Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Association between Covid-19 surge and emergency department patient flow and experience

Crowding
Patient experience

ABSTRACT

Background: Preparations for Covid-19 in the Netherlands included hospital reconfigurations to increase capacity for the expected surge at the emergency department (ED). We describe patients’ ED length of stay (LOS), crowding and experiences of patients with respiratory complaints during the first Covid-19 peak.

Methods: Retrospective analysis of demand, ED LOS, crowding, and a patient experience survey during a 12-week period in 2020 and similar periods in 2018 and 2019. Crowding levels were calculated using the National ED OverCrowding Scale.

Results: The number of patients with respiratory complaints increased significantly, while total ED numbers were unchanged. Although presentation during the Covid-19 peak and needing hospital admission were associated with a longer ED LOS in patients with respiratory complaints, significantly less crowding occurred compared with the 2018 and 2019 periods. Increased ED LOS was associated with lower patient experience scores.

Conclusion: Advanced warning and its associated preparation within the hospital and the community prevented significant delays in ED throughput during the first Covid-19 peak.

1. Background

During the yearly returning influenza outbreaks, many patients present to emergency departments (EDs), potentially causing crowding. Adverse effects of ED crowding include delayed patient care, delayed critical interventions, and decreased patient satisfaction [1–4]. During the first Covid-19 peak in the Netherlands, early 2020, occurring simultaneously with the influenza season in the Netherlands, we feared substantial crowding. Warned by the Chinese and Italian experiences [5–7] we expected the ED being overwhelmed with patients suffering from shortness of breath and in need of hospitalization. Meanwhile, a decrease in number of hospital visits from patients with non-Covid-related complaints was reported internationally, probably due to measures such as the stay-at-home policy, hospitals delaying elective surgery, and people’s fear of getting infected [8].

The lay press in the Netherlands reported an increase in the number of patients with (suspected) Covid-19 infection and an increase in the number of hospitalizations, especially among older patients with underlying comorbidities. Regulations in the Netherlands focused on flattening the curve of new Covid-19 infections in order to have enough equipped Intensive Care Unit (ICU) beds and available staff. The Hospital Outbreak Management Team (OMT) undertook preparations to...
increase capacity of available inpatient beds on inpatient floors and ICUs and to provide a safe working environment for staff (Box 1).

The resulting impact on patient flow, ED crowding and patient experiences during this first Covid-19 peak are largely unknown. Patient experience is one of the performance measures used for healthcare quality evaluation and for setting priorities in quality improvement activities. Healthcare, even during a pandemic, must be safe, people-centred, timely and efficient [9]. To fulfill the ‘timely’ and ‘safety’ aspects, ED staff minimise waiting times for patients and reduce crowding. Both aspects are particularly challenging during a pandemic. Patients with suspected Covid-19 are isolated since the virus is highly contagious. Isolation negatively affects patient experiences [10]. ED staff need to wear protective gear that may create a feeling of discomfort for patients; the patient does not see the doctor and nurse behind the protective equipment, which may hinder building a relationship of trust [11]. This is especially important, as patients may fear that they are suffering from a potentially fatal disease.

The aim of this study was to describe changes in ED LOS, crowding and experiences of patients with respiratory complaints during the first Covid-19 peak in the Netherlands. We assessed patient experiences among patients with respiratory complaints, using the Manchester Triage System (MTS) as immediate (level 1), highly urgent (level 2), urgent (level 3), standard (level 4) or non-urgent (level 5). After triage, patients eligible for treatment by a general practitioner (GP) are redirected to a co-located GP cooperative (GPC). Remaining patients are assessed at the ED. Before February 2020, an ED nurse triaged patients arriving at the ED to the GPC or to the ED, following predefined criteria. From February 2020 onwards, a GPC assistant determined whether patients had to be directed to the GPC or ED, based on predefined criteria [12].

The usual 24/7 staffing on the ED includes emergency nurses, emergency physicians (EPs) and residents of the major specialties. During day and evening shifts, a nurse practitioner is available for patients with minor injuries and minor illnesses. During peak hours at the ED (from noon until eight pm), a cardiologist, an internal medicine specialist, a neurologist, a radiologist and a surgeon work side-by-side with the EPs and the residents. Other medical specialists are available in the hospital (office hours) and on-call (out-of-office hours) when consulted. During the 2020 study period, a pulmonologist was also available at the ED from five to eight pm, aiming for improved patient flow for patients with respiratory complaints.

2. Methods

2.1. Setting

This study was performed in a non-academic, inner-city teaching hospital in The Hague, a seaside city in the Netherlands, home to more than 500,000 people. The 30-bed ED serves as a regional level 1 trauma and acute neurovascular centre, and receives approximately 54,000 adult and paediatric patient visits annually. All patients who present at the ED are registered in the hospital database and subsequently triaged using the Manchester Triage System (MTS) as immediate (level 1), highly urgent (level 2), urgent (level 3), standard (level 4) or non-urgent (level 5). After triage, patients eligible for treatment by a general practitioner (GP) are redirected to a co-located GP cooperative (GPC). Remaining patients are assessed at the ED. Before February 2020, an ED nurse triaged patients arriving at the ED to the GPC or to the ED, following predefined criteria. From February 2020 onwards, a GPC assistant determined whether patients had to be directed to the GPC or ED, based on predefined criteria [12].

The usual 24/7 staffing on the ED includes emergency nurses, emergency physicians (EPs) and residents of the major specialties. During day and evening shifts, a nurse practitioner is available for patients with minor injuries and minor illnesses. During peak hours at the ED (from noon until eight pm), a cardiologist, an internal medicine specialist, a neurologist, a radiologist and a surgeon work side-by-side with the EPs and the residents. Other medical specialists are available in the hospital (office hours) and on-call (out-of-office hours) when consulted. During the 2020 study period, a pulmonologist was also available at the ED from five to eight pm, aiming for improved patient flow for patients with respiratory complaints.

2.2. Study design

The regional medical ethics committee and the institutional review board approved the study (METC LDD, N20.008).

We performed a descriptive mixed mode study using a retrospective chart review, in a 12-week period (26 January to 18 April 2020). We obtained data from the same periods in 2018 and 2019 to compare patient numbers and patient flow, for the general ED population and for the subgroup of patients with respiratory complaints, because there was
an awareness of Covid-19 as a respiratory disease [13-14]. Additionally, we performed a patient experience survey in the subgroup of patients with respiratory complaints presenting for Pulmonology during the Covid-19 outbreak. Patients with respiratory complaints were defined as patients who were assigned the category ‘Shortness of breath’ at triage. We excluded patients under the age of 18 and patients redirected to the GPC.

2.3. Chart review

We collected and recorded demographic details and visit characteristics (date and time of arrival, type of medical complaint, crowding level at arrival, triage level, date and time of ED discharge, and discharge disposition) in a de-identified database. Acuity level was categorized into urgent (immediate, high-urgent, and urgent) and non-urgent (standard and non-urgent). We calculated ED LOS by subtracting arrival time from discharge time. We measured the degree of crowding with the National ED Overcrowding Score (NEDOCS), a multidimensional scale ranging from zero to 200 [15]. The NEDOCS score accurately correlates with the degree of crowding as perceived by the ED staff at the study setting [16]. A computer programme calculates the NEDOCS scores at 15-min intervals. If the NEDOCS is 60 or higher, the ED is considered to be busy [15].

2.4. Patient experience survey

We measured patient experience in the patients with respiratory complaints who were assessed by Pulmonology during the first Covid-19 peak in 2020, using a survey based on the Picker Patient Experience Questionnaire (PPE-15) [17]. The survey was conducted by phone within three days of a patient’s ED visit. If the patient was not available or able to answer the phone, a spouse, caregiver, or family member was asked to participate. The survey included questions regarding patients’ experiences with waiting time, first contact with their physician, information supply, and communication. Questions had three to five response options (Appendix A). We coded neutral answers and the most positive answer as “non-problem”, and the remaining responses as “problems”. Overall patient experience (response to the question “Please rate your overall experience at our ED”) and likelihood of recommendation (response to the question “How likely would you be to recommend this ED to friends and family?”) were scored using a 10-point Likert scale. In 2018 and 2019, the same survey was used in a limited number of unsolicited patients from the general ED population.

2.5. Outcomes

Outcome variables were ED LOS, number of admitted patients experiencing a LOS of more than 4 h, crowding level at arrival of the patient as measured by the NEDOCS score, and number of patients arriving during extreme busyness (NEDOCS score between 60 and 100) and during crowding (NEDOCS score above 100). We describe all outcomes for the total study population as well as for patients with respiratory complaints, during the Covid-19 peak in 2020 and the matching periods in 2019 and 2018. For patients with respiratory complaints who were assessed by Pulmonology during the first Covid-19 peak, we additionally assessed their experiences during their visit and compared them with the experiences of the general population in 2019 and 2018.

2.6. Data analysis

We used descriptive statistics, Chi Square tests, and Kruskal-Wallis tests to compare the three years simultaneously.

To better understand factors associated with ED LOS we created multivariable linear regression models for the general ED population as well as for the patients with respiratory complaints, including study year, age, arrival time, and arrival by ambulance, referral status, triage level, and presenting problem in the models as potential covariates. ED LOS was log-transformed due to the non-normal distribution. Using backward stepwise selection, we subsequently removed the largest p-values until all p-values were smaller than 0.05.

Overall experience scores and recommendation scores of the patients with respiratory complaints arriving during the first Covid-19 peak were compared with the scores of the general population in 2018 and 2019. This latter analysis was solely considered hypothesis generating, since patient selection and survey procedures differed between the periods (e.g. by phone in 2020 vs. face-to-face in earlier years). We performed linear regression analyses to identify the association between patient experience scores, recommendation scores, patient characteristics and visit characteristics.

Significance thresholds were set at $p \leq 0.05$. We used the statistical package for the social sciences (SPSS Statistics for Windows 26.0 Armonk, New York, USA) for analysis.

3. Results

3.1. Patient characteristics

During the 12-week study period in 2020, 9274 ED visits were registered, which was similar to the total number of ED visits in the control periods (Table 1). Median age of patients was higher compared with the previous years. Arrivals by ambulance increased significantly and number of self-referrals decreased significantly.

The number of patients with respiratory complaints increased from 763 (in the 2018 study period) to 941 (in the 2020 study period), and the number of self-referrals decreased (Table 2). Admission percentage of respiratory patients varied from 57.4% in 2018, 51.8% in 2019, to 52.5% in 2020.

3.2. Patient flow

In the 2020 study period, median ED LOS was shorter for discharged patients and longer for patients who needed hospital admission, compared with the control periods, while the level of crowding reduced significantly (Table 3). In multivariable analysis, presentation in the 2019 and 2020 study periods, a higher age, transport by ambulance, referral by a GP, an urgent triage level, and needing hospital admission were significant predictors for a longer ED LOS, while arrival during the evening shift was associated with a shorter LOS. Presenting with a psychiatric disorder, feeling unwell, having abdominal complaints or shortness of breath was associated with a longer LOS (Table 4).

Focusing on the patients with respiratory complaints, we observed a significant increase in ED LOS for discharged patients compared with previous years. LOS for patients needing hospital admission and crowding levels were higher in the 2019 study period compared with 2018 and 2020 (Table 5). Presentation in the 2019 or 2020 study periods, a higher age, being referred by a GP, an urgent triage level, and needing hospital admission were significant predictors for a longer ED LOS (Table 6).

3.3. Patient experience survey

During the 12-week study period, 219 patients with respiratory complaints (response rate 35.7%) completed the survey. Compared with non-responders, respondents arrived more often during the day shift (60.3% vs. 51.6%), and were more often referred to the ED by their GP (53% vs. 44.3%). In the remaining characteristics and flow indicators, we observed no differences between responders and non-responders, suggesting that our respondent group was representative for the population with respiratory complaints (Appendix B).

A large proportion of the respondents indicated a lack of involvement in care and treatment decisions (76.2%). To the question, “Were you involved in the decision-making process concerning your
Medications could be further optimized to prevent readmissions.

| Treatment? â€” eighty-four of the 193 respondents (43.5%) answered “No, not at all”, and 63 of 193 respondents (32.6%) said “A little” (Table 7). Concerning discharge information, 64.8% of the respondents indicated a lack of information about when to proceed with normal activities, and 60.6% regarding information about ‘red flags’ to observe at home. Almost half of the patients reported problems with the waiting times between the diagnostic procedures (48.2%) and with the total ED LOS (47.2%). Respondents rated their ED experience with a mean of 7.72 (SD 1.42), similar to the mean experience scores in 2019 (7.75, SD 2.18, p = 0.335) and 2018 (8.08, SD 1.22, p = 0.129). The mean recommendation score in the 2020 group was 7.39 (SD 1.55), comparable with scores in 2019 (7.33 (SD 3.23, p = 0.915) and lower compared with 2018 (8.11 (SD 1.13), p = 0.006).
hospital admission was needed, \( p = 0.003 \). Increased total ED LOS was significantly associated with lower overall experience, with a 0.003-point decrease in every minute increase in LOS (\( p = 0.01 \)). Similar to overall experience, a longer ED LOS was associated with lower scores in likelihood to recommend; a 0.005-point decrease in score for every minute increase in ED LOS (Table 8).

4. Discussion

Our findings show that during the first Covid-19 peak in 2020, ED crowding decreased significantly. This was probably due to the system-wide collective response and hospital preparations which increased resources for the ED, and public health messaging, which may have decreased ED visits in some patient groups.

4.1. Patient flow

In 2020, we expected a surge in seriously ill patients due to Covid-19, occurring during the yearly influenza season. Warned by the testimonials and images on television of the dramatic circumstances in other countries and early research reports [5–7], our OMT initiated preparations to increase capacity for our influenza and Covid-19 patients and to provide a safe working environment for our staff. During the first Covid-19 peak, we observed no change in total number of ED visits in the 2020 period compared with previous years, while simultaneously more ED and ICU staff and resources were available. The 2020 influenza season in the Netherlands was relatively mild and lasted only 5 weeks, partly overlapping with the first Covid-19 peak. The 14-week lasting influenza season in 2019 was severe, probably explaining the higher ED LOS for admitted patients and the high crowding levels in the 2019 period compared with the 2020 period.

In the Netherlands as well as internationally, researchers reported a decrease in number of patients with non-Covid-related complaints, explained by regulations (stay-at-home policy, reduced community activity such as sports which reduces injuries), hospital management postponing elective surgery, and patients who avoid medical care out of fear of contracting the virus [8]. This coincides with our findings: the number of total ED visits remained unchanged because the number and proportion of patients with respiratory complaints increased while simultaneously a decrease in patients with other complaints occurred. For example, significantly less patients with chest pain and syncope arrived at our ED during the first Covid-19 peak. Other studies also found reductions in admission for acute coronary syndromes, even in areas not heavily affected by the outbreak [18].

Public health messaging was both a promise and a curse in that it decreased ED volume but may be associated with increased morbidity and mortality in the community for non-COVID illnesses [19–20]. Some studies suggest a decline in ED attendances mainly due to patients with minor injuries and minor illnesses [21], but these patients were excluded in our study, since they are assessed at the GPC.

The higher proportion of arrivals by ambulance and lower proportion of self-referrals compared with the control periods suggests a sicker population in the 2020 period, which may partially be an effect of the change of the triage process of self-referrals in February 2020. The unchanged admission percentage argues against this, however, we cannot rule out that physicians used different admission and discharge thresholds during the Covid-19 peak.

The LOS of patients with respiratory complaints who were discharged home during the Covid-19 peak was significantly longer compared with the control periods. We hypothesize that the use of isolation procedures may have negatively impacted ED LOS, as shown by Beyssard et al. [22]. During the control periods, ED staff applied isolation procedures in patients with suspected or confirmed influenza. In 2020, ED staff worked in protective gear when approaching the majority of patients, considering all patients with suspicious complaints as potentially Covid-19 positive. Test results, only available when patients needed hospital admission, took at least one day.

4.2. Patient experiences

Comparing patient experiences between different years is difficult: patient selection and survey procedures differed between the periods. Moreover, during the first Covid-19 peak, we introduced a variety of process changes, with more ED staff and available resources, which may have influenced patient experiences. The drop in crowding could have led to higher patient experience scores as suggested in other studies [4]. Unfortunately, experience scores were unchanged, and recommendation scores were lower. Likely, ED staff were less often present in the patients’ room because the use of protective gear is time-consuming. Moreover, staff had to be very careful with the protective gear, because of an imminent shortage. The isolated circumstances may have led to lower patient scores.

The score for overall experience was highly correlated with likelihood to recommend, similar to the findings of Nichol et al [23]. Patient satisfaction can be seen as the gap between patients expectations and experience [24]. Worse experience may reflect suboptimal care or different expectations of care quality [25]. Patients who needed hospital
admission had higher scores in overall experience compared with discharged patients. Discharged patients may have been disappointed in not getting a Covid-19 test. Covid-19 tests were scarce during the first Covid-19 peak, only available if hospital admission was necessary.

Increased ED LOS was significantly associated with lower overall experience and lower scores in likelihood to recommend, similar to findings from Nyce et al. [26]. Although waiting times and LOS in our ED are relatively short, compared with international standards [27–29], waiting is difficult for patients [26,30]. Maybe it is even more difficult during a pandemic, when less distraction and communication is possible. For example, family was not allowed in the assessment rooms and ED staff comes in less often. Interestingly, acuity based on the MTS may present with many other symptoms such as fever and abdominal pain during a pandemic, when less distraction and communication is possible. For example, family was not allowed in the assessment rooms and ED staff comes in less often. Interestingly, acuity based on the MTS may present with many other symptoms such as fever and abdominal pain.

The vast majority of our patients reported problems with the item of patients’ involvement in care. This finding may be not surprising during a crisis situation, although similar findings were found in a Norwegian study from 2017 [25]. According to our findings, we should focus on shared decision-making, on providing discharge information, and on decreasing patients’ waiting times between diagnostic procedures and on decreasing total ED LOS.

5. Limitations

Our study includes data from a single level-one hospital, located in the Netherlands. Patients in our country have 24/7 access to primary care services, which enables EDs to focus on rapid assessment and emergency stabilisation of seriously ill and injured patients. Generalizability of our findings cannot be assumed in countries with different healthcare systems and in hospitals which were more heavily impacted by the outbreak.

We identified patients with respiratory complaints by selecting the patients who were assigned the triage category ‘Shortness of breath’. This group is an underestimation of the total group of patients with suspected Covid-19 infection, since patients with a Covid-19 infection may present with many other symptoms such as fever and abdominal complaints. Although some of our patients may have presented with chronic respiratory diseases, all patients with shortness of breath were assessed within the Covid-19 guidelines, and thus considered ‘suspected Covid-19’.

Finally, this was a descriptive study using retrospective data. Although the quality of the data is high, associations do not entail causality.

6. Implications for further research

We could not include all factors in the regression analysis that may have influenced patients’ experiences, such as whether or not the patient was isolated at the ED, received testing or not, and (the number of) individual patient/provider interactions. It would be interesting to assess the effect of isolation procedures and contact moments with professionals on patients’ experience in a future study.

Crowding scores in our study, measured with the NEDOCS instrument, do not necessarily match nursing workload. Wearing protective gear, to be changed for every patient, limits productivity [31]. Protocols regarding protective gear, diagnostics and treatment were regularly adapted based on new information, thereby causing an overload of information to the ED staff [5,31]. The fear of becoming infected and the fear of being contagious and infecting others may aggravate perceived workload [32]. Further research is needed on provider outcome and experiences when caring for patients in respiratory isolation.

7. Conclusions

Advanced warning and its associated preparations within the hospital and the community prevented significant delays in ED throughput during the first Covid-19 peak. The increase in number of patients with respiratory complaints was combined with a drop in some other patient groups. Although presentation during the Covid-19 peak and needing hospital admission were associated with a longer ED LOS in patients with respiratory complaints, significantly less crowding occurred.

Ethical Statement

All procedures performed in this study were in accordance with the 1964 Helsinki Declaration and its later amendments or comparable ethical standards.

The ethical review committee of Southwest Holland granted approval and exemption. Patient consent was not required.

Funding source

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.
