Affiliated Hospital of Nantong University, Nantong, China

**Objectives**

Recently, high failure rates of metal-on-metal (MOM) hip implants have raised concerns of cobalt toxicity. Adverse reactions occur to cobalt nanoparticles (CoNPs) and cobalt ions (Co^{2+}) during wear of MOM hip implants, but the toxic mechanism is not clear.

**Methods**

To evaluate the protective effect of zinc ions (Zn^{2+}), Balb/3T3 mouse fibroblast cells were pretreated with 50 μM Zn^{2+} for four hours. The cells were then exposed to different concentrations of CoNPs and Co^{2+} for four hours, 24 hours and 48 hours. The cell viabilities, reactive oxygen species (ROS) levels, and inflammatory cytokines were measured.

**Results**

CoNPs and Co^{2+} can induce the increase of ROS and inflammatory cytokines, such as tumour necrosis factor α (TNF-α), interleukin-1β (IL-1β) and interleukin-6 (IL-6). However, Zn pretreatment can significantly prevent cytotoxicity induced by CoNPs and Co^{2+}, decrease ROS production, and decrease levels of inflammatory cytokines in Balb/3T3 mouse fibroblast cells.

**Conclusion**

These results suggest that Zn pretreatment can provide protection against inflammation and cytotoxicity induced by CoNPs and Co^{2+} in Balb/3T3 cells.

**Keywords:** Cobalt cytotoxicity, Protective effects, Zinc, Cobalt nanoparticles, Cobalt ions

---

**Article focus**

- The use of cobalt-chromium metal-on-metal (MOM) hip arthroplasty causes a new source of cobalt exposure, induced wear particles in nanometric size and metal ions.
- Cytotoxicity was observed in cobalt ions (Co^{2+}) and nanoparticles (CoNPs).
- The study aimed to investigate whether zinc protects cells from the cytotoxic effects of Co^{2+} and CoNPs derived from MOM joint arthroplasties.
- Zn pretreatment can provide protection against CoNPs and Co^{2+} induced cytotoxicity and inflammation in Balb/3T3 mouse fibroblast cells.

**Strengths and limitations**

- Strengths: this study confirmed that 50 μM Zn could decrease CoNPs- and Co^{2+}-induced cytotoxicity, ROS production and inflammatory cytokines.
- Limitations: future research should focus on clinically relevant experimental research in vivo.

**Introduction**

With the introduction of the metal-on-metal (MOM) bearings to hip resurfacing, the use of cobalt-chromium (Co-Cr) MOM hip arthroplasty has caused a new source of Co
exposure. Co-containing metal alloy releases a large number of metal debris particles and metal ions. Co and Cr ions have been detected in solution during corrosion of metal alloys. Furthermore, there is an increase in circulating metal ions in the blood of MOM hip arthroplasty patients, which may be exposed to metal for many years post-operatively.

Co nanoparticles (CoNPs) are of special toxicological importance because of the ability of the nanoparticles to directly enter cells and cause subsequent tissue damage. Due to the possible risks for human health, the toxic effects of CoNPs and Co ions (Co2+) have attracted widespread attention. However, the precise mechanism of Co-induced toxicity is still unknown. Among the proposed potential mechanisms, reactive oxygen species (ROS) and oxidative stress were thought to induce cytoxicity and genotoxicity. ROS are not only a key factor in the apoptosis process but also play an important role in DNA damage and other cellular processes. The toxicity of metal oxides may also be dependent on the extent of oxidative stress. In other words, the cellular redox status and the imbalance between oxygen free radical generation and detoxification can influence the apoptosis process. In addition, CoNPs and Co2+ not only cause cytotoxicity and genotoxicity but also induce an inflammatory response.

Preparation of Co nanoparticle and Co2+ solutions. CoCl2·6H2O was dissolved in ultrapure water at 10 mM concentration, and diluted in culture medium to achieve the required working concentrations (1 μM, 5 μM, 10 μM, 50 μM, 100 μM, 500 μM). The CoNPs samples were suspended in ultrapure water at the initial concentration of 1000 μM, sonicated in a sonicator bath at room temperature for 30 minutes at 40 W in order to minimise particle aggregates and finally diluted with complete culture medium to the final working concentrations (1 μM, 5 μM, 10 μM, 50 μM, 100 μM, 500 μM). The freshly prepared stock solution was processed three times by sonication immediately before exposure to cells.

Cell culture and sample treatment. Balb/3T3 mouse fibroblast cells were procured from the China Center for Type Culture Collection (Shanghai, China). Cells were cultured in DMEM medium supplemented with 10% FBS and 100 U/ml penicillin–streptomycin at 5% CO2 and 37°C in a humidified atmosphere. At 85% confluence, cells were harvested by using 0.25% trypsin and were plated into 60 mm dishes or 96-well plates according to the type of experiment. Cells were allowed to attach to the surface for 24 hours prior to treatment. For the dose-related experiments, the cells were exposed to CoNPs and Co2+ for four, 24 and 48 hours. To examine the protective effects of Zn ions (Zn2+) on the viability of cells, the cells were pretreated with 50 μM Zn2+ for four hours and subsequently exposed to varying concentrations of CoNPs and Co2+ for 24 hours. The cells were randomly divided into six groups: control group (Balb/3T3 cells treated with normal medium), CoNPs group, CoNPs + 50μM Zn2+ group, Co2+ group, Co2+ + 50 μM Zn2+ group and 50 μM Zn2+ group.

Cell viability assay. The cytotoxicity of Balb/3T3 cells was analysed by the CCK8 assay according to the manufacturer’s protocol. Balb/3T3 cells grown in 96-well culture plates were treated with the agents for various time periods and washed twice with medium. The CCK-8 solution (10 μl) was immediately added to 100 μl of a culture medium per well and the cells were then incubated for an additional 2 hours at 37°C in a humidified atmosphere of 5% CO2 and 95% air. The absorbance of each sample was measured at 450 nm by a microplate reader (Japan Intermed, Tokyo, Japan). The cell viability
Cells were incubated with DCFH-DA for 30 minutes at 37°C in a 5% CO₂ incubator. Following completion of the reaction, the reaction mixture was washed three times by 200 μl of phosphate-buffered saline in each well. The fluorescence intensity of the cell was measured on a multi-well microplate reader (Japan Intermed) using excitation and emission of 485 nm and 525 nm, respectively. Values were expressed as the percentage of fluorescence intensity relative to the control wells. **Detection of cytokines.** Cytokines levels were measured by collecting the supernatants from cell cultures at 24 hours after the cells were exposed to Co²⁺ and CoNPs groups. The concentrations of TNF-α, IL-1β and IL-6 in the culture media were determined using ELISA kits according to the manufacturer’s instructions. Each sample was analysed in triplicate.

In order to evaluate the protective effect of Zn²⁺ pretreatment, cells were pretreated with 50 μM Zn²⁺ for four hours. Then, the cells were exposed to different concentrations of Co²⁺ and CoNPs for 24 hours. Values were collected as described above. **Statistical analysis.** This was performed using SPSS 19.0 (IBM Corp, Armonk, New York). Data were analysed by one-way analysis of variance followed by Tukey’s post hoc test. Results shown summarise data from three independent experiments and were represented as the mean ± standard deviation (sd). Differences between groups were considered significant if p-values < 0.05.

**Results**

**Effect of Zn²⁺ on cell viability in Balb/3T3 cells.** As shown in Figure 1, CoNPs and Co²⁺ induced a concentration- and time-dependent reduction in the viability of Balb/3T3 cells. Whilst 10 μM Co²⁺ did not significantly affect cell viability at four hours, >50 μM Co²⁺ significantly decreased cell viability. Whereas 5 μM CoNPs had no influence on cell viability, >10 μM induced reduction of cell viability (Fig. 1a). At 48 hours, 50 μM Co²⁺ had a significant reduction of cell viability and 5 μM CoNPs induced reduction of cell viability (Fig. 1c). The inhibitory concentration 50 values at 24 hours were approximately 50 μM CoNPs and 100 μM Co²⁺, respectively (Fig. 1b). Therefore, those concentration values were used for the subsequent tests. Our results showed that pretreatment with 50 μM Zn exhibited significant protective effects on the cell viability (p < 0.05), which showed 51.36% (sd 5.09) and 67.91% (sd 6.97) increased survival respectively, compared with that in Co²⁺ and CoNPs treated cells. In addition, pretreatment with 50 μM Zn²⁺ did not show cytotoxicity and in fact an increase in cell viability was observed (Fig. 2).

**ROS measurement.** Spectrofluorometry analysis was used to assess ROS generation in cells exposed to target concentrations of CoNPs and Co²⁺ and the protective effects of Zn²⁺ pretreatment. For the spectrofluorometry analysis, cells (1 × 10⁵/well) were seeded in 96-well plates. Before the cells were exposed to CoNPs and Co²⁺ at target concentrations for 24 hours, the cells were pre-treated with 50 μM Zn²⁺ for four hours. After exposure, cells were incubated with DCFH-DA for 30 minutes at 37°C in a 5% CO₂ incubator. Following completion of the reaction, the reaction mixture was washed three times by 200 μl of phosphate-buffered saline in each well. The fluorescence intensity of the cell was measured on a multi-well microplate reader (Japan Intermed) using excitation and emission of 485 nm and 525 nm, respectively. Values were expressed as the percentage of fluorescence intensity relative to the control wells. **Detection of cytokines.** Cytokines levels were measured by collecting the supernatants from cell cultures at 24 hours after the cells were exposed to Co²⁺ and CoNPs groups. The concentrations of TNF-α, IL-1β and IL-6 in the culture media were determined using ELISA kits according to the manufacturer’s instructions. Each sample was analysed in triplicate.

**Results**

**Effect of Zn²⁺ on cell viability in Balb/3T3 cells.** As shown in Figure 1, CoNPs and Co²⁺ induced a concentration- and time-dependent reduction in the viability of Balb/3T3 cells. Whilst 10 μM Co²⁺ did not significantly affect cell viability at four hours, >50 μM Co²⁺ significantly decreased cell viability. Whereas 5 μM CoNPs had no influence on cell viability, >10 μM induced reduction of cell viability (Fig. 1a). At 48 hours, 50 μM Co²⁺ had a significant reduction of cell viability and 5 μM CoNPs induced reduction of cell viability (Fig. 1c). The inhibitory concentration 50 values at 24 hours were approximately 50 μM CoNPs and 100 μM Co²⁺, respectively (Fig. 1b). Therefore, those concentration values were used for the subsequent tests. Our results showed that pretreatment with 50 μM Zn exhibited significant protective effects on the cell viability (p < 0.05), which showed 51.36% (sd 5.09) and 67.91% (sd 6.97) increased survival respectively, compared with that in Co²⁺ and CoNPs treated cells. In addition, pretreatment with 50 μM Zn²⁺ did not show cytotoxicity and in fact an increase in cell viability was observed (Fig. 2). **ROS formation.** ROS production, plotted as a function of intracellular Co content, is shown in Figure 3. An increase of ROS formation dependent on concentration was observed in cells exposed to Co²⁺ and CoNPs. The
formation of ROS induced by CoNPs and Co\(^{2+}\) was prevented by pretreatment with 50 μM Zn in Balb/3T3 cells. **Zn inhibited inflammatory cytokines.** The results as illustrated in Figure 4 showed that the levels of TNF-α, IL-1β and IL-6 exposed to CoNPs and Co\(^{2+}\) groups were significantly raised as compared with the control group. Pretreatment of cells with 50 μM Zn provided significant protection as compared with the exposed to CoNPs and Co\(^{2+}\) groups. Specifically, Zn pretreatment reduced the level of TNF-α induced by Co\(^{2+}\) and CoNPs by 62.55% (sd 2.71) and 58.22% (sd 5.49), respectively. Zn pretreatment inhibited IL-6 level by 48.41% (sd 3.76) and 55.28% (sd 4.33) and IL-1β levels by 46.97% (sd 3.18) and 54.52% (sd 1.84), compared with that in Co\(^{2+}\) and CoNPs treated cells, respectively.

**Discussion**

Wear debris from orthopaedic patients with MOM bearing surfaces is produced by mechanical wear, surface corrosion, or both. It contains insoluble CoNPs and Co\(^{2+}\), which may lead to prosthetic failure and adverse effects. Daniel et al\(^{25}\) demonstrated that in resurfacing arthroplasty patients, mean whole blood Co and Cr concentrations were 1.26 μL/L and 2.41 μL/L at one year and 1.17 μL/L and 1.11 μL/L at six years, respectively. However, the molecular mechanisms involved in cytotoxicity induced by CoNPs and Co\(^{2+}\) remains to be elucidated. In the present study, we have focused on the mechanisms of the adverse effects and evaluated the protective effect of Zn pretreatment on CoNPs and Co\(^{2+}\) cytotoxicity on Balb/3T3 cells.

In this study, the CCK8 assay was used to assess Balb/3T3 cells viability, exposed to CoNPs and Co\(^{2+}\). The results showed concentration and time-dependent decreases in absorbance in the CoNPs and Co\(^{2+}\) groups when compared with control cells. These results correspond well with those of previous studies,\(^{1,19,26,27}\) and CoNPs were more cytotoxic than Co\(^{2+}\). It is suggested that Co\(^{2+}\) firstly saturates the binding sites of molecules in the extracellular milieu and on the cell surface, becoming unavailable to enter cells; after saturation, Co\(^{2+}\) are actively transported inside cells.\(^{28}\) The cytotoxicity of nanoparticles is likely to be mediated by the nanoparticles themselves rather than by their corrosion into ions in the culture medium.\(^{28}\)

CoNPs and Co\(^{2+}\) induced a concentration-dependent increase in ROS, as previously shown with Co oxide nanoparticles.\(^{6}\) ROS can cause DNA damage, oxidative stress and activate other cellular processes.\(^{9}\) Oxidative stress has been proposed to play a key role in the mechanism of toxicity for a number of nanoparticles, through either the excessive generation of ROS or depletion of cellular antioxidant capacity.\(^{6}\) On the one hand, ROS function as homeostatic signaling molecules that regulate cell growth, and on the other hand, as adaptation responses at physiological concentrations. However, ROS production can result in cellular injury and death at higher concentrations. In the present study, Zn\(^{2+}\) pretreatment significantly decreased ROS production compared with exposure to CoNPs and Co\(^{2+}\) alone. The cytotoxic effect of 100 μM of Co\(^{2+}\) and 50 μM CoNPs

---

**Fig. 2**

Protective effect of zinc ions (Zn\(^{2+}\)) pretreatment against cytotoxicity induced by cobalt nanoparticles (CoNPs) and cobalt ions (Co\(^{2+}\)) was measured in Balb/3T3 cells. The cells were pretreated with 50 μM Zn\(^{2+}\) for four hours and subsequently exposed to 100 μM CoNPs and 500 μM Co\(^{2+}\) for 24 hours. Cells cultured with serum-free medium served as control group. Cell viability was measured by Cell-Counting Kit 8 assay. The values were presented as means ± standard deviation from three independent experiments. *p < 0.05 compared with the CoNPs treated group. †p < 0.05 compared with control group. ‡p < 0.05 compared with the relevant treatment group.

**Fig. 3**

Relative percentage change in the production of reactive oxygen species (ROS) was measured on cobalt ions (Co\(^{2+}\)), cobalt nanoparticles (CoNPs) and zinc ions (Zn\(^{2+}\)) pretreated groups. Each value represents the mean ± standard deviation of three independent experiments, performed in triplic. *p < 0.05 compared with control group. †p < 0.05 compared with Co\(^{2+}\) treated group. ‡p < 0.05 compared with the CoNPs treated group.
were inhibited by pretreatment of cells with 50 μM Zn2+. Gürbay reported the preventive effect of Zn2+ against cytotoxicity of Co2+ and Zn deficiency increased chromium(IV)-induced cytotoxicity. It has been known that intracellular zinc levels influence cell survival. Furthermore, Zn is an essential component of numerous proteins involved in the defense against oxidative stress. Present results, along with our previous study, verify that Zn pretreatment is important for protection against Co-induced cytotoxicity.

Previous studies have shown that periprosthetic Co-Cr wear particles induced diverse pro-inflammatory cytokines release, such as IL-6, IL-1β and TNF-α. The increased pro-inflammatory responses stimulated the cell death process. This study confirms the pro-inflammatory character of Co2+ and CoNPs by an increase in TNF-α, IL-1β and IL-6. IL-1β is a component of the inflammasome and is processed by active caspase-1 cleaving the precursor IL-1β. The effects of chronic inflammation include induction of oxidative stress, while oxidative stress can induce inflammatory cytokines. Thus, there is a vicious cycle among inflammation, oxidative stress, and induction of toxic inflammatory cytokines. Zn pretreatment led to a significant decrease in the number of inflammatory cytokines induced by Co2+ and CoNPs that were released after 24 hours of exposure. Zn deficiency in diabetic patients increased cardiovascular events, which may be related to the increased inflammatory response in the renal system and vascular systems. Moreover, the generation of inflammatory cytokines is increased as a result of zinc deficiency. In the current study, we determined whether Zn pretreatment can reduce increasing inflammatory cytokines levels induced by CoNPs and Co2+. Zn uniquely functions not only as an antioxidant but also as an anti-inflammatory agent. In this study, elevated levels of IL-6, IL-1β and TNF-α in the Balb/3T3 cells exposed to 50 μM CoNPs and 100 μM Co2+ were significantly decreased by pretreatment with 50 μM Zn for four hours, which suggested that Zn can protect against inflammatory cytokines of Balb/3T3 cells induced by 50 μM CoNPs and 100 μM Co2+.

Zn has been shown to have antioxidant, anti-inflammatory and membrane-stabilising properties. Zinc's function as an antioxidant involves two different mechanisms: 1) the protection of sulphhydryl groups of proteins against free radical attack and 2) the reduction of free radical formation through the antagonism of redox-active transition metals, such as iron and copper. Evidence shows that cellular oxidative stress is markedly induced by exposure to linoleic acid and that this oxidative stress can be partially blocked by Zn. Research indicates that Zn is a potent inhibitor of apoptosis and that Zn deficiency can induce apoptosis. Recently, it was reported that the protective effects of Zn may occur through inhibition of caspases, such as caspase-3, and metholithionein (MT) expression. MT is a cysteine-rich metal-binding protein that has several biological roles including antioxidant properties. It is shown that Co can displace intracellular Zn2+ in cells exposed to Co2+ and CoNPs, which decreases the intracellular Zn2+ level. Thus, the replacement of essential divalent cations might contribute to the cytotoxicity induced by Co particles.

In the present study, we showed that Co2+ and CoNPs had concentration- and time-dependent cytotoxicity in Balb/3T3 cells, and that Zn pretreatment could reduce
the cytotoxicity, ROS production, and levels of TNF-α, IL-1β, and IL-6, which suggested that Zn^{2+} pretreatment has a protective effect. Our study provided a new insight into the roles of Zn pretreatment in ameliorating cytotoxicity and aseptic inflammation induced by CoNPs and CoO^{2+}. Further research into the functional roles of Zn and metal ions in tissue damage due to MOM arthroplasty corrosion should focus on mitigating the toxic effects of these processes.
