Abstract—Adsorption efficiency, kinetic and thermodynamic studies of the adsorption of Malachite green oxalate onto activated carbon from snail shell was carried out. The cleaned Snail shell was carbonized at 400°C, crushed and sieved before it was activated with 0.1m HCl at 800°C in a furnace. Batch adsorption experiment was carried out at variable concentration, time and temperature while other factors are kept constant. The adsorption isotherms used show that the correlation coefficient of Freundlich isotherm is closer to unity compare to that of Langmuir isotherm. The adsorption follows the Pseudo second order kinetic with adsorption capacity of 1.7544 (mg/g) and rate constant of 0.471(g/mg.min). The thermodynamic parameters: change in enthalpy, $\Delta H = 15.90$ KJ/mol, change in entropy $\Delta S = 60.16$J/mol. K and the change in Gibbs free energy $\Delta G = -1.69, -2.98, -3.64, -3.24, -3.43$ and $-3.51$ KJ/mol at 303, 308, 313, 318, 323 and 328K respectively. These results show that activated carbon from snail shell has the potential of a good low cost adsorbent for the removal of this hazardous dye from wastewater.

Keywords— Adsorption, kinetic, Malachite green oxalate, snail shell, thermodynamic.

I. INTRODUCTION

The textile, paper, printing and dye industries consume large quantities of water at its different steps of dyeing and finishing processes. Due to the large volume of water consumption, the production of huge volume of wastewater is inevitable. Generally, the wastewater from printing and dyeing units in these plants contain residue of dyes and chemicals [5]. The presence of these dyes in wastewater is not desirable because of their toxic nature to the life and environment into which they are discharged. Therefore, the removal of such compounds from wastewater is a vital task.

Adsorption process using activated carbons is widely used to remove pollutants from wastewaters. However, commercially available activated carbon is expensive. In the last years, special emphasis on the preparation of activated carbons from several agricultural by-products has been given, due to the growing interest in low cost activated carbons from renewable, copious, especially for application concerning treatment of wastewater. Researchers have studied the production of activated carbon from palm-tree cobs, plum kernels, cassava peel, bagasse, jute fiber, rice husks, olive stones, date pits, fruit stones and nutsells [2]. In this study, the ability of snail shell carbon to remove Malachite green oxalate by adsorption is been studied. The Langmuir and Freundlich isotherms will used to fit the equilibrium data. Pseudo-first order and pseudo-second order models will be used to fit the experimental data and the thermodynamic study will also be carried out [3].

II. THEORY

2.1 Adsorption kinetics

The pseudo first order and second order kinetic models need to be tested to determine which model is in good agreement with experiment adsorption capacity ($q_e$) value, thus suggesting which model the adsorption system follows.

2.1.1 Pseudo-first order equation

The Largergren model assumes a first order adsorption kinetics and can be represented by the equation.

$$\frac{dq_e}{dt} = K_t(q_e - q_t)$$ (1)

Log ($q_e - q_t$) = Log($q_e$) - $\frac{K_t}{2.303}t$ (2)

The values of Log ($q_e - q_t$) were linearly correlated with time t. The plot of Log ($q_e - q_t$) versus t should give a linear relationship from which $K_t$ and $q_e$ can be determined from the slope and intercept of the plot, respectively.

2.1.2 Pseudo-second order equation

The pseudo-second-order adsorption kinetic rates equation is expressed as
The Freundlich isotherm is an empirical relationship which often gives a more satisfactory model of experimental data. It can be expressed as follows:

$$\log q_e = \log (K_f) + \frac{1}{n} \log C_e$$

(8)

Where $C_e$ and $q_e$ are equilibrium concentration and adsorption capacity at equilibrium stage, while $K_f$ and $n$ are Freundlich constants which incorporates all factors affecting the adsorption process (adsorption capacity and intensity). Values of $K_f$ and $n$ can be obtained from the intercept and slope of a plot of adsorption capacity, $q_e$, against equilibrium concentration $C_e$ [8].

III. MATERIALS AND METHODS

3.1 Preparation of adsorbent

Sample of snail shells were picked from the environment in Elele, Rivers State, Nigeria. The snail shells were washed with tap several times to remove the dust and other water-soluble materials. The process continues until the washing water was colorless, then dried in the open air. The dried snail shells were carbonized in a furnace (SX-5-12) at 400°C for 3 hours, the charred were allowed to cool to room temperature and ground. 100 gram of the ground carbonized snail shells was added to 300 ml of 0.1M HCl solution, thoroughly mixed and heated until it formed slurry. The slurry was transferred to a crucible and heated in a furnace (SX-5-12) at 800°C for 3 hours, allowed to cool to room temperature and washed with de-ionized water, dried in an oven at 110°C for 2 hours [7].

3.2 Preparation of adsorbate

The malachite green oxalate used is of laboratory grade (KEM LIGHT, India). The solution was prepared in de-ionized water from Ion-exchange (Indian) Ltd, Eleme, Port Harcourt, Nigeria. 150mg of the dye was dissolved in 1000ml of de-ionized water to prepare the standard solution. Experimental solutions of the desired concentrations were obtained by successive dilutions with de-ionized water.

3.3 Adsorption experiment

1000mg of the activated carbon of snail shell was mixed with 50ml of malachite green oxalate solution of the desired concentrations (25, 50, 75, 100, 125 and 150mg/L) at 30°C in a temperature controlled water bath with constant shaking. The samples were withdrawn after 30 minutes and dye solutions were separated from the adsorbent using Whatmann filter paper. The concentration of the filtrate was measured with a UV spectrophotometer (2OD) at 618nm. The experiment was repeated using 1000mg of the activated carbon with 50ml of 50mg/L concentration of malachite green oxalate solution at 30°C in a temperature controlled...
water bath with constant shaking. The samples were withdrawn after 30, 60, 90, 120, 150 and 180 minutes respectively and filtered using Whatmann filter paper. The concentration of the filtrate was measured with a UV spectrophotometer (2OD) at 618 nm. Again 1000 mg of the activated carbon mixed with 50 ml of 50 mg/L concentration of malachite green oxalate solution at 30, 35, 40, 45, 50 and 55°C in a temperature controlled water bath (DK – 420) with constant shaking was also carried out. The samples were withdrawn after 30 minutes respectively filtered and the concentration measured.

The adsorption amount of malachite green oxalate dye adsorbed onto the snail shell adsorbent at equilibrium was calculated with the following equation:

$$q_e = \frac{(C_0 - C_e)V}{X}$$  

(11)

Where $C_0$ (mg/L) and $C_e$ (mg/L) are the initial and equilibrium concentration of the dyes, $V$ (L) is the volume of solution, $X$ (g) is the weight of adsorbent in one container.

The percentage of snail shell adsorbed was calculated as:

$$\% \text{ adsorbed} = \left(\frac{C_0 - C_e}{C_0}\right) \times 100$$  

(12)

IV. RESULTS

The results of the adsorption experiment are presented graphically in the figures below.

V. DISCUSSION

The efficiency of the adsorption presented in table 1, shows that adsorption increases as time increases until 120min when the active sites were filled, then the adsorption efficiency becomes constant. The table also shows that adsorption increases with increase temperature, but after 35°C, increasing the temperature will no longer be economical. As the concentration of the adsorbate is increased, the efficiency of adsorption decreases, though highest at 25mg/l, but it is more economical with 50mg/l.

The values of the adsorption models presented in table 2 shows that the correlation coefficient of Freundlich isotherm is closer to 1 than that of Langmuir, indicating that it a heterogeneous adsorption process.

The kinetic of adsorption of Malachite green oxalate onto snail shell was studied using pseudo first-order and second-order equations for the examined system. The pseudo second-order kinetic model provided the best correlation for the experimental data.

From the thermodynamic point of view, the positive value of \(\Delta H\) indicates that the adsorption of Malachite green oxalate on snail shell is endothermic and a physical process. The positive value of \(\Delta S\) shows the existence of structural changes at the solid–liquid interface and \(\Delta S\) favors ion exchange and stability of adsorption.

VI. CONCLUSION

From the adsorption efficiency, kinetic and thermodynamic studies of the adsorption of Malachite green oxalate onto activated carbon from snail shell studied, the results obtained from the analysis show that snail shell has good potential as low cost adsorbent for the removal of this hazardous dye from wastewater.
