\epsilon) dv + M^\epsilon$$
where
\[
M_s^{\varepsilon,t,\mu} = \begin{cases} 
\int_t^s \nabla \phi(v, X_v^{\varepsilon,t,\mu}) \cdot dW_v, & \text{if } \alpha = 2, \\
\int_t^s \int_{[0]} [\phi(v, X_v^{\varepsilon,t,\mu} + x) - \phi(v, X_v^{\varepsilon,t,\mu})] \tilde{N}(dv, dx), & \text{if } \alpha \in (1,2),
\end{cases}
\]
denoting by \( W \), the standard \( d \)-dimensional Brownian motion and by \( \tilde{N} \), the compensated Poisson measure.

Averaging the above expression further yields
\[
\int dx \, f(x) \rho_{t,\mu}^{\varepsilon}(s,x) = \int p_{s-t}^{\varepsilon} \ast f(y) \, \mu(dy) + \int_t^s dv \int_{\mathbb{R}^d} \{ B_{\rho_{t,\varepsilon}}^\varepsilon(v,y) \rho_{t,\mu}^\varepsilon(v,y) \} \cdot \nabla p_{s-v}^{\varepsilon} \ast f(y) \tag{B.2}
\]
By Fubini’s theorem, the convolution with \( p_{s-t}^{\varepsilon} \) can be shifted to \( \mu \) and \( \int p_{s-t}^{\varepsilon} \ast f(y) \, \mu(dy) \) rewrites as \( \int dx \, f(x) \, p_{s-t}^{\varepsilon} \ast \mu(x) \). In the same way, observe that, since \( |\rho_{t,\mu}^\varepsilon(v,\cdot)|_{L^1} = 1 \) for all \( v > t \),
\[
\int_t^s dv \int dx \, f(x) |\nabla p_{s-v}^{\varepsilon}(y-x)| |B_{\rho_{t,\varepsilon}}^\varepsilon(v,y)||\rho_{t,\mu}^\varepsilon(v,y)| \leq |f|_{L^\infty} \int_t^s dv |\nabla p_{s-v}^{\varepsilon}|_{L^1} |B_{\rho_{t,\varepsilon}}^\varepsilon(v,\cdot)|_{L^\infty} = |f|_{L^\infty} \int_t^s dv |\nabla p_{s-v}^{\varepsilon}|_{L^1} |B_{\rho_{t,\varepsilon}}^\varepsilon(v,\cdot)|_{L^\infty}.
\]
Using (Y) and again that \( |\rho_{t,\mu}^\varepsilon(v,\cdot)|_{L^1} = 1 \), it follows that for all \( v \),
\[
|B_{\rho_{t,\varepsilon}}^\varepsilon(v,\cdot)|_{L^\infty} = |b^\varepsilon(v,\cdot) \ast \rho_{t,\mu}^\varepsilon(v,\cdot)|_{L^\infty} \leq |b^\varepsilon|_{L^\infty(L^\infty)}.
\]
Therefore, applying the embedding \( |\nabla p_{s-v}^{\varepsilon}|_{L^1} \leq C |\nabla p_{s-v}^{\varepsilon}|_{L^1} \) (following (E3)) and next (HK) for \( \gamma = 0, \ell = 1 = m \),
\[
\int_t^s dv \int dy \int dx |f(x)| |\nabla p_{s-v}^{\varepsilon}(y-x)| |B_{\rho_{t,\varepsilon}}^\varepsilon(v,y)||\rho_{t,\mu}^\varepsilon(v,y)| \leq C |f|_{L^\infty} |b^\varepsilon|_{L^\infty(L^\infty)} \int_t^s \frac{dv}{(s-v)^{\frac{3}{2}}} < \infty,
\]
the finiteness being granted by the fact that \( \alpha > 1 \). Consequently, (B.2) rewrites as
\[
\int dx \, f(x) \rho_{t,\mu}^\varepsilon(s,x) = \int dx \, f(x) \left[ p_{s-t}^{\varepsilon} \ast \mu(x) - \int_t^s dv \left( \nabla p_{s-v}^{\varepsilon} \ast \left( B_{\rho_{t,\varepsilon}}^\varepsilon(v,x) \rho_{t,\mu}^\varepsilon(v,x) \right) \right) \right].
\]
By a density argument, we can extend the previous computations to the class of functions \( f \) that are only bounded measurable functions and we eventually deduce that, for all \( t \leq s \leq T \) and for a.e. \( x \) in \( \mathbb{R}^d \),
\[
\rho_{t,\mu}^\varepsilon(s,x) = p_{s-t}^{\varepsilon} \ast \mu(x) - \int_t^s dv \left( \nabla p_{s-v}^{\varepsilon} \ast \left( B_{\rho_{t,\varepsilon}}^\varepsilon(v,x) \rho_{t,\mu}^\varepsilon(v,x) \right) \right).
\]
By continuity of \( y \mapsto \rho_{t,\mu}^\varepsilon(s,y) \), the equality extends to all point \( y \) of \( \mathbb{R}^d \).

Acknowledgements. For the first and third authors this work has partially been supported by the Russian Science Foundation project (project N20-11-20119). The second author acknowledges the support of the Russian Excellence project *5-100*. This joint work and its companion [18] were both initiated in May 2021. The first author also thanks the Centre Henri Lebesgue ANR-11-LABX-0020-01 for creating an attractive mathematical environment.
