Abstract

In this paper we show how the equations of motion of a superfield, which makes its appearance in a path-integral approach to classical mechanics, can be derived without the need of the least-action principle.

Keywords: Lagrangian and Hamiltonian Mechanics, Path-Integrals Method

1. Introduction

In the 30’s Koopman and von Neumann (KvN) gave an operatorial approach to classical mechanics (C.M.) \cite{Koopman}. In the late 80’s a functional (path-integral) counterpart of the KvN was proposed \cite{KvN}. To distinguish this path-integral from the quantum one we will use the acronym CPI (classical path-integral) for the first and QPI for the second. The difference is that while the QPI gives a weight \( \exp \left( \frac{i}{\hbar}S[q(t)] \right) \) to every path, the CPI gives weight one to the classical paths and weight zero to the others.

Indicating with \( \varphi^a(t) \) the points in phase space

\[
\varphi^a = (q^1, \ldots, q^n; p^1, \ldots, p^n)
\]

and with \( H(\varphi^a) \) the Hamiltonian, the eqs. of motion are:

\[
\dot{\varphi}^a = \omega^{ab} \frac{\partial H}{\partial \varphi^b}, \quad (1)
\]

where \( \omega^{ab} \) is the symplectic matrix \cite{Gozzi}. The CPI has a generating functional of the form:

\[
Z[0] = \int D\varphi^a \delta \left[ \varphi^a - \varphi^a_0(\varphi_0; t_0; t) \right] \quad (2)
\]

where \( \varphi^a_0(\varphi_0; t_0; t) \) are the solutions of the eq. of motion \textsuperscript{(4)} with some initial condition \( \varphi_0 \). The integration \( D\varphi^a \) is the functional integration, including an integration overall possible initial configurations \( \varphi^a_0 \). The \( \delta \ldots \) is a functional Dirac-delta which gives weight “one” to the classical solutions and “zero” to all the others. We can rewrite \textsuperscript{(2)} as

\[
Z[0] = \int D\varphi^a \delta \left[ \varphi^a - \varphi^a_0(\varphi_0; t_0; t) \right] = \int D\varphi^a \delta \left[ \varphi^a - \omega^{ab} \frac{\partial H}{\partial \varphi^b} \right] \det \left( \delta_{ab} \delta_i - \omega^{al} \frac{\partial^2 H}{\partial \varphi^b \partial \varphi^l} \right). \quad (3)
\]

Let us perform a Fourier transform of the Dirac delta appearing in \textsuperscript{(3)} introducing 10 extra variables \( \lambda_i \) and let us exponentiate the determinant using a set of 4 Grassmann variables \( c^a \) and \( \tilde{c}^a \) (with \( a = 1, \ldots, 2n \)). The final result is the following:

\[
Z[0] = \int D\varphi^a D\lambda_i Dc^a D\tilde{c}^a \exp \left[ i \int dt \tilde{\mathcal{L}} \right] \quad (4)
\]

where

\[
\tilde{\mathcal{L}} = \lambda_a \varphi^a + i \bar{c}^a \partial_t \varphi^a - \lambda_a \omega^{ab} \partial_t H - i \bar{c}^a \omega^{ab} \partial_t \partial_q H \partial_q \varphi^b. \quad (5)
\]

In this formulation of C.M., we passed from 2\( n \) variables \( \varphi^a \) to 8\( n \) ones which are \( (\varphi^a, \lambda_i, c^a, \tilde{c}^a) \) and from the standard lagrangian of C.M.

\[
L = \frac{1}{2} \varphi^a \omega^{ab} \varphi^b - H(\varphi^a) \quad (6)
\]

where

\[
\varphi^a(t, \theta, \bar{\theta}) = \varphi^a(t) + \theta \epsilon^a(t) + \partial_t \omega^{ab} \tilde{c}_b(t) + i \bar{\theta} \omega^{ab} \lambda_b(t). \quad (7)
\]
This is a sort of multiplet which put together all the 8n variables \((\varphi^a, \lambda_n, \tilde{c}, \tilde{c}_a)\) and it is known in supersymmetric jargon as ”superfield”. It is easy to prove that:

\[
\hat{L}(\varphi, \lambda, c, \tilde{c}) = i \int d\theta d\bar{\theta} L[\Phi] + \text{(s.t.)},
\]

where \(\hat{L}\) is the lagrangian in (5) while \(L\) is the lagrangian in (6) but with the superfield \(\Phi^a\) replacing \(\varphi^a\) and (s.t.) is a surface term. The generating functional (4) can then be written as

\[
\mathcal{Z}[0] = \int D\Phi \exp \left[ i \int i d\theta d\bar{\theta} L[\Phi] \right],
\]

which strongly resembles the one of the QPI. For more details see ref. [4].

2. Equation of motion

In ref. [2] and [3] we wrote that the equations of motion for the 8n variables could be derived from \(\hat{L}\) of eq. (5) or, via the superfield, from \(L[\Phi^a]\). We somehow assumed a least-action principle for the lagrangians \(\hat{L}(\varphi, \lambda, c, \tilde{c})\) or \(L[\Phi]\). In this paper we will show that there is actually no reason to assume this principle which usually holds only for \(L[\varphi^a]\) and provides the correct equation for only \(\varphi^a\). Using this principle for \(\hat{L}(\varphi, \lambda, c, \tilde{c})\) we got the eqs. of motion not only for \(\varphi^a\) but also for \(\lambda_n, c^d, \tilde{c}_a\). They are:

\[
\begin{align*}
\delta \varphi^a &= \epsilon \epsilon^a \\
\delta c^d &= i \epsilon \lambda_n \\
\delta \tilde{c}_a &= \delta \lambda_a = 0
\end{align*}
\]

These are the first two eqs. of the set represented in (9). How do we get the last two eqs. for \(\tilde{c}_a\) and \(\lambda_a\)?

3. Ward Identities

\(\hat{L}\) has some BRS and anti-BRS like invariances [2] which have the form:

\[
\begin{align*}
\text{BRS:} \quad &\delta \varphi^a = \epsilon \epsilon^a \\
\text{anti-BRS:} \quad &\delta c^d = i \epsilon \lambda_n \\
\end{align*}
\]

with \(\epsilon, \bar{\epsilon}\) anti commuting parameters. In a path-integral the symmetries can be used to derive what are called the Ward identities. These are derived in the following manner: let us take an arbitrary quantity \(O(\varphi, c, \tilde{c}, \lambda)\) and let us do a symmetry variation of it: \(\delta O(\varphi, c, \tilde{c}, \lambda)\). It is easy to prove that

\[
\langle \delta O \rangle = 0
\]

where \(\langle \ldots \rangle\) means an average performed via \(\mathcal{Z}[0]\). The proof of the relation above can be found in any book on field theory. Let us choose for \(O\) the following quantity

\[
O \equiv \varphi^a - \epsilon \epsilon^a \bar{\rho}_b H
\]

and as symmetry variation the anti-BRS of eq. (13). We get as Ward identity:

\[
\langle \delta O \rangle \equiv \langle \delta \varphi^a - \epsilon \epsilon^a \bar{\rho}_b H \delta \varphi^a \rangle = -\bar{\epsilon} \epsilon^a \langle \{ \tilde{c}_b + \bar{\rho}_b \bar{\rho}_d H \omega^c \tilde{c}_c \} \rangle = 0,
\]

which implies

\[
\langle \{ \tilde{c}_b + \bar{\rho}_b \bar{\rho}_d H \omega^c \tilde{c}_c \} \rangle = 0.
\]

If we now use as a path integral over which to perform the average in (14) the expression (10), which does not
depend on \( \dot{c} \), this variable can be pulled out of the path-
integral, while the \( \varphi \) entering (14) will sit on the classical
trajectory as required by (10). Doing this we get from (14) exactly
the equation of motion of \( \dot{c} \):

\[
\dot{c}_b + \partial_b \partial_\theta H \omega^{ed} \dot{c}_e = 0.
\]

This is the manner to get the eq. of motion for \( \dot{c} \) via our
path-integral.

The last equation in (9) that we have to derive is the one for \( \lambda \). We will get also this one via Ward-identities.

Let us choose as \( O \) the quantity:

\[
O \equiv c^a - \omega^{ab} \partial_b \partial_\theta H c^b
\]

and let us build the \( \langle \delta O \rangle \) where the variation we use is the anti-BRS of (13)

\[
\langle \delta O \rangle = \left( \delta c^a - \omega^{ab} \partial_b \partial_\theta (\delta H) c^d - \omega^{ab} (\partial_\theta \partial_b H) \delta c^d \right)
\]

\[
= -i \bar{\theta} \omega^{ab} \left( \lambda_b + i \partial_b \partial_\theta H \omega^{ed} \bar{c}_f \right) c^d + \partial_\theta \partial_b H \omega^{ed} \lambda_e = 0.
\]

As before let us choose as generating functional the one in (10). As this one does not depend on \( \lambda, \dot{c} \), these variables in (15) can be pulled out of the average \( \langle \ldots \rangle \), while the \( \varphi, c \) will be forced on their classical trajectory by (10).

The result is:

\[
\lambda_b + i \partial_b \partial_\theta \partial_\theta H \omega^{ef} \bar{c}_f c^d + \partial_\theta \partial_b H \omega^{ed} \lambda_e = 0,
\]

which is the equation of motion for \( \lambda \) appearing in (9).

We have done confirms that we do not need to use any least action principle to get the full set of the 8n
eqs. of motion but just our path-integral (CPI) and its
symmetries.

4. Equations of motion of the superfields

The eqs. of motion (9) which we found are equivalent
to the following superfield eqs:

\[
\Phi^a = \omega^{ab} \frac{\partial H(\Phi)}{\partial \Phi^b}
\]

In fact expanding both sides of (16) in \( \theta, \dot{\theta} \) we get:

\[
\dot{\varphi} = \omega^{ab} \partial_\theta H + \theta \left[ \dot{c}^a - \omega^{ab} \frac{\partial^2 H}{\partial \varphi^b \partial \varphi^c} c^c \right] + \dot{\theta} \omega^{ab} \left( \dot{c}_b + \partial_b \partial_\theta H \omega^{ed} \dot{c}_e \right) c^d + \partial_\theta \partial_b H \omega^{ed} \lambda_e = 0.
\]

and for this to be zero each coefficient of \( \lambda, \dot{\lambda}, \dot{\theta}, \dot{\theta} \) must be zero. These coefficients are exactly the eqs. of motion appearing in (9). So eq. (16) is a compact way to

rewrite the full set of eq. (9). By looking at (16) the
reader may think it was derived via a least action principle
from the generating functional appearing in (8) but there is no reason to use the least action principle in that path-integral. We derive the eqs. (9) as we have done before by using only our path-integral and its symmetries and then we sum up all the eqs. (9) like it is done in (17) via the \( \perp, \theta, \dot{\theta}, \dot{\theta} \). This sum is zero because each term is zero and this sum is exactly the superfield eq. (16). So we conclude that also for the superfield eq (16) we do not need any least action principle despite their strong resemblance to the Hamilton eq. for \( \varphi^a \).

5. Conclusions

In this paper we have derived the eqs. of motion of all the 8n fields \( (\varphi^a, \epsilon^a, \epsilon_\theta, \lambda_b) \) appearing in the CPI. We have done so without using neither the least action principle, which has no reason to be in a path-integral formalism, nor the saddle point technique that has no reason to be because we do not have any small parameter in classical mechanics. These 8n equations can be summed up into 2n compact equations for the superfield \( \Phi^a \). The evolution of these super fields is identical to the Hamilton eqs. for \( \varphi^a \) but, differently than these, they do not need any least action principle to be derived from. The only tools that we used, and that are allowed in our formalism, are the classical path-integral and its associated symmetries.
