Abstract

A new, exactly solvable, Barbieri-Remiddi like equation for bound states of two scalar constituents interacting with massless vector particles is presented, both for stable and unstable particles. With the help of this equation the bound state spectrum is calculated to $O(\alpha^4)$ for a SU(N) nonabelian gauge theory. The result for the abelian case reproduces the known result from the Foldy-Wouthuysen calculation. It is shown how different graphs as in the fermionic theory contribute to the spectrum to this order. Furthermore the bound state correction to the decay width for a weakly decaying system is calculated. This result is equal to its fermionic counterpart. Thus the theorem on bound state corrections for weakly decaying particles, formulated previously for fermions only, has been extended to the scalar theory.

revised version, Wien, Dec. 1996

1 Introduction

While the discussion of fermionic bound states has a long history [1], much less attention has been paid to the similar problem with scalar constituents. Only the ladder approximation with scalar interaction is a well known example and has already been discussed in the 50-s and 60-s [2] in the framework of the Bethe-Salpeter equation. Indeed, to this day the only known fundamental matter fields are fermionic. But in supersymmetric theories for each fermion two scalar partners are required. Since some of them, probably stop or sbottom, could have masses within the reach of the next generation of $e^+e^-$ accelerators, even the observation of bound states of those particles seems possible. These objects and systems built of scalar composite particles in atomic physics underline the need of an equally clear and transparent approach as the one developed for the fermionic case [3].

A recent attempt in this direction [4] splits the boson propagator in a particle and anti-particle propagator in order to be able to treat them like fermions. The spectrum is then obtained by constructing the Hamiltonian via a Foldy-Wouthuysen transformation and a perturbation theory à la Salpeter. This approach does not show significat advantage over the pure Foldy-Wouthuysen approach [5] and suffers also from the drawback that it will break down in higher orders due to the appearance of higher powers in the spatial momentum $\vec{p}$. The Coulomb field appears in this formalism as an external field which makes this formalism not very reliable-looking. All these drawbacks can be circumvented by developing an exactly solvable zero order equation and subsequently using a systematic perturbation theory.

To the best of our knowledge there exists no attempt in the literature to construct a solvable zero order equation for the BS equation containing two charged scalars interacting via a vector field. This goal will be achieved in section 2.

In section 3 we will review briefly the BS perturbation theory and use it to calculate the spectrum of bound states for scalar particles with equal mass, both for the abelian and

1
nonabelian case to $O(\alpha^4)$. This will be of importance if the stop has a narrow width. If the width becomes comparable to the level splittings this considerations can be understood as a determination of the scalar-antiscalar potential.

The decay width is also subject of the second application we present in section 4. We calculate the bound state correction to the decay width $\Gamma$ of system of scalar constituents to $O(\alpha^2\Gamma)$.

Finally section 5 is devoted to the conclusions and to the discussion of our results.

2 A bound state equation for scalar particles

2.1 Stable particles

As starting point we present here an exactly solvable equation for stable scalar particles which interact via a vector field.

We start from the BS equation for a bound state wave function $\chi$

\[
\chi_{ij}^{BS}(p; P) = -iS_{ii'}\left(\frac{P}{2} + p\right)S_{jj'}\left(-\frac{P}{2} + p\right)\int \frac{d^4p'}{(2\pi)^4} K_{i'i',\nu\nu'}(P, p, p')\chi_{i'j'}^{BS}(p'; P),
\]

where $S$ is the exact scalar propagator, and $K$ is the sum of all two scalar irreducible graphs. Both are normalized to be Feynman amplitudes. Furthermore, we have introduced relative momenta $p$ and $p'$, a total momentum $P = p_1 - p_2$, and we choose the center of mass (CM) frame where $P = (P_0, \vec{0}) = (2m + E, \vec{0})$.

As a first approximation to eq. (1) we would like to use beside the free relativistic scalar propagators the kernel due to the Coulomb interaction

\[
K_C(p, p') = 4\pi\alpha \frac{(P_0 + p_0 + p'_0)(P_0 - p_0 - p'_0)}{(p - p')^2}.
\]

For a nonablelian theory with gauge group $SU(N)$ we use

\[
\alpha = \frac{N^2 - 1}{2N} \frac{g^2}{4\pi}.
\]
In this case $\chi$ has to be a singlet in order that $K_C$ represents an attractive force. The kernel (2) has the drawback that it is $p_0$ dependent and the exact solution of eq. (1) with (2) is not known. However, in the nonrelativistic regime by the scaling argument [6]

$$p_0 \approx O(\alpha^2 m), \quad \vec{p} \approx O(\alpha)$$

we can start with an instantaneous approximation to the kernel since $p_0$ is of $O(\alpha^2 m)$ in this region and may be included in the corrections afterwards. Doing this, we can perform the zero component integration on the propagator ($E_p = \sqrt{m^2 + \vec{p}^2}$)

$$-i \int \frac{dp_0}{2\pi} \frac{1}{[(E_p/2 + p_0)^2 - E_p^2 + i\epsilon][(-E_p/2 + p_0)^2 - E_p^2 + i\epsilon]} = \frac{1}{2E_p P_0} \left[ \frac{1}{2E_p - P_0} - \frac{1}{2E_p + P_0} \right] = \frac{1}{E_p(4E_p^2 - P_0^2)}$$

and it is quite easy to show that

$$K_0(p, p') = 4\pi \frac{4m \sqrt{E_p E_{p'}}}{q^2}$$

gives a solvable equation with the normalized solutions

$$\chi(p) = i \frac{\sqrt{E_p(P_0^2 - 4E_p^2)}}{\sqrt{2P_0[(E_p/2 + p_0)^2 - E_p^2 + i\epsilon][(-E_p/2 + p_0)^2 - E_p^2 + i\epsilon]}} \phi(p)$$

$$\bar{\chi}(p, \epsilon) = -\chi^*(p, -\epsilon)$$

to the eigenvalues

$$P_0 = M_n^{(0)} = 2m \sqrt{1 - \sigma_n^2}, \quad \sigma_n = \frac{\alpha}{2n}.$$  \hfill (9)

Eq. (8) is dictated by the requirement that $\bar{\chi}$ should acquire the same analytic properties as the underlying field correlators

$$\chi(p) = \int e^{ipx} \langle 0|T\Phi^i(\frac{x}{2})\Phi(-\frac{x}{2})|P_n \rangle,$$

$$\bar{\chi}(p) = \int e^{-ipx} \langle P_n|T\Phi^i(\frac{x}{2})\Phi^i(-\frac{x}{2})|0 \rangle.$$  \hfill (11)
Using the integral representation for the step function which is included in the time ordered product, one derives eq. (8).

Taking the equation for the Green function

$$iG_0 = -D_0 + D_0K_0G_0,$$

with

$$D_0 = \frac{(2\pi)^4\delta^4(p - p')}{[(\frac{\hbar}{2} + p_0)^2 - E^2_p + i\epsilon][(-\frac{\hbar}{2} + p_0)^2 - E^2_p + i\epsilon]},$$

instead of that for the BS wave function and using again (8) we find

$$G_0 = -F(p)\frac{G_C(\hat{E}, \vec{p}, \vec{p}')}{4m}F(p'),$$

with

$$\hat{E} = \frac{P_0^2 - 4m^2}{4m}$$

and

$$F(p) = \frac{\sqrt{E_p(P_0^2 - 4E_p^2)}}{[(\frac{\hbar}{2} + p_0)^2 - E^2_p + i\epsilon][(-\frac{\hbar}{2} + p_0)^2 - E^2_p + i\epsilon]}.$$

$G_C$ denotes the well known Coulomb Green function in momentum space. These solutions can be used for a systematic BS perturbation theory for scalar constituents, as will be demonstrated in the next section.

### 2.2 Unstable Particles

As has been shown recently by the author [7] for the fermionic case, an important simplification can be achieved in some calculations if the width of the bound state is already included in the zero order equation. Furthermore, if the width becomes comparable to the level shifts, this approach even becomes indispensible. For the scalar case this can be done by the replacement

$$E_p \rightarrow \sqrt{E^2_p - i\Gamma m}.$$
While (17) leads to expressions for the BS wave functions which contain unpleasant expressions for the particle poles it has the advantage that the propagator has the form as expected from the phase space of an unstable particle. Furthermore the above calculation remains essentially unchanged if we define the square root in (17) to be that with the negative imaginary part (clearly we demand $\Gamma > 0$ and $m > 0$). Only the energy in the resulting equation for the Green function and thus in (14) changes to

$$\hat{E} = \frac{P_0^2 - 4m^2}{4m} + i\Gamma.$$  

(18)

The eigenvalues for $P_0$ are

$$P_{0,n} = 2m\sqrt{1 - \sigma_n^2 - \frac{i\Gamma}{m}} \approx 2m - m\sigma_n^2 - \frac{m\sigma_n^4}{4} + \frac{\Gamma^2}{4m} - i\Gamma - i\frac{\sigma_n^2\Gamma}{2}.$$  

(19)

In the case of the fermions we managed to construct wave functions independent of $\Gamma$. This was possible because the small components of the propagator containing $P_0 - i\Gamma$ instead of $P_0 + i\Gamma$ were projected away by the choice of an appropriate kernel $K$. This cannot be achieved in the scalar case and thus, surprisingly enough, the scalar wave functions look more complicated than the fermionic ones. A version for a zero order equation for decaying particles where the propagator is chosen in close analogy to the fermionic case has been developed in [8]. In our present work we, instead, proceed in the spirit of our generalized approach.

### 3 Perturbation Theory

Perturbation theory for the BS equation starts from the BR equation for the Green function $G_0$ (eq. (12)) of the scattering of two fermions [9] which is exactly solvable. $D_0$ is the product of two zero order propagators, $K_0$ the corresponding kernel. The exact Green function $G$ may be represented as

$$G = \sum_{l} \chi_{nl}^{BS} \frac{1}{P_0 - P_n} \chi_{nl}^{BS} + G_{reg} = G_0 \sum_{\nu=0}^{\infty} (HG_0)^\nu,$$  

(20)
where the corrections are contained in the insertions $H$ and $G_{reg}$ is the part of $G$ regular at $P_0 = P_n$. It is easy to show that $H$ can be expressed by the full kernel $K$ and the full propagators $D$:

$$H = -K + K_0 + iD^{-1} - iD_0^{-1}. \quad (21)$$

Thus the perturbation kernel is essentially the negative difference of the exact BS-kernel and of the zero order approximation.

Expanding both sides of equation (21) in powers of $P_0 - P_n$, the mass shift is obtained [6, 10]:

$$\Delta M - i \frac{\Delta \Gamma}{2} = \langle h_0 \rangle (1 + \langle h_1 \rangle) + \langle h_0 g_1 h_0 \rangle + O(h^3). \quad (22)$$

Here the BS-expectation values are defined as e.g.

$$\langle \langle h \rangle \rangle \equiv \int \frac{d^4 p}{(2\pi)^4} \int \frac{d^4 p'}{(2\pi)^4} \chi_{ij}(p) h_{ii'}(p, p') \chi_{j'j}(p'), \quad (23)$$

We emphasize the four-dimensional $p$-integrations which correspond to the generic case, rather than the usual three dimensional ones in a completely nonrelativistic expansion. We distinguish these two cases by introducing the notation $\langle \langle ... \rangle \rangle$ for a four-dimensional expectation value and $\langle ... \rangle$ for the usual nonrelativistic expectation value

$$\langle V(\vec{p}, \vec{p}') \rangle = \int \frac{d^3 p}{(2\pi)^3} \int \frac{d^3 p'}{(2\pi)^3} \phi^*(\vec{p}') V(\vec{p}, \vec{p}') \phi(\vec{p}) \quad (24)$$

Of course, (23) reduces to an ordinary ”expectation value” involving $d^3 p$ and $\Phi(\vec{p})$, whenever $h$ does not depend on $p_0$ and $p'_0$.

In (22) $h_i$ and $g_i$ represent the expansion coefficients of $H$ and $G_0$ near the pole at $P_n$, respectively, i.e.

$$H = \sum_{m=0}^{\infty} h_m (P_0 - P_n)^m \quad (25)$$

$$G_0 = \sum_{m=0}^{\infty} g_m (P_0 - P_n)^{m-1} \quad (26)$$

Similar corrections arise for the wave functions [6, 10]:

$$\chi^{(1)} = (g_1 h_0 + \frac{1}{2} \langle h_1 \rangle) \chi^{(0)}. \quad (27)$$
3.1 Fine structure

As an application of this perturbation theory as well as of the new zero order equation for scalar particles developed in the last section, we will present here the calculation of the fine structure of two stable scalar particles interacting via a vector particle. Existing calculations [4] rely on a mix of Fouldy-Wouthuysen transformation and the iterated Salpeter perturbation theory. Our present approach is much more transparent and allows in principle the inclusion of any higher order effect in a straightforward manner. First we will calculate the fine structure for two scalars of equal mass interacting by an abelian vector field. Then we consider also the nonabelian case which could be of interest for the stop-antistop system. In this case we will calculate the spectrum up to order $\alpha_s^4$.

Since in the zero order equation we have replaced the exact one Coulomb exchange (2) by $K_0$ as given in (3) we have now to calculate the contribution of $-K_C + K_0$ to the energy levels. This is shown in fig. (1)a. With

$$\langle\langle -K_C \rangle\rangle = -4\pi\alpha \int \frac{d^4p}{(2\pi)^4} \frac{d^4p'}{(2\pi)^4} \chi(p) (p_0 + p_0') (p_0 - p_0') \chi(p') =$$

$$= -\frac{P_0^2 + 2E_p^2 + 2E_{p'}^2}{4P_0 \sqrt{E_p E_{p'}}} \frac{4\pi\alpha}{q^2} =$$

$$= -\left( \frac{2m}{P_0} - \frac{\sigma^2}{2} \right) \frac{4\pi\alpha}{q^2}$$

$$\langle\langle K_0 \rangle\rangle = \frac{2m}{P_0} \langle \frac{4\pi\alpha}{q^2} \rangle$$

we obtain

$$\Delta M_C := \langle\langle -K_C + K_0 \rangle\rangle = \frac{\sigma^2}{2} \langle \frac{4\pi\alpha}{q^2} \rangle = \frac{m\alpha^4}{16n^4}.$$  (30)

The fact that the p-integrations are well behaved and the result is of $O(\alpha^4)$ proves the usefulness of our zero order kernel.

The transverse gluon of fig. (1)b gives rise to a kernel

$$H_T = \frac{4\pi\alpha}{q^2} \left( (p + p')^2 - \frac{(p^2 - p'^2)^2}{q^2} \right)$$

(31)
Performing the zero component integrations exactly and expanding in terms of the spatial momenta one obtains to leading order (c.f. [11])

\[ \Delta M_T = \langle \langle H_T \rangle \rangle = -4\pi \alpha \frac{\vec{p}^2}{m^2} \frac{\langle \vec{q} \rangle^2}{\vec{q}^2} \]

\[ = m\alpha^4 \left( \frac{1}{8n^4} + \frac{\delta}{8n^3} - \frac{3}{16n^3(l + \frac{1}{2})} \right) . \]

Due to the fact that scalars can only form spin zero bound states, the the annihilation graph into one gauge particle (with spin one) contributes only for p-waves and thus is suppressed by two additional powers in \( \alpha \). Furthermore, as in the fermionic case, it vanishes for the nonabelian theory due to the color trace since the bound states are color singlets.

As can be seen from the above results the contribution of the transverse gauge field is equal for fermions and bosons. However, the relativistic correction to the Coulomb exchange appears to be different. Let us therefore check the contribution of this Coulomb correction from second order perturbation theory (fig. 2.a). These contributions give only rise to \( O(\alpha^5 \ln \alpha) \) effects in the fermionic theory. Since the leading Coulomb singularity is cancelled we may hope that we can replace the Green function by the free propagator.
Indeed it can be shown that the next terms of the Green function give only higher order contributions.

Due to the presence of the zero component momentum in the scalar-Coulomb gluon vertex we observe that the contribution from fig. 2b diverges linearly. However, it is an easy exercise to show that in the sum of graphs (fig. 2b + fig. 3) this linear divergence cancels. Thus we regularise all the single graphs, sum up and find a finite result. We have used dimensional regularization as well as a one dimensional Pauli-Villars regularization. Both give the same result for the finite parts of the integrals.

\[
\Delta M_{\text{box}} = \langle \langle h_0^{(3)} \rangle \rangle + \langle \langle (-K_C + K_0) g_1(-K_C + K_0) \rangle \rangle
\]

(34)

\[
\langle \langle h_0 \rangle \rangle = \langle \langle -i \int \frac{d^3k}{(2\pi)^3} \frac{I_0}{k_2 (q - k)^2} \rangle \rangle
\]

(35)

where \( I_0 \) is decomposed according to fig. 3 for a generic \( SU(N) \) theory:
\[ I_0^{(3.a)} = \frac{C_F}{2N} \int_{k_0} \frac{(P + 2p' + k_0)(-P + 2p' + k_0)(P + p + p' - k_0)(P + 2p - k_0)}{[(\frac{P}{2} + p - k)^2 - m^2][(-\frac{P}{2} + p' + k)^2 - m^2]} = \]
\[ \approx \frac{C_F}{2N} (\frac{\Lambda}{2} - 2im) \] (36)
\[ I_0^{(3.b)} = (C_F^2 - \frac{C_F}{2N}) \int_{k_0} \left( \frac{(P + p + p' - k_0)(P + 2p - k_0)}{[(\frac{P}{2} + p - k)^2 - m^2]} + \frac{(-P + 2p' + k_0)(-P + p + p' + k_0)}{[(-\frac{P}{2} + p' + k)^2 - m^2]} \right) = \]
\[ \approx 2(C_F^2 - \frac{C_F}{2N})(\frac{\Lambda}{2} - im) \] (37)
\[ I_0^{(3.c)} = -(C_F^2 - \frac{C_F}{2N}) \int_{k_0} = \]
\[ = -(C_F^2 - \frac{C_F}{2N})(\frac{\Lambda}{2}) \] (38)

Using the abbreviations
\[ \int_{k_0} = \int \frac{dk_0}{2\pi} \frac{\Lambda^2}{k_0^2 + \Lambda^2} \quad (39) \]
\[ C_F = \frac{N^2 - 1}{2N} \quad (40) \]

we have written the result for Pauli Villars regularization to make the cancellation of the linear divergent parts obvious.

For the double Coulomb exchange graph from fig. 3 we obtain for the time component integral
\[ I_0^{(2.b)} = -C_F^2 \int_{k_0} \frac{[(p_0' + k_0)^2 - P^2 - 4m\sqrt{E_kE_{p'}}][(p_0 + k_0)^2 - P^2 + 4m\sqrt{E_kE_{p'}}]}{[(\frac{P}{2} + k_0)^2 - E_k^2][(\frac{P}{2} + k_0)^2 - E_k^2]} = \]
\[ = -C_F^2 (\frac{\Lambda}{2} - im) \] (41)
Collecting everything from above we have

$$I_0 = I_0^{(3,a)} + I_0^{(3,b)} + I_0^{(3,c)} + I_0^{(2,b)} = -C_F i m,$$  \hspace{1cm} (42)

which leads with eq. (35),(40) and (3) immediately to the result

$$\Delta M_{abelianbox} = -\frac{m\alpha^4}{16n^3(l + \frac{1}{2})},$$  \hspace{1cm} (43)

The net result for the spectrum of two scalars bound by an abelian gauge field is equal to that of ref [4]. However, we showed which graphs contribute in a pure BS approach which can be used as a basis for any higher order calculation.

We have also checked the derivative $\partial K_0/\partial P_0$ contributing to $h_1$ and the X-graphs of fig. (4.g) with transverse gauge particles for possible contributions. Our estimates only yield contributions to higher order. Due to mass and wave function renormalization we can further assume that the graphs of fig. (4.e,f) give only contributions to $O(\alpha^5 \ln \alpha)$ as in the fermionic case [12]. Possible large contributions of lighter particles to the vacuum polarization as depicted in (4.c) can be treated as in the fermionic case [13].

In supersymmetric theories a $|\Phi|^4$ term is part of the lagrangian. Clearly it can be put in by hand into the Langragian of an ordinary quantum field theory. The contribution from an interaction term of the form $-\lambda/2(\Phi^\dagger T^a \Phi)(\Phi^\dagger T^a \Phi)$ is easily calculated:

$$\Delta M_X = -C_F \lambda \frac{m\alpha^3}{32\pi n^3} \delta_{10},$$  \hspace{1cm} (44)

and gives a contribution of the same form as the Darwin term (usually interpreted as a zitterbewegung contribution) which is suppressed by two orders in $\alpha$ in the scalar theory. There may exist a small chance that this term may be helpful for the determination of the supersymmetry parameters of the theory contained in $\lambda$.

For an ordinary quantum field theory without a direct interaction on the tree level it was shown first by Rohrlich [14] that a counter term of this form is needed for the scattering of two scalars (e.g the graphs of fig. 3 and the first of fig. 2.b with Photons in
Feynman gauge. It is interesting to note that in Coulomb gauge the divergencies for the Coulomb photons cancel and the only divergent graph is the one of fig. 3.c with transverse photons.

The spectrum calculated so far is common for the abelian and the nonabelian theory. Collecting all pieces a we have

$$
\Delta M = \Delta M_{F,nl}^j + \frac{m\alpha^4}{8} \left( \frac{5}{4n^4} + \frac{\delta l_0}{n^3} \left( 1 - \frac{C_F \lambda}{4\pi \alpha} \right) - \frac{4}{n^3(l + \frac{1}{2})} \right)
$$

(45)

where $\Delta M_{F,nl}^j$ originates in the contribution of $j$ light fermions to the vacuum polarization and can be found in [13].

It has been pointed out first in [15] that in the case of a nonabelian gauge field further corrections may arise due to the gluon splitting vertices. The $O(\alpha^3)$ corrections from fig. (4.a, b) as well as the $O(\alpha^4)$ corrections from the corresponding two loop graphs are obviously the same as in the fermionic case. The vertex correction shown below in fig. (4.d) has been calculated in [15] for the fermionic case.

Here we will give a calculation of the same contribution for scalar constituents. After performing the color trace the perturbation kernel for the second graph in fig. (4.d) reads

$$
H_{4,d,2} = -8ig^4 \int \frac{d^4k}{(2\pi)^4} \frac{(P_0 + p_0 + p'_0 - k_0)(-P_0 + p_0 + p'_0)}{(q^2)^2((\frac{L}{2} + p + k)^2 - m^2)k^2} \left( -\frac{\bar{q}q}{k^2} + \frac{(\bar{p}k)(\bar{q}k)}{k^2} \right).
$$

(46)

Performing the $k_0$ integration and using the scaling

$$
P_0 \to 2m + O(\alpha^2)$$

$$p_0 \to \alpha^2 p_0$$

$$\vec{k} \to \alpha \vec{k}$$

to extract the leading contribution in $\alpha$ we find that

$$
H_{4,d,2} = -\frac{g^2 m}{2} \frac{\bar{p}q}{|q|^3}.
$$

(47)
Adding the similar contribution from the first graph in fig. (4.d) gives

\[ H_{4.d} = -\frac{9\pi^2\alpha^2 m}{|q|}. \]  

(48)

This result differs by a factor 4\(m^2\) from the fermionic result which is compensated by a corresponding difference in the wave functions to give eventually precisely the same result as in the fermionic case

\[ \Delta M = \left\langle \frac{9\pi^2\alpha^2}{4m|q|} \right\rangle = \frac{9m\alpha^4}{32n^3(l + \frac{1}{2})}. \]  

(49)

In view of the fact that the result depends only on the angular momentum and not on the spin this seems reasonable. However, we have seen in the case of the Darwin term this kind of reasoning sometimes fails.

Proceeding to the graph of fig. (4.h) we observe that in contrast to the fermionic case the zero component integration develops Coulomb divergencies like the abelian contributions. Since this integrations are a little bit cumbersome in dimensional regularization we sketch the calculation in the appendix. It turns out finally that the box graph contribution in fig. (4.h) gives the same result as in the fermionic case, which was calculated recently [16].

\[ \langle\langle H_{(4,h)}\rangle\rangle = \frac{81}{128}\pi(12 - \pi^2)\left(\frac{\alpha^3}{q^2}\right). \]  

(50)

The box graph with two Coulomb lines crossed, vanishes due to the color trace. Another box graph with the Coulomb vertices on one scalar line replaced by a seagull vertex can be shown to contribute to \(O(\alpha^5)\). However, they are in principle needed to cancel the Coulomb singularities.

Thus the difference in the spectrum of the scalar bound state to \(O(\alpha^4)\) compared to the fermionic case is entirely due to the graphs also present in the abelian theory discussed above.
4 Bound state corrections to the decay width

Assuming that the scalar particle under consideration decays into two other particles, the decay width is the imaginary part of the self energy function $\Sigma$ at the mass shell. Focusing on the stop quark a possible scenario could be $\tilde{t}_R \rightarrow b + \tilde{\chi}_i$ [17]. We shall be interested in terms of the order $O(\alpha^2 \Gamma)$ where $\Gamma$ is the tree level decay width. The first part of the perturbation kernel due to the exact inverse propagator $p^2 - m^2 - \Sigma(p^2)$ for the bound state corrections to the decay width reads

$$H_1 = iD^{-1} - iD_0^{-1} =$$
\[
\approx -2i(2\pi)^4\delta^4(p_1 - p_2)\Sigma'(m^2)(p_1^2 - m^2)(p_2^2 - m^2)
\]  

(51)

In the derivation of eq. (51) we expanded the self energy function around the mass shell

\[
\Sigma(p^2) = \Sigma(m^2) + \Sigma'(m^2)(p^2 - m^2) + O((p^2 - m^2)^2)
\]  

(52)

and we assumed that the decay width used in the zero order equation (e.g. in \(D_0\)) is given by

\[
\Gamma = -\text{Im}\frac{\Sigma(m^2)}{m}.
\]  

(53)

As has been first shown in [18], the gauge dependence contained in the off shell contribution \(\Sigma'\) is cancelled by parts of the vertex correction depicted in fig. 4.f. It gives rise to a perturbation kernel

\[
H_2 = \Lambda_0 \frac{4\pi\alpha}{q^2}(-P_0 + p_0 + p_0'),
\]  

(54)

with \(\Lambda_0\) representing the vertex correction. The color trace is already included in \(\alpha\). As in the fermionic case [7] it is possible to derive a Ward identity which guarantees the cancellation of the gauge dependent terms (the \(T^a\)'s are the \(SU(N)\) generators)

\[
\Lambda^a_{\mu}(p, q = 0) = -2gT^a p_\mu \frac{\partial}{\partial p^2} \Sigma(p^2),
\]

\[
\text{Im}\Lambda_0(p = (m, \vec{0}), q = 0) = -2m\text{Im}\Sigma'(m^2).
\]  

(55)

But the detailed calculation shows differences to the fermionic case: The sum of the contributions from \(H_1\) and \(H_2\) vanishes to the desired order with the help of the zero order equation

\[
\text{Im}\langle\langle H_1 + H_2\rangle\rangle \approx 0.
\]  

(56)

On the other hand, we observed above that the wave functions for decaying fermions and scalars were very different. While it was possible to obtain the same wave functions for decaying fermions and for stable ones, in the bosonic case we used wave functions explicitely containing the decay width (cf. sect. 2.2). Thus we have to reexamine the relativistic corrections to the energy levels. Among the contributions considered in the
last section only the relativistic Coulomb correction fig. 1.a can produce corrections to $O(\alpha^2 \Gamma)$.

It is easy to see that the only difference comes from the fact that the perturbation has to be taken at the position of the pole (19) which leads to the replacement

$$\sigma_n^2 \rightarrow \sigma_n^2 + \frac{i \Gamma}{m}.$$  

in eq. (28). We thus get a relativistic correction to the decay width of the bound state

$$\Delta \Gamma_{1,a} = -\frac{\Gamma \alpha^2}{2n^2}.$$  

This has to be added to the $O(\alpha^2 \Gamma)$ term of (19) to yield the final result for the boundstate correction to the decay width:

$$\Delta \Gamma = -\frac{\Gamma \alpha^2}{4n^2}.$$  

This result generalizes the result of [7, 18] to the bosonic case. We can thus say that the effect of the bound state corrections to the decay width can be interpreted entirely as a time dilatation effect as was first conjectured for the fermionic theory [13].

5 Conclusion

We have presented a consistent formalism for the calculation of bound state properties for scalar particles interaction with an abelian or nonabelian spin one vector field. This is done by deriving a solvable relativistic zero order equation similar to that of Barbieri and Remiddi both for stabel and unstable scalars. Based on this equation a systematic perturbation theoy can be built which allows especially the calculation of the position of the bound state poles to higher orders.

Using this approach the bound state spectrum was calculated to $O(\alpha^4)$. We found that we had to take into account the abelian box graphs to this order. This is not the case in the fermionic theory. All the relativistic Coulomb corrections only reproduce the
\( \vec{p}^4 \) term from the expansion of \( \sqrt{m^2 + \vec{p}^2} \) indicating that a fully relativistic formulation is not really economic for the lowest orders in perturbation theory. However, the advantage of the presented formalism is that it is straightforward applicable to any higher order calculation. We calculated also the nonabelian contributions to \( O(\alpha^4) \). Furthermore our approach makes possible the calculation of the bound state corrections to the decay width of weakly decaying scalar particles. We show that - as in the fermionic case - the inclusion of a finite, constant decay width in the zero order equation simplifies the problem of the bound state correction to the decay width in a profound way. It is now possible to clearly isolate the underlying cancellation mechanism which automatically gives a gauge independent result which can be interpreted as time dilatation alone. We can thus generalize the theorem on the bound state corrections for the decay width to the scalar case: The leading bound state corrections for weakly bound systems of unstable scalars (with decays like \( \tilde{t}_R \rightarrow b + \tilde{\chi}_i \)) are always of the form (58).

It would be very interesting to observe a particle where the above mentioned predictions could be tested. Today it seems that the stop-antistop system could be a candidate. It will be heavy enough to allow a perturbative treatment even for the nonabelian case. Whether the decay width will be small enough to allow a detailed study of the spectrum remains open to speculation at present. But even for a quite large decay width the scalar-scalar potential will provide the basis for interesting threshold calculations for this case [20], analogous to the ones for the top-antitop system [19, 21].

**Acknowledgement**: I would like to thank Prof. W. Kummer for helpful discussions and a careful reading of the manuscript. Furthermore I am grateful to D. Raunikar and L. Widhalm for pointing out to me an error in the calculation of the abelian box graphs and for checking large parts of the calculations.
A Zero component integrations for the nonabelian box graph

The diagram 4.h leads to the energy component integrals

\[ I_0 := \int \frac{dk_0}{2\pi} \int \frac{dt_0}{2\pi} \frac{(P_0 + 2p_0 - t_0)(P_0 + 2p_0 - q_0 - t_0)(-P_0 + 2p_0 - q_0 - k_0)(-P_0 + 2p_0 - k_0)}{((P_0/2 + p_0 - t_0)^2 - E_{\vec{p}-\vec{t}}^2)\left((-P_0/2 + p_0 - k_0)^2 - E_{\vec{p}-\vec{k}}^2\right) \left((t_0 - k_0)^2 - (\vec{t} - \vec{k})^2\right)} \]  

(60)

This integral is power counting logarithmic divergent, but it turns out that the first integration is finite which leads to a linear divergent second integration. After scaling eq. (60) reduces to

\[ I_0 = -\int \frac{dk_0}{2\pi} \int \frac{dt_0}{2\pi} \frac{(2m - t_0)(2m + k_0)}{(t_0 - i\epsilon)(k_0 + i\epsilon)(t_0 - k_0)^2 - (\vec{t} - \vec{k})^2 + i\epsilon} \]  

(61)

To make this integral accessible for the methods of dimensional regularisation we use the following trick

\[ \int \frac{dt_0}{2\pi} \frac{1}{t_0 \pm i\epsilon} = \lim_{\mu \to 0} \int \frac{dt_0}{2\pi} \frac{t_0 + \mu}{t_0 - \mu^2 + i\epsilon}. \]  

(62)

Performing first the \( t_0 \) integration we have

\[
I_0 = I_{0,1} + I_{0,2} \\
I_{0,1} = \int \frac{dk_0}{2\pi} \frac{(2m + k_0)(k_0 + \mu)I_{t_0}}{k_0^2 - \mu^2 + i\epsilon} \\
I_{0,2} = \int \frac{dk_0}{2\pi} I_{t_0} \\
I_{t_0} = -\frac{2mi\Gamma(2 - \frac{D}{2})}{(4\pi)^{\frac{D}{2}}} \int_0^1 dx \frac{(xk_0 - \mu)[x(1 - x)]^{\frac{D}{2} - 2} - i\Gamma(1 - \frac{D}{2})}{[-k_0^2 + \frac{\mu^2}{x} + |\vec{t} - \vec{k}|^2 - \frac{D}{2}] (4\pi)^{\frac{D}{2}} |\vec{t} - \vec{k}|^{D-2}}
\]

The limit \( \mu \to 0 \) has to be performed very carefully to obtain

\[
I_{0,1} = \frac{2m^2}{|\vec{t} - \vec{k}|^2} - \frac{m}{2|\vec{t} - \vec{k}|} \\
I_{0,2} = -\frac{m}{2|\vec{t} - \vec{k}|}
\]  

(63)
Thus we have to the desired accuracy

\[ I_0 = \frac{2m^2}{|\vec{t} - \vec{k}|^2}. \quad (64) \]

It should be noted that dimensional regularization does not show up linear divergencies. Instead the use of the regularization (39) leads to a visible liner divergent term (of higher order in \( \alpha \)) \( i\Lambda/(8|\vec{t} - \vec{k}|) \) which has to be cancelled by similar contributions from graphs where the two Coulomb gluon vertices on one or both scalar lines are double Coulomb vertices.
