We study exclusive nonleptonic two-body $B_c \rightarrow \{D_{(s)}, \eta_c, B_{(s)}\} + F$ decays with $F$(pseudoscalar or vector meson) factored out in the QCD factorization approach. The nonleptonic decay amplitudes are related to the product of meson decay constants and the form factors for semileptonic $B_c$ decays. As inputs in obtaining the branching ratios for a large set of nonleptonic $B_c$ decays, we use the weak form factors for the semileptonic $B_c \rightarrow \{D_{(s)}, \eta_c, B_{(s)}\}$ decays in the whole kinematical region and the unmeasured meson decay constants obtained from our previous light-front quark model. We compare our results for the branching ratios with those of other theoretical studies.

I. INTRODUCTION

The discovery of the $B_c$ meson by the Collider Detector at Fermilab(CDF) Collaboration $^1$ in $p\bar{p}$ collisions at $\sqrt{s} = 1.8$ TeV and the subsequent measurement of its lifetime have provided a new window for the analysis of the heavy-quark dynamics and thus for an important test of quantum chromodynamics. Recently the CDF and D0 Collaborations announced some new measurements of the $B_c$ meson lifetime and mass $^2, ^3$, $\tau_{B_c} = 0.463 \pm 0.073$(stat) $\pm 0.036$(syst) ps $^2$, $M_{B_c} = 6275.6 \pm 2.9$(stat)$\pm 2.5$(syst) MeV $^2$, and 6300$\pm 14$(stat)$\pm 5$(syst) MeV $^3$. The LHC is expected to produce around $\sim 5 \times 10^{10} B_c$ events per year $^4, ^5$. This will provide more detailed information on the decay properties of the $B_c$ meson. Since the $B_c$ mesons carry flavor explicitly($b$ and $c$) and cannot annihilate into gluons, they are stable against strong and electromagnetic annihilation processes. The decays of the $B_c$ meson are therefore only via weak interactions, which can be divided into three classes at the quark level: (1) the $b \rightarrow q (q = c, u)$ transition with the $c$ quark being a spectator, (2) the $c \rightarrow q (q = s, d)$ transition with the $b$ quark being a spectator, and (3) the weak annihilation channels. Although the phase space of the $c \rightarrow s, d$ transitions is much smaller than the phase space of the $b \rightarrow c, u$ transitions, the Cabibbo-Kobayashi-Maskawa(CKM) matrix elements are greatly in favor of the $c$ quark decay, i.e.$|V_{ub}| << |V_{cs}|$. In fact, the $c$-quark decays provide about $\sim 70\%$ of the $B_c$ decay width while the $b$-quark decays and the weak annihilation yield about $20\%$ and $10\%$, respectively $^6$. This indicates that both $b$- and $c$-quark decay processes contribute to the $B_c$ decay width on a comparable footing.

Because the $b$ and $c$ quarks can decay individually and the $B_c$ meson has a sufficiently large mass, one can study a great variety of decay channels. There have been many theoretical efforts to calculate the semileptonic $5, ^6, ^7, ^8, ^9, ^{10}, ^{11}, ^{12}, ^{13}, ^{14}, ^{15}, ^{16}, ^{17}, ^{18}, ^{19}, ^{20}, ^{21}, ^{22}, ^{23}, ^{24}, ^{25}, ^{26}$ and non-leptonic $4, ^{14}, ^{15}, ^{16}, ^{17}, ^{18}, ^{19}, ^{20}, ^{21}, ^{22}, ^{23}, ^{24}, ^{25}, ^{26}, ^{27}, ^{28}, ^{29}, ^{30}, ^{31}, ^{32}, ^{33}, ^{34}, ^{35}, ^{36}, ^{37}, ^{38}, ^{39}, ^{40}, ^{41}, ^{42}$ decays of the $B_c$ meson. The semileptonic $B_c$ decays provide a good opportunity to measure not only the CKM elements such as $|V_{cb}|$, $|V_{ub}|$, $|V_{cs}|$ and $|V_{cd}|$ but also the weak form factors for the transitions of $B_c$ to bottom and charmed mesons. The nonleptonic $B_c$ decays, in which only hadrons appear in the final state, are strongly influenced by the confining color forces among the quarks. While in the semileptonic transitions the long-distance QCD effects are described by a few hadronic form factors parametrizing the hadronic matrix elements of quark currents, the nonleptonic processes are complicated by the phenomenon of the quark rearrangement due to the exchange of soft and hard gluons. The theoretical description of the nonleptonic decays involves the matrix elements of the local four-quark operators. Although the four-quark operators are more complicated than the current operators involved in the semileptonic decays, the nonleptonic decays of the heavy mesons are useful for exploring the most interesting aspect of the QCD, i.e. its nonperturbative long-range character.

In our recent paper $^{43}$, we analyzed the semileptonic $B_c$ decays such as $B_c \rightarrow \{D_{(s)}, \eta_c, B_{(s)}\}\ell \nu_\ell$ and $\eta_c \rightarrow B_s \ell \nu_\ell(\ell = e, \mu, \tau)$ using our light-front quark model(LFQM) based on the QCD-motivated effective LF Hamiltonian $^{44, 45, 46, 47, 48, 49}$. The weak form factors $f_{\pm}(q^2)$ for the semileptonic decays between two pseudoscalar mesons are obtained in the $q^+ = 0$ frame ($q^2 = -q_{11}^2 < 0$) and then analytically continued to the timelike region by changing $q_{11}^2$ to $-q^2$ in the form factor. The covariance (i.e., frame independence) of our model has been checked by performing the LF calculation in the $q^+ = 0$ frame in parallel with the manifestly covariant fermion field theory model in $(3 + 1)$ dimensions. We also found the zero-mode contribution to the form factor $f_{\pm}(q^2)$ and identified the zero-mode operator that is convoluted with the initial and final state LF wave functions.

In this paper, we extend our previous LFQM analysis of the semileptonic $B_c$ decays $^{43}$ to the nonleptonic two-body decays of $B_c$ mesons such as $B_c \rightarrow (D_{(s)}, \eta_c, B_{(s)})P$ and $B_c \rightarrow (D, \eta_c, B_{(s)})V$(here $P$ and $V$ denote pseudoscalar and vector mesons, respectively). The QCD factorization approach is widely used since it works reasonably well in heavy-quark physics $^{50, 51, 52, 53, 54, 55}$. The factorization approximates the complicated non-
leptonic decay amplitude into the product of the meson decay constant and the form factor. A justification of this assumption is usually based on the idea of color transparency \[56\]. We shall use the form factors for semileptonic \( B_c \rightarrow (D_s, \eta_c, B_s) \) decays as well as the meson decay constants obtained in our LFQM \[43, 45\] as input parameters for the nonleptonic \( B_c \) decays. As done by many others \[3, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14\], we consider only the contribution of current-current operators at the tree level and calculate the decay widths for various nonleptonic \( B_c \) decays. As far as the decay width is concerned, the contribution from the tree diagram is much larger than that from the penguin diagram. The penguin contribution may be important in evaluating the CP violation and looking for new physics beyond the standard model, which we do not consider in this work.

The paper is organized as follows. In Sec. II, we discuss the weak Hamiltonian responsible for the nonleptonic two-body decays of the \( B_c \) meson. In Sec. III, we present the input parameters such as the weak decay constants and the form factors obtained in our LFQM \[43, 45\] based on the QCD-motivated effective Hamiltonian \[41, 43\]. The mixing angles between \( \eta \) and \( \eta' \) mesons are also analyzed, both in octet-singlet and quark-flavor bases, to extract the decay constants relevant to \( \eta \) and \( \eta' \) mesons. Section IV is devoted to the numerical results. A summary and conclusions follow in Sec.V.

## II. NONLEPTONIC TWO-BODY DECAYS OF THE \( B_c \) MESON

The nonleptonic weak decays are described in the standard model by a single \( W \) boson exchange diagram at tree level. In the standard model, the nonleptonic \( B_c \) decays are described by the effective Hamiltonian, which was obtained by integrating out the heavy \( W \) boson and top quark. For the case of \( b \rightarrow c, u \) and \( c \rightarrow s, d \) transitions at the quark level, neglecting QCD penguin operators, one gets the following effective weak Hamiltonian:

\[
\mathcal{H}_{\text{eff}}^{b \rightarrow c(u)} = \frac{G_F}{\sqrt{2}} \left\{ V_{cb}(c_1(\mu)\mathcal{O}_{1}^{cb} + c_2(\mu)\mathcal{O}_{2}^{cb}) + V_{ub}(c_1(\mu)\mathcal{O}_{1}^{ub} + c_2(\mu)\mathcal{O}_{2}^{ub}) + \text{h.c.} \right\},
\]

(1)

and

\[
\mathcal{H}_{\text{eff}}^{c \rightarrow s(d)} = \frac{G_F}{\sqrt{2}} \left\{ V_{cd}(c_1(\mu)\mathcal{O}_{1}^{cd} + c_2(\mu)\mathcal{O}_{2}^{cd}) + V_{cs}(c_1(\mu)\mathcal{O}_{1}^{cs} + c_2(\mu)\mathcal{O}_{2}^{cs}) + \text{h.c.} \right\},
\]

(2)

where \( G_F \) is the Fermi coupling constant and \( V_{q_1q_2} \) are the corresponding CKM matrix elements. We use the central values of the CKM matrix elements quoted by the Particle Data Group(PDG) \[57\] that we summarize in Table I. The effective weak Hamiltonian consists of products of local four-quark operators \( \mathcal{O}_{1,2} \) renormalized at the scale \( \mu \), and scale-dependent Wilson coefficients \( c_{1,2}(\mu) \), which incorporate the short-distance effects arising from the renormalization of \( \mathcal{H}_{\text{eff}} \) from \( \mu = m_W \) to \( \mu = O(m_b) \). The local four-quark operators \( \mathcal{O}_1 \) and \( \mathcal{O}_2 \) due to \( b \) and \( c \) decays are given by

\[
\begin{align*}
\mathcal{O}_{1}^{cb} &= (\bar{q}b)_{V-A}(d'u)_{V-A} + (\bar{s}c)_{V-A}(q = c, u), \\
\mathcal{O}_{2}^{cb} &= (\bar{q}u)_{V-A}(d'b)_{V-A} + (\bar{c}b)_{V-A}(\bar{s'}b)_{V-A}(q = c, u), \\
\mathcal{O}_{1}^{cs} &= (\bar{e}q)_{V-A}(d'u)_{V-A}(q = s, d), \\
\mathcal{O}_{2}^{cs} &= (\bar{e}u)_{V-A}(d'q)_{V-A}(q = s, d),
\end{align*}
\]

(3)

where \( (\bar{q}q)_{V-A} = \bar{q}q(1 - \gamma_5)q \) and the rotated antiquark fields are given by

\[
\begin{align*}
\bar{d'} &= V_{ud}d + V_{us}s, \\
\bar{s'} &= V_{cd}d + V_{cs}s.
\end{align*}
\]

(4)

Without strong-interaction effects, one would have \( c_1 = 1 \) and \( c_2 = 0 \). However, this simple result is modified by gluon exchange: i.e., the original weak vertices get renormalized and the new types of interactions(such as the operators \( \mathcal{O}_3 \)) are induced \[51\]. In these decays, the final hadrons are produced in the form of pointlike color-singlet objects with a large relative momentum. Thus, the hadronization of the decay products occurs after they separate far away from each other. This provides the possibility to avoid the final state interaction. A more general treatment of factorization was presented in \[58, 59\].

For the operators \( \mathcal{O}_1 = (\bar{q}_1 q_2)_{V-A}(\bar{q}_1' q_2')_{V-A} \) and \( \mathcal{O}_2 = (\bar{q}_1 q_2)_{V-A}(\bar{q}_1' q_2')_{V-A} \), using the Fierz transformation under which \( V - A \) currents remain \( V - A \) currents, one gets the following equivalent forms

\[
c_1\mathcal{O}_1 + c_2\mathcal{O}_2 = a_1\tilde{\mathcal{O}}_1 + c_2\tilde{\mathcal{O}}_2 = a_2\mathcal{O}_2 + c_1\tilde{\mathcal{O}}_1,
\]

(5)

where

\[
\begin{align*}
\mathcal{O}_1 &= \mathcal{O}_1, \quad \mathcal{O}_2 = \mathcal{O}_2, \\
a1(\mu) &= c_1(\mu) + \frac{1}{N_c}c_2(\mu), \quad a2(\mu) = c_2(\mu) + \frac{1}{N_c}c_1(\mu),
\end{align*}
\]

(6)

and \( N_c \) is the number of colors. The terms \( \mathcal{O}_1 = (\bar{q}_1 T^a q_2)_{V-A}(\bar{q}_1' T^a q_2')_{V-A} \) and \( \mathcal{O}_2 = (\bar{q}_1 T^a q_2)_{V-A}(\bar{q}_1' T^a q_2')_{V-A} \) with SU(3) color generators \( T^a \) are the nonfactorizable color-octet current operators, which are neglected in the factorization assumption. A detailed analysis of \( 1/N_c \) corrections to the coefficients \( a_1, a_2 \) as well as the role of color-octet current operators in \( B \) decays can be found in \[51\].

In the factorization approach to nonleptonic meson decays, one can distinguish three classes of decays for which

---

**TABLE I: Values for CKM matrix elements used in this work.**

| \( V_{ud} \) | \( V_{us} \) | \( V_{cd} \) | \( V_{cs} \) | \( V_{cb} \) | \( V_{ub} \) |
|---|---|---|---|---|---|
| 0.974 | 0.2255 | -0.230 | 1.04 | 0.0412 | 0.00393 |
the amplitudes have the following general structure [50]:

\[
\begin{align*}
\text{(class I)} & : \frac{G_F}{\sqrt{2}} V_{CKM} a_1(\mu) \langle \mathcal{O}_1 \rangle_F, \\
\text{(class II)} & : \frac{G_F}{\sqrt{2}} V_{CKM} a_2(\mu) \langle \mathcal{O}_2 \rangle_F, \\
\text{(class III)} & : \frac{G_F}{\sqrt{2}} V_{CKM} [a_1(\mu) + x a_2(\mu)] \langle \mathcal{O}_1 \rangle_F,
\end{align*}
\]

where \( \langle \mathcal{O}_i \rangle_F \) represents the hadronic matrix element given as the products of matrix elements of quark currents and \( x \) is a nonperturbative factor equal to unity in the flavor symmetry limit [51]. The first (second) class is caused by a color-favored (color-suppressed) tree diagram and contains those decays in which only a charged (neutral) meson can be generated directly from a color-singlet current. The first and second class decay amplitudes are proportional to \( a_1 \) and \( a_2 \), respectively. The third class of transitions consists of those decays in which both \( a_1 \) and \( a_2 \) amplitudes interfere.

In this paper, we consider the following type of nonleptonic \( B_c \to F_1 + F_2 \) where \( F_1 \) is the pseudoscalar meson(\( \eta_c, D_s, B_s \)) and \( F_2 \) the meson(vector or pseudoscalar) being factored out. For instance, the factorized matrix element of \( B_c^+ \to F_1 F_2^+ \) with \( F_1 = \eta_c \) and \( F_2 = \pi \) is defined as

\[
X(B_c^+ F_1 F_2^+) \equiv \langle F_1 | (\bar{c} b)_{V-A} | B_c \rangle \langle F_2 | (\bar{d} u)_{V-A} | 0 \rangle.
\]

The matrix elements of the semileptonic \( B_c \to F_1 \) decays can be parametrized by two Lorentz-invariant form factors:

\[
\langle F_1 (P_2) | (\bar{q} q')_{V-A} | B_c (P_1) \rangle = f_+(q^2) P^\mu + f_-(q^2) q^\mu,
\]

where \( P = P_1 + P_2 \) and \( q = P_1 - P_2 \). The two form factors also satisfy the following relation:

\[
f_0(q^2) = f_+(q^2) + \frac{q^2}{M_F^2 - M_0^2} f_-(q^2).
\]

The decay constants \( f_P \) and \( f_V \) of pseudoscalar(\( P) \) and vector(\( V) \) mesons are defined by

\[
\langle P(p) | (\bar{q} q')_{V-A} | 0 \rangle = -i f_P p^\mu, \\
\langle V(p, h) | (\bar{q} q')_{V-A} | 0 \rangle = f_V M_V e^\mu(h),
\]

where \( \epsilon(h) \) is the polarization vector of the vector meson. In the above definitions for the decay constants, the experimental values of pion and rho meson decay constants are \( f_\rho \approx 131 \text{ MeV} \) from \( \pi \to \mu \nu \) and \( f_\rho \approx 220 \text{ MeV} \) from \( \rho \to e^+ e^- \).

Using Eqs. (11) and (13), we obtain the following expressions for the factorized matrix elements:

\[
X(B_c^+ F_1 F_2^+) = -i f_P (M_{B_c}^2 - M_{F_1}^2) f_{0-B_c}^{-F_1} (M_{F_2}^2),
\]

when \( F_2 \) is a pseudoscalar meson, and

\[
X(B_c^+ F_1 V^+) = 2 f_V M_V (\epsilon \cdot P_{B_c}) f_{+B_c}^{-F_1} (M_{V}^2),
\]

when \( F_2 \) is a vector meson. For the latter case, only longitudinally polarized vector mesons are produced in the rest frame of the decaying \( B_c \) meson, i.e.,

\[
\epsilon \cdot P_{B_c} = \frac{M_{B_c}}{M_V} p_c,
\]

where

\[
p_c = \sqrt{[M_{B_c}^2 - (M_1 + M_2)^2][M_{B_c}^2 - (M_1 - M_2)^2]} / 2 M_{B_c},
\]

is the center of mass momentum of the final state meson(\( F_1 \) with \( M_1 \) or \( F_2 \) with \( M_2 \)).

The decay rate for \( B_c \to F_1 + F_2 \) in the rest frame of the \( B_c \) meson is given by

\[
\Gamma(B_c \to F_1 F_2) = \frac{p_c}{8 \pi M_{B_c}^3} |(F_1 F_2 | \mathcal{H}_{\text{eff}} | B_c^+)^2|.
\]

In Fig. 1 we show the example of quark diagrams for the nonleptonic \( B_c \to BK \) decays: (a) color-favored(class I) \( B_c^+ \to B^0 K^+ \) and (b) color-suppressed(class II) \( B_c^+ \to B^+ K^0 \) decays. We also show in Fig. 2 the example of quark diagrams for the class III transitions such as \( B_c \to D^+ D^0 \). In the factorization approximation, these nonleptonic decay amplitudes can be expressed as the product of one-particle matrix elements.

### A. Class I decay modes

(1) For the \( b \to (u, c)(q_1 \bar{q}_2) \) process,

\[
\langle D^0 M^+ | \mathcal{H}_{\text{eff}} | B_c^+ \rangle_1 = \frac{G_F}{\sqrt{2}} V_{ub} V_{q_1 q_2}^* q_1 X(B_c^+ D^0, M^+),
\]

and

\[
\langle \eta_c M^+ | \mathcal{H}_{\text{eff}} | B_c^+ \rangle_1 = \frac{G_F}{\sqrt{2}} V_{ub} V_{q_1 q_2}^* q_1 X(B_c^+ \eta_c, M^+),
\]
FIG. 2: Quark diagrams for the class III nonleptonic $B_c \to D^+ D^0$ decay, which consist of both color-favored (a) and color-suppressed (b) decays.

(2) For the $c \to (d, s)(q_1 \bar{q}_2)$ process,

$$\langle B^0 M^+ | \mathcal{H}_{\text{eff}} | B_c^+ \rangle = \frac{G_F}{\sqrt{2}} V_{cq} V_{\bar{q}1q_2}^* a_1 X(b^+_c b^0, M^+), \quad (21)$$

and

$$\langle B^0 M^+ | \mathcal{H}_{\text{eff}} | B_c^+ \rangle = \frac{G_F}{\sqrt{2}} V_{cs} V_{\bar{q}1q_2}^* a_1 X(b^+_c b^0, M^+), \quad (22)$$

where $M = \pi, K, \rho, K^*$ and $V_{q_1q_2} = V_{ud} \text{ or } V_{us}$ depending on whether $M = (\pi, \rho)$ or $(K, K^*)$.

B. Class II decay modes

(1) For the $b \to (d, s)(q_1 \bar{q}_2)$ process,

$$\langle D^+ M^0 | \mathcal{H}_{\text{eff}} | B_c^+ \rangle = \frac{G_F}{\sqrt{2}} V_{qb} V_{q_1q_2}^* a_2 X(b^+_c b^+, M^0), \quad (23)$$

and

$$\langle D^+ M^0 | \mathcal{H}_{\text{eff}} | B_c^+ \rangle = \frac{G_F}{\sqrt{2}} V_{qb} V_{q_1q_2}^* a_2 X(b^+_c b^+, M^0), \quad (24)$$

(2) For the $c \to u(q_1 \bar{q}_2)$ process,

$$\langle B^+ M^0 | \mathcal{H}_{\text{eff}} | B_c^+ \rangle = \frac{G_F}{\sqrt{2}} V_{cq} V_{q_1q_2}^* a_2 X(b^+_c b^+, M^0), \quad (25)$$

and

$$\langle B^+ M^0 | \mathcal{H}_{\text{eff}} | B_c^+ \rangle = \frac{G_F}{\sqrt{2}} V_{cq} V_{q_1q_2}^* a_2 X(b^+_c b^+, M^0), \quad (26)$$

where $M = (\pi, \eta, \rho, \omega, D^{(*)})$ for $c \to (d, s)$ induced decays and $M = (\pi, \rho, \omega, K^0, K, K^*, \bar{K})$ for $c \to u$ induced decays, respectively. As in the case of color-favored class I decay modes, the factorized matrix elements for color-suppressed class II decay modes can be obtained from Eqs. (11) and (12) except that the decay constants for the neutral $\pi^0, \rho^0$, and $\omega$ mesons are replaced by $f_{F(V)}/\sqrt{2}$.

C. Class III decay modes

For the class III $B_c^+ \to D^+_q M^0(q = d, s)$ transitions, the decay amplitude is given by

$$\langle D^+_q M^0 | \mathcal{H}_{\text{eff}} | B_c^+ \rangle = \frac{G_F}{\sqrt{2}} V_{cq} V_{\bar{q}1q_2}^* [a_1 X(b^+_c M^0, D^+_q) + a_2 X(b^+_c D^+_q, M^0)], \quad (27)$$

where $V_F = V_{cb}$ for $M = \eta_c$ and $V_{ub}$ for $M = D$. The expressions for the factorized matrix elements can be obtained from Eqs. (11) and (15).

III. INPUT PARAMETERS

In this section we shall briefly discuss and summarize all of the input parameters, such as the model parameters, decay constants, and form factors for semileptonic $B_c \to (D_{(s)}, \eta_c, B_{(s)})$ decays, which are relevant to the present work.

A. Brief review of LFQM

The key idea in our LFQM \[44, 45\] for the ground state mesons is to treat the radial wave function as a trial function for the variational principle to the QCD-motivated effective Hamiltonian saturating the Fock state expansion by the constituent quark and antiquark. The QCD-motivated effective Hamiltonian for a description of the ground state meson mass spectra is given by

$$H_{qq} = H_0 + V_{qq} = \sqrt{m_q^2 + \vec{k}^2} + \sqrt{m_q^2 + \vec{k}^2} + V_{qq}, \quad (28)$$

where

$$V_{qq} = V_0 + V_{\text{hyp}} = a + b \eta^2 + \frac{4\alpha_s}{3\pi} + \frac{2S_2 \cdot S_1}{3 m_q \eta} \nabla V_{\text{coul}}. \quad (29)$$

In this work, we use two interaction potentials: (1) the Coulomb plus linear confining (i.e. $n = 1$) potential and (2) the Coulomb plus harmonic oscillator (HO) (i.e. $n = 2$) potential, together with the hyperfine interaction $\langle S_q \cdot S_\bar{q} \rangle = 1/4(-3/4)$ for the vector (pseudoscalar) meson, which enables us to analyze the meson mass spectra and various wave-function-related observables, such as decay constants, electromagnetic form factors of mesons in a spacelike region, and the weak form factors for the exclusive semileptonic and rare decays of pseudoscalar mesons in the timelike region \[44, 45, 46, 47, 48, 49\].

The momentum-space light-front wave function of the ground state pseudoscalar and vector mesons is given by

$$\Psi(x_i, k_{i\perp}, \lambda_i) = R_{\lambda_i\lambda_1}(x_i, k_{i\perp}) \phi(x_i, k_{i\perp}),$$

where $\phi(x_i, k_{i\perp})$ is the radial wave function and $R_{\lambda_1\lambda_2}$ is the covariant spin-orbit wave function. The model wave function is represented by the Lorentz-invariant variables, $x_i = p_i^+ / P^+$, $k_{i\perp} = p_{i\perp} - x_i P_{\perp}$ and $\lambda_i$, where
\( P^\mu = (P^+, P^-, \mathbf{p}_\perp) = (P^0 + P^3, (M^2 + \mathbf{p}_\perp^2)/P^+, \mathbf{p}_\perp) \) is the momentum of the meson \( M \), and \( p_i \) and \( \lambda_i \) are the momenta and the helicities of constituent quarks, respectively.

The covariant forms of the spin-orbit wave functions for pseudoscalar and vector mesons are given by

\[
\mathcal{R}_{\lambda_1 \lambda_2}^{00} = \frac{-\bar{u}_{\lambda_2}(p_1) \gamma_5 v_{\lambda_2}(p_2)}{\sqrt{2}M_0},
\]

\[
\mathcal{R}_{\lambda_1 \lambda_2}^{1J} = \frac{-\bar{u}_{\lambda_2}(p_1) \left[ \Phi(J_\perp) - \frac{e^\alpha(p_1-p_2)}{M_0+m_1+m_2} \right] v_{\lambda_2}(p_2)}{\sqrt{2}M_0},
\]

where \( M_0 = \sqrt{M_0^2 - (m_1 - m_2)^2} \), \( M_0^2 = \sum_{i=1}^2 (k_{i\perp}^2 + m_i^2)/x_i \) is the boost invariant meson mass square obtained from the free energies of the constituents in mesons, and \( e^\alpha(J_\perp) \) is the polarization vector of the vector meson \( P \). For the radial wave function \( \phi \), we use the same Gaussian wave function for both pseudoscalar and vector mesons:

\[
\phi(x_i, k_{\perp}) = \frac{4\pi^{3/4}}{\beta^{3/4}} \sqrt{\frac{\partial k_{\perp}}{\partial x}} \exp(-k_{\perp}^2/2\beta^2),
\]

where \( \beta \) is the variational parameter and \( \sqrt{\partial k_{\perp}/\partial x} \) is the Jacobian of the variable transformation \( \{x, k_{\perp}\} \rightarrow \{\tilde{k}_{\perp}, \tilde{k}_z\} \).

We apply our variational principle to the QCD-motivated effective Hamiltonian first to evaluate the expectation value of the central Hamiltonian \( H_0 + V_0 \), i.e., \( \langle \phi | (H_0 + V_0) | \phi \rangle \), with a trial function \( \phi(x_i, k_{\perp}) \) that depends on the variational parameter \( \beta \). Once the model parameters are fixed by minimizing the expectation value \( \langle \phi | (H_0 + V_0) | \phi \rangle \), the mass eigenvalue of each meson is obtained as \( M_{q\bar{q}} = \langle \phi | (H_0 + V_0) | \phi \rangle \). Minimizing energies with respect to \( \beta \) and searching for a fit to the observed ground state meson spectra, our central potential \( V_0 \) obtained from our optimized potential parameters \( a = -0.72 \text{ GeV}, b = 0.18 \text{ GeV}^2 \), and \( \alpha_s = 0.31 \) \( \| \) for the Coulomb plus linear potential was found to be quite comparable with the quark potential model suggested by Scora and Isgur \( \| \) for the Coulomb plus linear potential was found to be quite comparable with the quark potential model suggested by Scora and Isgur \( \| \) for the Coulomb plus linear potential was found to be quite comparable with the quark potential model suggested by Scora and Isgur [41] for the Coulomb plus linear potential was found to be quite comparable with the quark potential model suggested by Scora and Isgur [41] for the Coulomb plus linear potential was found to be quite comparable with the quark potential model suggested by Scora and Isgur [41].

\[
f_+(q^2) = \int_0^1 dx \int \frac{d^2k_{\perp}}{16\pi^3} \frac{\phi_1(x, k_{\perp}) \phi'_2(x, k'_{\perp})}{\sqrt{A_{\perp}^2 + k_{\perp}^2} \sqrt{A_{\perp}^2 + k'_{\perp}^2}} \left( A_1 A_2 + k_{\perp} \cdot k'_{\perp} \right),
\]

\[
f_-(q^2) = \int_0^1 \left( 1 - x \right) dx \int \frac{d^2k_{\perp}}{16\pi^3} \frac{\phi_1(x, k_{\perp}) \phi'_2(x, k'_{\perp})}{\sqrt{A_{\perp}^2 + k_{\perp}^2} \sqrt{A_{\perp}^2 + k'_{\perp}^2}} \left\{ -x(1-x)M_1^2 - k_{\perp}^2 - m_1m_\bar{q} + (m_2 - m_\bar{q})A_1 \\
+2 \frac{q \cdot P}{q^2} \left[ k_{\perp} \cdot (k_{\perp} + q/2) \right] + 2 \left( \frac{k_{\perp} \cdot q_{\perp}}{q^2} \right)^2 + \frac{k_{\perp} \cdot q_{\perp}}{q^2} \frac{M_2^2 - (1-x)(q^2 + q \cdot P) + 2xM_0^2}{q^2} \right\},
\]

where \( b = 0.18 \text{ GeV}^2 \), and \( \alpha_s = 0.3 \sim 0.6 \) for the Coulomb plus linear confining potential. A more detailed procedure for determining the model parameters of light- and heavy-quark sectors can be found in our previous works [41, 42].

Our model parameters \( (m_q, \beta_{q\bar{q}}) \) obtained from the linear and HO potential models are summarized in Table II. The predictions of the ground state meson mass spectra including bottom-charmed mesons can be found in our recent work, Ref. [42].

**B. Form factors for semileptonic \( B_c \to P \) decays**

For the nonleptonic two-body \( B_c \) decays, we use the \( q^2 \) dependent form factors \( f_+(q^2) \) and \( f_0(q^2) \) for the \( B_c \to (D, D_s, \eta_c, B, B_s) \) decays as input parameters.

Within the framework of LF quantization, while the form factor \( f_+(q^2) \) can be obtained only from the valence contribution in the \( q^+ = 0 \) frame with the “+” component of the currents without encountering the zero-mode contribution [62], the form factor \( f_-(q^2) \) [or equivalently \( f_0(q^2) \)] receives the higher Fock state contribution (i.e., the zero-mode in the \( q^+ = 0 \) frame or the nonvalence contribution in the \( q^+ > 0 \) frame). In order to calculate \( f_-(q^2) \), we developed in [40, 47] an effective treatment of handling the higher Fock state (or nonvalence) contribution to \( f_-(q^2) \) in the purely longitudinal \( q^+ > 0 \) frame (i.e., \( q^2 = q^+ q^- > 0 \)) based on the Bethe-Salpeter(BS) formalism. In our recent LFQM analysis [42] of the semileptonic \( B_c \to (D, \eta_c, B, B_s)\ell\nu_\ell \) decays, we utilized our effective method [40] to express the zero-mode contribution as a convolution of zero-mode operator with the initial and final state LF wave functions. In this way, we obtained the form factor \( f_-(q^2) \) in the \( q^+ = 0 \) frame using the perpendicular components of the currents and discussed the LF covariance of \( f_-(q^2) \) in the valence region by analyzing the covariant BS model and the LF covariance analysis described by Jaus [63].

The LF covariant form factors \( f_+(q^2) \) and \( f_-(q^2) \) for \( B_c(q\bar{q}) \to P(q\bar{q}) \) transitions obtained from the \( q^+ = 0 \) frame are given by (see [43] for more detailed derivations).
where \( k' = k + (1 - x)q \), \( A_i = (1 - x)m_i + xm_{\bar{q}} \) \((i = 1, 2)\), and \( q \cdot P = M_1^2 - M_2^2 \) with \( M_1 \) and \( M_2 \) being the physical masses of the initial and final state mesons, respectively. We should note that the LF covariant form factor \( f'(q^2) \) in Eq. (32) is the sum of the valence contribution \( f^{\text{val}}_0(q^2) \) and the zero-mode contribution \( f^{\text{ZM}}_0(q^2) \).

For the analysis of the nonleptonic \( B_c \rightarrow D_F \) decays where \( F \) is the vector or pseudoscalar meson being factored out, we show in Fig. 3 the \( q^2 \)-dependence of the weak form factors \( f_+(q^2) \) (solid line) and \( f_0(q^2) \) (dashed line) for the \( B_c \rightarrow D_s \) transition obtained from the linear (upper panel) and HO (lower panel) potential parameters. The circles represent the valence contribution \( f_0^{\text{val}}(q^2) \) to \( f_0(q^2) \). That is, the difference between \( f_0(q^2) \) and \( f_0^{\text{val}}(q^2) \) represents the zero-mode contribution to \( f_0(q^2) \). We obtain \( f_+(0) = f_0(0) = 0.120 \) [0.126] at \( q^2 = 0 \) for the linear [HO] potential model. The form factors at the zero-recoil point (i.e., \( q^2 = q^2_{\text{max}} \)) are obtained as \( f_+(q^2_{\text{max}}) = 0.992 \) [0.868] and \( f_0(q^2_{\text{max}}) = 0.475 \) [0.493] for the linear [HO] potential model. On the other hand, the valence contribution to \( f_0(q^2) \) at the zero-recoil point is obtained as \( f_0^{\text{val}}(q^2_{\text{max}}) = 0.442 \) [0.443] for the linear [HO] potential model.

In Table III, we show the decay form factors \( f_+(0) = f_0(0) \) at \( q^2 = 0 \) for the semileptonic \( B_c \rightarrow (D, \eta_c, B, B_s) \) decays obtained from [43] and the rare \( B_c \rightarrow D_s \) decay obtained in the present work (i.e., Fig. 3) and compare them to other theoretical model predictions.

### C. Weak decay constants of \( \eta \) and \( \eta' \)

In this work, we shall also consider the nonleptonic decays of \( B_c \) mesons to isoscalar states such as \( \omega \) and \( (\eta, \eta') \). Isoscalar states with the same \( J^{PC} \) will mix, but mixing between the two light-quark isoscalar mesons, and the much heavier charmonium or bottomonium states is generally assumed to be negligible. Since the vector mixing angle is known to be very close to ideal mixing, we assume ideal mixing between \( \omega \) and \( \phi \) mesons, i.e., \( \omega = (u\bar{u} + d\bar{d})/\sqrt{2} \) and \( \phi = s\bar{s} \). However, the octet-singlet mixing angle \( \theta \) of \( \eta \) and \( \eta' \) is known to be in the range of \(-10^\circ\) to \(-23^\circ\). The physical \( \eta \) and \( \eta' \) are the mixtures of the flavor \( SU(3) \) octet \( \eta_8 \) and singlet \( \eta_0 \) states:

\[
\begin{pmatrix} \eta \\ \eta' \end{pmatrix} = U(\theta) \begin{pmatrix} \eta_8 \\ \eta_0 \end{pmatrix},
\]

where

\[
U(\theta) = \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix},
\]

and \( \eta_8 = (u\bar{u} + d\bar{d} - 2s\bar{s})/\sqrt{6} \) and \( \eta_0 = (u\bar{u} + d\bar{d} + s\bar{s})/\sqrt{3} \). Analogously, in terms of the quark-flavor basis \( \eta_q = (u\bar{u} + d\bar{d} + s\bar{s})/\sqrt{3} \).
where $\Psi_3$ denote LF wave functions of the corresponding parton states. Only in the SU$_f$(3) symmetry limit, i.e., $\Psi_q = \Psi_s$, would one find pure octet and singlet states in Eq. (36). Although it was frequently assumed that the decay constants follow the same pattern of state mixing, the mixing properties of the decay constants will generally be different from the mixing properties of the meson state since the decay constants only probe the short-distance properties of the valence Fock states while the state mixing refers to the mixing of the overall wave function [64].

Using the decay constants of Eq. (34) defined in the quark-flavor basis, the two basic decay constants $f_q$ and $f_s$ arising from $\eta_q$ and $\eta_s$ are obtained as

$$f_{q(s)} = 2\sqrt{6} \int_0^1 dx \int \frac{d^3k}{16\pi^3} \Psi_{q(s)},$$

and simply follow the pattern of state mixing due to the Okubo-Zweig-Iizuka(OZI) rule [62], i.e.,

$$\begin{pmatrix} f_q & f_q^* \\ f_s & f_s^* \end{pmatrix} = U(\phi) \begin{pmatrix} f_q \ 0 \\ 0 \ f_s \end{pmatrix} \tag{37}$$

The OZI rule implies that the difference between the two mixing angles $\phi_q$ and $\phi_s$ vanishes (i.e., $\phi_s = \phi_q = \phi$ in Eq. (35) to leading order in the $1/N_c$ expansion. On the other hand, the decay constants in the octet-singlet basis are parametrized as [64]

$$\begin{pmatrix} f_8 & f_8^* \\ f_0 & f_0^* \end{pmatrix} = \begin{pmatrix} \cos \theta_8 & -\sin \theta_0 \\ \sin \theta_8 & \cos \theta_0 \end{pmatrix} \begin{pmatrix} f_8 \ 0 \\ 0 \ f_0 \end{pmatrix}, \tag{38}$$

where $\theta_8$ and $\theta_0$ turn out to differ considerably and become equal only in the SU$_f$(3) symmetry limit.

By using the correlation between the quark-flavor mixing scheme and the octet-singlet scheme [64, 65], one obtains

$$f_8 = \sqrt{\frac{f_q^2 + f_s^2}{3}}, \quad \theta_8 = \phi - \arctan(\sqrt{2}f_s/f_q),$$

$$f_0 = \sqrt{\frac{f_q^2 + f_s^2}{3}}, \quad \theta_0 = \phi - \arctan(\sqrt{2}f_q/f_s). \tag{40}$$

In our previous work [44], we obtained the $\eta - \eta'$ mixing angle $\phi \simeq -19^\circ$ for both linear and HO potential models by fitting the physical masses of $\eta$ and $\eta'$. This corresponds to the mixing angle $\phi = 35.7^\circ$ in the quark-flavor basis. We applied this mixing angle to predict the decay widths for $\eta(\eta') \to \gamma \gamma$ using the axial anomaly plus partial conservation of the axial vector current (PCAC) relations [67] and obtained $f_8/f_\pi = 1.32 (1.25)$ and $f_0/f_\pi = 1.16 (1.13)$ for the linear (HO) potential model [44]. From the decay constants of octet and singlet mesons together with Eq. (40), we now obtain the four parameters $(f_q, f_s, \theta_8, \theta_0)$ as follows: $f_q/f_\pi = 0.97 (1.00)$, $f_s/f_\pi = 1.46 (1.36)$, $\theta_8 = -29.2^\circ (26.8^\circ)$, and $\theta_0 = -7.3^\circ (10.6^\circ)$ for the linear (HO) potential model, respectively. Given this background, we finally obtain the decay constants related to the $\eta$ and $\eta'$ mesons as follows

$$f_8^\eta = 103.2 (106.4) \text{ MeV}, \quad f_0^\eta = -116.6 (-104.0) \text{ MeV},$$

$$f_8^\eta' = 74.2 (76.4) \text{ MeV}, \quad f_0^\eta' = 155.3 (144.7) \text{ MeV}. \tag{41}$$

Our results for the mixing parameters of $\eta$ and $\eta'$ are consistent with those obtained from Feldmann et al. [64], namely, $f_8/f_\pi = 1.26$, $f_0/f_\pi = 1.17$, $f_q/f_\pi = 1.07 \pm 0.02$, $f_s/f_\pi = 1.34 \pm 0.06$, $\phi = (39.3^\circ \pm 1.0^\circ)$, $\theta_8 = -21.2^\circ$, $\theta_0 = -9.2^\circ$, $f_q^\eta = 108.5 \pm 2.0 \text{ MeV}$, $f_s^\eta = -111.2 \pm 5.0 \text{ MeV}$, $f_q^\eta' = 88.8 \pm 1.7 \text{ MeV}$, and $f_s^\eta' = 135.8 \pm 6.1 \text{ MeV}$.

For the measured values of meson decay constants, we use the central values extracted from the experimental measurements [57, 68, 69]. However, for the unmeasured

| Table III: Form factors $f_4(0) = f_0(0)$ at $q^2 = 0$ for $B_c \to (D_{(s)}, \eta_c, B, B_s)$ transitions. |

decay constants, we use the average values obtained from our linear and HO model predictions in \[48\] in addition to the present work. The values for the decay constants used in this work are compiled in Table \[IV\]. Since the decay constant \(f_\eta\) extracted from CLEO Collaboration \[71\] has a large error bar, i.e., \(f_\eta^{\text{CLEO}} = 335 \pm 75 \text{ MeV}\), we instead take the average value \(f_\eta = 340 \text{ MeV}\) of our LFQM predictions \[\mathbb{R}\], i.e., \(f_\eta^{\text{lin}} = 326 \text{ MeV}\) and \(f_\eta^{\text{HO}} = 354 \text{ MeV}\).

### IV. NUMERICAL RESULTS

In our numerical calculations of exclusive \(B_c\) decays, we use two sets of model parameters \((m, \beta)\) for the linear and HO confining potentials given in Table \[II\] to compute the weak form factors for semileptonic \(B_c \to (D_{(s)}, \eta_c, B_{(s)})\) decays and the unmeasured decay constants as given in Tables \[III\] and \[IV\] respectively. Using them together with the CKM matrix elements given by Table \[I\] we finally predict the branching ratios which are given in Tables \[V\] and \[VI\]. Although we show the form factors in Table \[III\] only at a maximum recoil point \(q^2 = 0\), we use the form factor at \(q^2 = M_F^2\) obtained from \[13\] for the corresponding nonleptonic \(B_c \to (D_{(s)}, \eta_c, B_{(s)})M_F\) decays.

In Table \[V\] we show the nonleptonic decay widths of the \(B_c\) meson for a general value of the Wilson coefficients \(a_1\) and \(a_2\), whereas in Table \[VI\] we give the corresponding branching ratios (in \%) at the fixed choice of Wilson coefficients \[23\]: \(a_1' = 1.20\) (1.14) and \(a_2' = -0.317\) (−0.20) relevant for the nonleptonic decays of the \(c\) (\(\bar{b}\)) quark. For the lifetime of the \(B_c\), we take the central value \(\tau(B_c) = 0.46\) ps (i.e. \(\Gamma_{\text{tot}} = 1.43 \times 10^{-12} \text{ GeV}\)) presented in PDG \[57\]. Our branching ratios for both \(b\) and \(c\) induced decays listed in Table \[VI\] are generally close to the other quark model results \[7,8,9,14,26\] but differ substantially from the ones obtained by Refs. \[5,10,40\].

The relative size of the branching ratios for various decay modes may be estimated from power counting of the Wilson coefficients \(a_1\) and \(a_2\) with respect to the small parameter of the Cabibbo angle \(\lambda = \sin \theta_C\) in the Wolfenstein parametrization \[71\], e.g. the CKM matrix elements can be expanded in terms of \(\lambda\) as \(V_{ud} \sim 1\), \(V_{us} \sim \lambda\), \(V_{cb} \sim \lambda^3\), \(V_{cd} \sim -\lambda\), \(V_{cs} \sim 1\), and \(V_{ub} \sim \lambda^2\). From Tables \[V\] and \[VI\] we make the following observations:

1. The class I decay modes determined by the Wilson coefficient \(a_1\) have comparatively large branching ratios. The CKM favored decays such as \(B_c^+ \to B_{s0}^0 (\pi^+, \rho^+)\) decays with the CKM factor \(V_{cs}V_{ud}^* \sim \lambda^1\) have branching ratios of the order of \(10^{-2}\) (e.g. \(2\% \sim 4\%\) in our model predictions), which are the most promising class I decay modes shown in Table \[V\] and \[VI\]. The CKM-suppressed \(c\) decays such as \(B_c^+ \to B_{s0}^0 K^+\) with \(V_{cs}V_{us}^* \sim \lambda^1\) and \(B_c^+ \to B_{s0}^+ (\pi^+, \rho^+)\) with \(V_{cd}V_{ud}^* \sim \lambda^1\), having branching ratios of the order of \(10^{-3}\) and should still be accessible at high luminosity hadron colliders. However, the branching ratios of the \(b \to u\) induced decay modes are too small \(\mathcal{O}(10^{-8} - 10^{-6})\) to be measured experimentally.

2. The branching ratios for the class II decay modes determined by \(a_2\) are relatively smaller than those for the class I decay modes. However, the \(B_c^+ \to B_{s0}^0 (K^0, \bar{K}^{*0})\) decays with \(V_{cs}V_{ud}^* \sim \lambda^0\) have branching ratios of the order of \(10^{-3}\) and these modes should be accessible experimentally. Of interest is the abnormally small branching ratio of \(B_c^+ \to B_{s0}^+ \eta'\) compared to that of \(B_c^+ \to B_{s0}^+ \eta\). As stated in \[40\], the reason for such a small branching ratio is not only because the available physical phase space is too small but also because there are large destructive interferences between \(\eta'_c\) and \(\eta_c\) due to the serious cancellation between the CKM factors \(V_{cs}V_{us}^*\) (and \(V_{cs}V_{us}^*\))

3. The class III decay modes involve the Pauli interference. Taking into account the negative value of \(a_2\) with respect to \(a_1\), one can see that the class III decay modes shown in Table \[VI\] should be suppressed in comparison with the cases in which the interference is switched off. In order to test the effects of the interference, one may put the widths in the form of \(\Gamma = \Gamma_0 + \Delta \Gamma\), where \(\Gamma_0 = x_1a_1^2 + x_2a_2^2\) and \(\Delta \Gamma = x_3a_1a_2\), and then compute the \(\Delta \Gamma/\Gamma_0\) (in \%) as done in \[23\]. Our absolute values of \(\Delta \Gamma/\Gamma_0\) obtained from the linear (HO) model are 34.0 (34.0\%) for \(B_c^+ \to D^{*0}D^0\), 37.3 (42.4\%) for \(B_c^+ \to D^{*+}D^0\), 18.4 (15.1\%) for \(B_c^+ \to \eta D^{*+}\), and 20.2 (18.9\%) for \(B_c^+ \to \eta D^+, \) respectively. This indicates that the interference is the most significantly involved in the \(B_c^+ \to D^{*0}D^0\) decay compared to others. In particular, the \(B_c^+ \to D^{*+}D^0\) and \(B_c^+ \to D^{*+}D^0\) decay modes have been proposed in \[24,32,38,41\] for the extraction of the CKM angle \(\gamma\) through amplitude relations.

### V. SUMMARY

In this work, we have studied the exclusive nonleptonic \(B_c \to (D_{(s)}, \eta_c, B_{(s)})M\) decays where the final state \(M\) mesons are factored out in the QCD factorization approach. The inputs used to obtain their branching ratios were the weak form factors for the semileptonic \(B_c \to (D_{(s)}, \eta_c, B_{(s)})\) decays in the whole kinematical region and the unmeasured weak decay constants obtained from our previous LFQM analysis \[13,44,45,48\]. For the measured values of decay constants, we use the central values extracted from the experimental measurements \[55,68,69\].

Our predictions for the branching ratios are summarized in Tables \[V\] and \[VI\] and compared with other theoretical results. Overall, the class II decay modes have more discrepancies among the theoretical models than the class I and III decay modes do. The upcoming experimental measurements of the corresponding decay rates can examine various theoretical approaches. The most promising measurable decay modes appear to be the CKM favored decays such as \(B_c^+ \to B_{s0}^0 (\pi^+, \rho^+)\)
decays. It is thus expected that the dominant contribution to the $B_c$ total rate comes from the $c$ induced decays. The more $c$ induced $B_c \to VP$ and $B_c \to VV$ decay modes seem to deserve further consideration.
