STOCHASTIC COMPLETENESS AND GRADIENT REPRESENTATIONS FOR SUB-RIEMANNIAN MANIFOLDS

ERLEND GRONG AND ANTON THALMAIER

Abstract. Given a second order partial differential operator \( L \) satisfying the strong Hörmander condition with corresponding heat semigroup \( P_t \), we give two different stochastic representations of \( dP_t f \) for a bounded smooth function \( f \). We show that the first identity can be used to prove infinite lifetime of a diffusion of \( \frac{1}{2} L_{1/2} \), while the second one is used to find an explicit pointwise bound for the horizontal gradient on a Carnot group. In both cases, the underlying idea is to consider the interplay between sub-Riemannian geometry and connections compatible with this geometry.

1. Introduction

A Brownian motion on a Riemannian manifold \((M, g)\) is a diffusion process with infinitesimal generator equal to one-half of the Laplace-Beltrami operator \( \Delta_g \) on \( M \). If \((M, g)\) is a complete Riemannian manifold, a lower bound for the Ricci curvature is a sufficient condition for Brownian motion to have infinite lifetime \([44]\). Stated in terms of the minimal heat kernel \( p_t(x, y) \) to \( \frac{1}{2} \Delta_g \), this means that \( \int_M p_t(x, y) \, d\mu(y) = 1 \) for any \((t, x) \in (0, \infty) \times M\), where \( \mu = \mu_g \) is the Riemann volume density. Infinite lifetime of the Brownian motion is equivalent to uniqueness of solutions to the heat equation in \( L_1 \), see e.g. \([22], [26, Section 5]\). Furthermore, let \( P_t \) denote the minimal heat semigroup of \( \frac{1}{2} \Delta_g \) and let \( \nabla f \) denote the gradient of a smooth function with respect to \( g \). Then a lower Ricci bound also guarantees that \( t \mapsto \|\nabla P_t f\|_{L_\infty(g)} \) is bounded on any finite interval whenever \( \nabla f \) is bounded. This fact allows one to use the \( \Gamma_2 \)-calculus of Bakry-Émery, see e.g. \([4, 5]\).

For any second order partial differential operator \( L \) on \( M \), let \( \sigma(L) \in \Gamma(\text{Sym}^2 TM) \) denote its symbol, i.e. the symmetric, bilinear tensor on the cotangent bundle \( T^* M \) uniquely determined by the relation

\[
\sigma(L)(df, d\phi) = \frac{1}{2} (L(f\phi) - fL\phi - \phi Lf), \quad f, \phi \in C^\infty(M).
\]

If \( L \) is elliptic, then \( \sigma(L) \) coincides with the cometric \( g^* \) of some Riemannian metric \( g \) and \( L \) can be written as \( L = \Delta_g + Z \) for some vector field \( Z \). Hence, we can use the geometry of \( g \) along with the vector field \( Z \) to study the properties of the heat flow of \( L \), see e.g. \([43]\). If \( \sigma(L) \) is only positive semi-definite we can still associate a geometric structure known as a sub-Riemannian structure. Recently, several results have appeared linking sub-Riemannian geometric invariants to properties of...
diffusions of corresponding second order operators and their heat semigroup, see [7, 9, 11, 23, 24]. These results are based on a generalization of the $\Gamma_2$-calculus for sub-Riemannian manifolds, first introduced in [10]. As in the Riemannian case, the preliminary requirements for using this $\Gamma_2$-calculus is that the diffusion of $L$ has infinite lifetime and that the gradient of a function does not become unbounded under the application of the heat semigroup.

Consider the following example of an operator $L$ with positive semi-definite symbol. Let $(M, g)$ be a complete Riemannian manifold with a foliation $F$ corresponding to an integrable distribution $V$. Let $H$ be the orthogonal complement of $V$ with corresponding orthogonal projection $\text{pr}_H$ and define a second order operator $L$ on $M$ by

$$\begin{align*}
Lf &= \text{div} (\text{pr}_H \nabla f), \quad f \in C^\infty(M).
\end{align*}$$

If $H$ satisfies the bracket-generating condition, meaning that the sections of $H$ along with their iterated brackets span the entire tangent bundle, then $L$ is a hypoelliptic operator by Hörmander’s classical theorem [28]. The operator $L$ corresponds to the sub-Riemannian metric $g_H = g|_H$. Let us make the additional assumption that leaves of the foliation are totally geodesic submanifolds of $M$ and that the foliation is Riemannian. If only the first order brackets are needed to span the entire tangent bundle, it is known that any $\frac{1}{2}L$-diffusion $X_t$ has infinite lifetime given certain curvature bounds [24, Theorem 3.4]. Furthermore, if $H$ satisfies the Yang-Mills condition, then no assumption on the number of brackets needed to span the tangent bundle is necessary [11, Section 4], see Remark 3.15 for the definition of the Yang-Mills condition. Under the same restrictions, for any smooth function $f$ with bounded gradient, $t \mapsto \|\nabla P_t f\|_{L^\infty(g)}$ remains bounded on a finite interval.

We will show how to modify the argument in [11] to go beyond the requirement of the Yang-Mills condition and even beyond foliations. We will start with some preliminaries on sub-Riemannian manifolds and sub-Laplacians in Section 2. In Section 3.1 we will show that the existence of a Weitzenböck-type formula for a connection sub-Laplacian is always corresponds to adjoint of a connection compatible with a sub-Riemannian structure. Our results on infinite lifetime are presented in Section 3.3 based on a Feynman-Kac representation of $dP_t f$ using a particular adjoint of a compatible connection. Using recent results of [17], we also show that our curvature requirement in the case of totally geodesic foliations implies that the Brownian motion of the full Riemannian metric $g$ has infinite lifetime as well, see Section 3.7.

Our Feynman-Kac representation in Section 3.3 uses parallel transport with respect to a connection that does not preserve the horizontal bundle. We give an alternative stochastic representation if $dP_t f$ using parallel transport along a connection that preserves our sub-Riemannian structure in Section 4.1. This rewritten representation allows us to give an explicit pointwise bound for the horizontal gradient in Carnot groups. For a smooth function $f$ on $M$, the horizontal gradient $\nabla^H f$ is defined by the condition that $\alpha(\nabla^H f) = \sigma(L)(df, \alpha)$ for any $\alpha \in T^*M$. Carnot groups are the ‘flat model spaces’ in sub-Riemannian geometry in the sense that their role is similar to that of Euclidean spaces in Riemannian geometry. See Section 4.3 for the definition. It is known that there exists pointwise bounds for the horizontal gradient on Carnot groups. From [31], there exists constants $C_p$ such
that
\begin{equation}
|\nabla^H P_t f|_{g_H} \leq C_p \left( P_t|\nabla^H f|_{g_H}^p \right)^{1/p}, \quad p \in (1, \infty),
\end{equation}
holds pointwise for any \( t > 0 \). The constant \( C_p \) has to be strictly larger than 1, see [15]. We give explicit constants the gradient estimates on Carnot groups. This result improves on the constant found in [3] for the special case of the Heisenberg group. Also, for \( p > 2 \) we find a constant that does not depend on the heat kernel.

Appendix A deals with Feynman-Kac representations of semigroups whose generators are not necessarily self-adjoint, which is needed for the result in Section 3.3.

2. Sub-Riemannian manifolds and sub-Laplacians

2.1. Sub-Riemannian manifolds. We define a sub-Riemannian manifold as a triple \((M, H, g_H)\) where \( M \) is a connected manifold, \( H \subseteq TM \) is a subbundle of the tangent bundle and \( g_H \) is a metric tensor defined only on \( H \). Such a structure induces a map \( \sharp^H : T^*M \to H \subseteq TM \) by the formula
\begin{equation}
\alpha(v) = g_H(\sharp^H \alpha, v) = :\langle \sharp^H \alpha, v \rangle_{g_H} \quad \alpha \in T_x^*M, \; v \in H_x, \; x \in M.
\end{equation}
The kernel of this map is the subbundle \( \text{Ann}(H) \subseteq T^*M \) of covectors vanishing on \( H \). This map \( \sharp^H \) induces a cometric \( g_H^\sharp \) on \( T^*M \) by the formula
\begin{equation}
\langle \alpha, \beta \rangle_{g_H^\sharp} = \langle \sharp^H \alpha, \sharp^H \beta \rangle_{g_H},
\end{equation}
which is degenerate unless \( H = TM \). Conversely, a given cometric \( g_H^\sharp \) degenerating along a subbundle of \( T^*M \), we can define \( \sharp^H \alpha = g_H^\sharp(\alpha, \cdot) \) and use (2.2) to obtain \( g_H \).

Going forward, we will refer to \( g_H^\sharp \) and \((H, g_H)\) interchangeably as a sub-Riemannian structure on \( M \). We will call \( H \) the horizontal bundle. For the rest of the paper, \( n \) is the rank of \( H \) while \( n + \nu \) denotes the dimension of \( M \).

Let \( \mu \) be a chosen smooth volume density with corresponding divergence \( \text{div}_\mu \). Relative to \( \mu \), we can define a second order operator
\begin{equation}
\Delta_H f := \Delta_{g_H} f = \text{div}_\mu \nabla^H df.
\end{equation}
By means of definition (1.1), the symbol of \( \Delta_H \) satisfies \( \sigma(\Delta_H) = g_H^\sharp \). Locally the operator \( \Delta_H \) can be written as
\[ \Delta_H f = \sum_{i=1}^n A_i^2 f + A_0 f, \quad n = \text{rank} H, \]
where \( A_0, A_1, \ldots, A_n \) are vector fields taking values in \( H \) such that \( A_1, \ldots, A_n \) form a local orthonormal basis of \( H \).

The horizontal bundle \( H \) is called bracket-generating if the sections of \( H \) along with its iterated brackets span the entire tangent bundle. The horizontal bundle is said to have step \( k \) at \( x \) if \( k - 1 \) is the minimal order of iterated brackets needed to span \( T_x M \). From the local expression of \( \Delta_H \), it follows that \( H \) is bracket-generating if and only if \( \Delta_H \) satisfies the strong Hörmander condition [28]. We shall assume that this condition indeed holds, giving us that both \( \Delta_H \) and \( \frac{1}{2} \Delta_H - \partial_t \) are hypoelliptic and that
\begin{equation}
\delta_{g_H}(x, y) := \sup \{ |f(x) - f(y)| : f \in C_c^\infty(M), \; \sigma(\Delta_H)(df, df) \leq 1 \},
\end{equation}
is a well defined distance on \( M \). Here, and in the rest of the paper, \( C_c^\infty(M) \) denotes the smooth, compactly supported functions on \( M \). Alternatively, the distance \( \delta_{g_H}(x, y) \) can be realized as the infimum of the lengths of all absolutely continuous
curves tangent to $H$ and connecting $x$ and $y$. The bracket-generating condition ensures that such curves always exist between any pair of points. For more information on sub-Riemannian manifolds, we refer to [33].

In what follows, we will always assume that $H$ is bracket-generating, unless otherwise stated explicitly. We note that if $\Delta_H$ satisfies the strong Hörmander condition and if $d_{g_H}$ is a complete metric, then $\Delta_H|_{C_0^\infty(M)}$ is essentially self-adjoint by [38, Chapter 12].

For the remainder of the paper, we make the following notational conventions. If $p : E \to M$ is a vector bundle, we denote by $\Gamma(E)$ the space of smooth sections of $E$. If $E$ is equipped with a connection $\nabla$ or a (possibly degenerate) metric tensor $g$, we denote the induced connections on $E^\ast$, $\bigwedge^2 E$, etc. by the same symbol, while the induced metric tensors are denoted by $g^\ast$, $\wedge^2 g$, etc. For elements $e_1, e_2$, we write $g(e_1, e_2) = \langle e_1, e_2 \rangle$ and $|e_1| = \langle e_1, e_1 \rangle^{1/2}$ even in the cases when $g$ is only positive semi-definite. If $\mu$ is a chosen volume density on $M$ and $f$ is a function on $M$, we write $\|f\|_{L^p}$ for the corresponding $L^p$-norm with the volume density being implicit. If $Z \in \Gamma(E)$ then $\|Z\|_{L^p(g)} := \|Z\|_{L^p}$.

For $x \in M$, if $\alpha \in \text{End}_{T_x} M$ is an endomorphism, we will let $\alpha^T \in \text{End}_{T_x^\ast} M$ denote its transpose. If $g$ has a Riemannian metric, then $\alpha^* \in \text{End}_{T_x^\ast} M$ denotes its dual. In other words,

$$\langle \alpha^T v, w \rangle_g = \langle v, \alpha^* w \rangle_g, \quad (\alpha^T \alpha)(v) = \alpha(\alpha^* v), \quad \alpha \in T_x^\ast M, \quad v, w \in T_x M.$$ 

The same conventions apply for endomorphisms of $T^\ast M$. If $\alpha$ is a differential operator, then $\alpha^*$ is defined with respect to the $L^2$-inner product of $g$.

### 2.2. Taming metrics

Given a sub-Riemannian manifold $(M, H, g_H)$, a Riemannian metric $g$ on $M$ is said to tame $g_H$ if $g|H = g_H$. If $d_g$ is the corresponding Riemannian distance, then $d_g(x, y) \leq d_{g_H}(x, y)$ for any $x, y \in M$, since curves tangent to $H$ have equal length with respect to both metrics, while $d_g$ considers the infimum of the lengths over curves that are not tangent to $H$ as well. It follows that if $d_g$ is complete, then $d_{g_H}$ is a complete metric as well, as observed in [38, Theorem 7]. By [37, Theorem 2.4], if $g$ is a complete Riemannian metric taming $g_H$, then the sub-Laplacian $\Delta_g$ with respect to the volume density of $g$ and the Laplace-Beltrami operator $\Delta$ are both essentially self-adjoint on $C_0^\infty(M)$.

We then denote the corresponding orthogonal projection to $H$ by $\text{pr}_H$. Let $\theta : TM \to T^\ast M$ be the vector bundle isomorphism $v \mapsto \langle v, \cdot \rangle_{g_H}$ with inverse $\sharp$. The fact that $g$ tames $g_H$ is equivalent to the statement $g_H^\sharp = \text{pr}_H \sharp$. Let $V$ denote the orthogonal complement of $H$ with corresponding projection. The curvature $\mathcal{R}$ and the cocurvature $\mathcal{R}$ of $H$ with respect to the complement $V$ are defined as

$$\mathcal{R}(A, Z) = \text{pr}_V [\text{pr}_H A, \text{pr}_H Z], \quad \mathcal{R}(A, Z) = \text{pr}_H [\text{pr}_V A, \text{pr}_V Z],$$

for $A, Z \in \Gamma(TM)$. By definition, $\mathcal{R}$ and $\mathcal{R}$ are vector-valued two-forms, and $\mathcal{R}$ vanishes if and only if $V$ is integrable. The curvature and the cocurvature only depend on the direct sum $TM = H \oplus V$ and not the metrics $g_H$ or $g$.

### 2.3. Connections compatible with the metric

Let $\nabla$ be an affine connection on $TM$. We say that $\nabla$ is compatible with the sub-Riemannian structure $(H, g_H)$ or $g^\sharp_H$ if $\nabla g^\sharp_H = 0$. This condition is equivalent to requiring that $\nabla$ preserves the horizontal bundle $H$ under parallel transport and that $Z(A_1, A_2)_{g_H} = (\nabla_Z A_1, A_2)_{g_H} + (A_1, \nabla_Z A_2)_{g_H}$ for any $Z \in \Gamma(TM)$, $A_1, A_2 \in \Gamma(H)$. For any sub-Riemannian manifold $(M, H, g_H)$, the set of compatible connections is non-empty.
Let \( \tilde{g} \) be any Riemannian metric on \( M \) and define \( V \) as the orthogonal complement to \( H \). Let \( \text{pr}_H \) and \( \text{pr}_V \) be the corresponding orthonormal projections. Define

\[
g = \text{pr}_H g_H + \text{pr}_V \tilde{g} V.
\]

Then \( g \) is a metric taming \( g_H \). Let \( \nabla^g \) be the Levi-Civita connection of \( g \) and define finally

\[
\nabla^0 := \text{pr}_H \nabla^g \text{pr}_H + \text{pr}_V \nabla^g \text{pr}_V.
\]

The connection \( \nabla^0 \) will be compatible with \( g_H \) and also with \( g \).

2.4. Rough sub-Laplacians. In this section, we will introduce rough sub-Laplacians and compare them to the sub-Laplacian as defined in (2.3). Let \( g_H \in \Gamma(\text{Sym}^2 TM) \) be a sub-Riemannian structure on \( M \) with horizontal bundle \( H \). For any two-tensor \( \xi \in \Gamma(T^* M^\otimes 2) \) we write \( \text{tr}_H \xi(x, x) := \xi(g_H) \). We use this notation since for any \( x \in M \) and any orthonormal basis \( v_1, \ldots, v_n \) of \( H_x \)

\[
\text{tr}_H \xi(x)(x, x) = \sum_{i=1}^n \xi(x)(v_i, v_i).
\]

For any affine connection \( \nabla \) on \( TM \), define the Hessian \( \nabla^2 \) by

\[
\nabla^2_{A,B} = \nabla_A \nabla_B - \nabla_{\nabla_A B}.
\]

We define the rough sub-Laplacian \( L(\nabla) \) as \( L(\nabla) = \text{tr}_H \nabla^2_{\nabla_x x} \). Since \( \nabla \) induces a connection on all tensor bundles, \( L(\nabla) \) is defined as an operator on tensors in general. We have the following result.

**Lemma 2.1.** (a) Let \( \mu \) be a volume density on \( M \) with corresponding sub-Laplacian \( \Delta_H \). Assume that \( H \) is a proper subbundle in \( TM \). Then there exists some connection \( \nabla \) compatible with \( g_H \) and satisfying \( L(\nabla) f = \Delta_H f \).

(b) Let \( g \) be a Riemannian metric taming \( g_M \) and with volume form \( \mu \). Let \( \nabla \) be a connection compatible with both \( g_H \) and \( g \). Let \( T^\nabla \) be the torsion of \( \nabla \) and define the one-from \( \beta \) by

\[
\beta(v) = \text{tr} T^\nabla(v, \cdot).
\]

Then the dual of \( L = L(\nabla) \) on tensors is given by

\[
L^* = L - 2\nabla^* \nabla \beta - \text{div}_\mu \beta H^H = L + (\nabla^* \nabla \beta)^* - \nabla^* \beta H^H.
\]

In particular, \( L f = \Delta_H f + \langle \beta, df \rangle g^*_H \) for any \( f \in C^\infty(M) \).

**Proof.** (a) If \( H \) is properly contained in \( TM \), then there is some Riemannian metric \( g \) such that \( g|H = g_H \) and such that \( \mu \) is the volume form \( g \). Define \( \nabla^0 \) as in (2.6) and for any endomorphism valued one-form \( \kappa \in \Gamma(T^* M \otimes \text{End} T^* M) \), define a connection \( \nabla^\kappa = \nabla^0 + \kappa(v) \). The connection \( \nabla^\kappa \) is compatible with \( \nabla^0 \) if and only if

\[
\langle \kappa(v) \alpha, \alpha \rangle g_H = 0, \quad v \in TM, \alpha \in T^* M.
\]

Furthermore, \( L(\nabla^\kappa) = L(\nabla^0) f + (\text{tr}_H \kappa(x) \nabla_x) f \).

Define \( Z = \Delta_H - L(\nabla^0) \). We want to show that there is an endomorphism-valued one-form \( \kappa \) such that \( \text{tr}_H \kappa(x) \nabla_x = Z \) and such that (2.7) holds. By a partition of unity argument, it is sufficient to consider \( Z \) as defined on a small
enough neighborhood $U$ such that both $TM$ and $H$ are trivial. Let $\eta$ be any
one-form on $U$ such that

$$\langle \eta, \beta \rangle_{\tilde{g}_H} = 1, \quad \eta(Z) = 0.$$ 

Let $\zeta$ be a one-form such that $\tilde{g}_H \zeta = Z$. Define $\kappa$ by

$$\kappa(v)\alpha = \eta(v)(\alpha(Z)\eta - \alpha(\tilde{g}_H \eta)\zeta).$$

This one-form $\kappa$ has the desired properties.

(b) For any connection $\nabla$ preserving the Riemannian metric $g$, we have

$$\text{div}_\mu Z = \sum_{i=1}^n \langle \nabla_{A_i} Z, A_i \rangle_g + \sum_{s=1}^\nu \langle \nabla_{Z_s} Z, Z_s \rangle_g - \beta(Z),$$

with respect to local orthonormal bases $A_1, \ldots, A_n$ and $Z_1, \ldots, Z_\nu$ of respectively $H$ and $V$.

For any pair of vector fields $A$ and $B$ consider an operator $F(A \otimes B) = \flat A \otimes \nabla_B$ on tensors with dual

$$F(A \otimes B)^* = -t(\flat \nabla B)_A - t\nabla_{\flat B} A - t_A \nabla_B.$$

Extend $F$ to arbitrary sections of $TM^{\otimes 2}$ by $C^\infty(M)$-linearity. Consider the operator $F(\tilde{g}_H)$. Since $\nabla$ preserves $H$, its orthogonal complement $V$ and their metrics, around any point $x$ we can find local orthonormal bases $A_1, \ldots, A_n$ and $Z_1, \ldots, Z_\nu$ of respectively $H$ and $V$ that are parallel at any arbitrary point $x$. Hence, in any local orthonormal basis

$$F(\tilde{g}_H)^* = t_{4\mu \beta} - \sum_{i=1}^n t_{A_i} \nabla_{A_i},$$

and so

$$F(\tilde{g}_H)^* F(\tilde{g}_H) = -L + \nabla_{2\mu \beta} = -L^* + (\nabla_{4\mu \beta})^*.$$

**Remark 2.2.** As a result of the proof of Lemma 2.1, we actually know that all second order operators on the form $L(\nabla^0) + Z$ for some $Z \in \Gamma(H)$ is given as the rough sub-Laplacian of some connection compatible with the metric $g_H$.

3. **Adjoint connections and infinite lifetime**

3.1. **A Weitzenböck formula for sub-Laplacians.** In the case of Riemannian geometry $g_H = g$, one of the central identities involving the rough Laplacian of the Levi-Civita connection $L(\nabla^0)$ is the Weitzenböck formula $L(\nabla^0)df = \text{Ric}_g(\tilde{\partial}df, \cdot) + dL(\nabla^0)f = \text{Ric}_g(\tilde{\partial}df, \cdot) + d\Delta_g f$. A similar formula can be introduced in sub-Riemannian geometry, as was observed in [19] using the concept of adjoint connections. Adjoint connections was first considered in [14].

If $\nabla$ is a connection on $TM$ with torsion $T_{\nabla}$, then its adjoint $\hat{\nabla}$ is defined by

$$\hat{\nabla}_A B = \nabla_A B - T_{\nabla}(A, B).$$

for any $A, B \in \Gamma(TM)$. We remark that $-T_{\nabla}$ is the torsion of $\hat{\nabla}$, so $\nabla$ is the adjoint of $\hat{\nabla}$. 

Proposition 3.1 (Sub-Riemannian Weitzenböck formula). Let $L$ be any rough sub-Laplacian of an affine connection. Then there exists a vector bundle endomorphism $\mathcal{A} : T^*M \to T^*M$ such that for any $f \in C^\infty(M)$,
\begin{equation}
(L - \mathcal{A})df = dLf
\end{equation}
if and only if $L = L(\hat{\nabla})$ for some adjoint $\hat{\nabla}$ of a connection $\nabla$ that is compatible with $g^H$. In this case, $\mathcal{A} = \text{Ric}(\nabla)$, where
\begin{equation}
\text{Ric}(\nabla)(\alpha)(v) := \text{tr}_H R^\hat{\nabla}(x,v)\alpha(x).
\end{equation}

We note that bracket-generating assumption is not necessary for this result.

Remark 3.2. (i) Let $\nabla$ be a connection satisfying $\nabla g^H = 0$ and let $\hat{\nabla}$ be its adjoint. By [21, Proposition 2.1] any smooth curve $\gamma$ in $M$ is a normal sub-Riemannian geodesic if and only if there is a one-form $\lambda(t)$ along $\gamma(t)$ such that
$$\gamma^H \lambda(t) = \dot{\gamma}(t), \quad \text{and} \quad \hat{\nabla}_t \lambda(t) = 0.$$ See the reference for the definition of normal geodesic. In this sense, adjoints of compatible connections occur naturally in sub-Riemannian geometry.

(ii) A Weitzenböck formula in the sub-Riemannian case first appeared in [19, Chapter 2.4]. See also [18]. This formulation assumes that the connection $\nabla$ can be represented as a Le Jan-Watanabe connection. For definition and the proof of the fact that all connections on a vector bundle compatible with some metric there are of this type, see [19, Chapter 1]. We will do the proof of Proposition 3.1 without this assumption, in order to obtain an equivalence between existence of a Weitzenböck formula and being an adjoint of a compatible connection.

Before continuing with the proof, we will need the next lemma.

Lemma 3.3. Let $\nabla$ be an affine connection with adjoint $\hat{\nabla}$. Assume that $\nabla$ is compatible with $g^H$ and denote $L = L(\nabla)$, $\text{Ric} = \text{Ric}(\nabla)$ and $\hat{L} = L(\hat{\nabla})$. For any endomorphism-valued one-form $\kappa \in \Gamma(T^*M \otimes \text{End} T^*M)$ let $\nabla^\kappa$ be the connection
\begin{equation}
\nabla^\kappa_v := \nabla_v + \kappa(v), \quad v \in TM.
\end{equation}
(a) If the horizontal bundle $H$ is a proper subbundle of $TM$, but bracket-generating, then the connection $\nabla$ does not preserve $H$ under parallel transport.

(b) Define $L^\kappa = L(\nabla^\kappa)$. Then
$$L^\kappa f = Lf + Z^\kappa f \quad \text{and} \quad \hat{L} f = L f.$$ (c) The adjoint $\hat{\nabla}^\kappa$ of $\nabla^\kappa$ is given by $\hat{\nabla}_v^\kappa = \hat{\nabla}_v + \hat{\kappa}(v)$ where
$$\hat{\kappa}(v)\alpha(w) := (\kappa(w)\alpha)(v), \quad \text{for} \ v, w \in TM, \ \alpha \in T^*M.$$ In particular, if $\nabla^\kappa$ is compatible with $g^H$ then $\hat{\kappa}(\mathcal{A}^H)\alpha = 0$ for any $\alpha \in T^*M$.

Proof. (a) Let $A, B \in \Gamma(H)$ be any two vector fields such that $[A, B]$ is not contained in $H$. Observe that $\hat{\nabla}_A B = \nabla_B A + [A, B]$ then cannot be contained in $H$ either.
(b) This follows by direct computation: for any local orthonormal basis $A_1, \ldots, A_n$ of $H$, we have

$$L^\kappa = \sum_{i=1}^{n} (\nabla A_i + \kappa(A_i)) (\nabla A_i + \kappa(A_i))$$

$$- \sum_{i=1}^{n} \left( \nabla \nabla A_i, A_i - \kappa(A_i) \right)^\top A_i + \kappa(\nabla A_i, A_i - \kappa(A_i))^\top A_i \right)$$

$$= \sum_{i=1}^{n} \nabla A_i \nabla A_i + \sum_{i=1}^{n} \nabla A_i \kappa(A_i) + \sum_{i=1}^{n} \kappa(A_i) \nabla A_i + \sum_{i=1}^{n} \kappa(A_i) \kappa(A_i)$$

$$+ \nabla Z^\kappa + \kappa(Z^\kappa) - \sum_{i=1}^{n} \left( \nabla \nabla A_i, A_i + \kappa(\nabla A_i, A_i) \right)$$

$$= L + 2 \text{tr}_H \kappa(\nabla \nabla) = \text{tr}_H(\nabla \nabla) \kappa + \text{tr}_H \kappa(\nabla \nabla) + \nabla Z^\kappa + \kappa(Z^\kappa).$$

(c) Follows from the definition and (2.7) \hfill \square

**Proof of Proposition 3.1.** Notice that $\iota_A \nabla_B df = \iota_B \tilde{\nabla} A df$. Since $\nabla$ is compatible with $g_H$, for any $x \in M$ there is a local orthonormal basis $A_1, \ldots, A_n$ of $H$ such that $\nabla A_j(x) = 0$. Hence, for an arbitrary vector field $Z \in \Gamma(TM)$, with the terms below evaluated at $x \in M$ implicitly,

$$\iota_Z \delta L(\tilde{\nabla}) f = \iota_Z \delta L(\nabla) f = \sum_{i=1}^{n} \nabla A_i df(A_i) = \sum_{i=1}^{n} \nabla Z \nabla A_i df(A_i)$$

$$= \sum_{i=1}^{n} \iota_A \delta^\nabla (Z, A_i) df + \sum_{i=1}^{n} \nabla A_i \nabla Z df(A_i) + \nabla_{[Z,A_i]} df(A_i)$$

$$= - \text{Ric}(df)(Z) + \sum_{i=1}^{n} A_i \nabla Z df(A_i) - \nabla_{\nabla A_i} Z df(A_i)$$

$$= - \text{Ric}(df)(Z) + \sum_{i=1}^{n} A_i \tilde{\nabla} A_i df(Z) - \tilde{\nabla} A_i df(\tilde{\nabla} A_i Z)$$

$$= \iota_Z (\text{Ric}(df) + L(\tilde{\nabla}) df).$$

Since $x$ was arbitrary, it follows that $L(\tilde{\nabla})$ satisfies (3.1).

Conversely, suppose that $L = L(\nabla')$ is an arbitrary rough Laplacian of $\nabla'$. Let $\nabla$ be an arbitrary connection compatible with $g_H$ and define $\kappa$ such that $\nabla' = \nabla + \kappa$, where $\nabla$ is defined as in (3.3). Introduce vector field $Z = \text{tr}_H \kappa(\nabla')$ and first order operator $D = \text{tr}_H \kappa(\nabla')$. Using item (b) of Lemma 3.3, modulo zero order operators applied to $df$, $Ldf = dLdf$ equals $-dZf + \nabla Z df + 2D df$. Furthermore, $-dZf + \nabla Z df = (\nabla Z - \mathcal{L} Z) df$ and $(\nabla Z - \mathcal{L} Z)$ is a zero order operator. Hence, it follows that (3.1) holds if and only if $D df = \mathcal{C} df$ for some zero order operator $\mathcal{C}$ and any $f \in C^\infty(M)$.

Let $A_1, \ldots, A_n$ be a local orthonormal basis of $H$ and complete this basis to a full basis of $TM$ with vector fields $Z_1, \ldots, Z_\nu$. Let $A_1^*, \ldots, A_n^*, Z_1^*, \ldots, Z_\nu^*$ be the corresponding coframe. Observe that $Z_1^*, \ldots, Z_\nu^*$ is a basis for $\text{Ann}(H)$. For any
Let $B \in \Gamma(TM)$ and $f \in C^\infty(M)$,

$$(Ddf)(B) = \sum_{i,k=1}^n (\hat{\kappa}(A_i)A_k^*(B)) \hat{\nabla}_A df(A_k) + \sum_{i=1}^n \sum_{s=1}^n (\hat{\kappa}(A_i)Z_s^*(B)) \hat{\nabla}_A df(Z_s).$$

In order for this to correspond to a zero order operator, we must have $\hat{\kappa}(A_i)Z_s^* = 0$ and $\hat{\kappa}(A_i)(A^*_s) = -\hat{\kappa}(A_k)(A^*_l)$ which is equivalent to $\hat{\kappa}(f^H A) = 0$ for any $A \in T^*M$. Hence, $\hat{\nabla}_A$ is the adjoint of a connection compatible with $g_H^*$. \hfill $\Box$

3.2. Connections with skew-symmetric torsion. For the sub-Riemannian manifold $(M, H, g_H)$ with $H$ strictly contained in $TM$, there exists no torsion-free connection which is compatible with the metric. Indeed, if $\nabla$ is a connection preserving $H$, then the equality $\nabla_A B = \nabla_B A = [A, B]$ would imply that $H$ could be bracket-generating only if $H = TM$. For this reason, it has been difficult to find a direct analogue of the Levi-Civita connection in sub-Riemannian geometry.

For a Riemannian metric $g$, the only connections with the same geodesics as the Levi-Civita connection, are the compatible connections with skew-symmetric torsion. These connections $\nabla$ compatible with $g$ such that

$$\zeta(v_1, v_2, v_3) := -(T^\nabla(v_1, v_2), v_3)_g, \quad v_1, v_2, v_3 \in TM,$$

is a well defined three-form. The connection $\nabla$ is then given by formula $\nabla_A B = \nabla^g_A B - \frac{1}{2}\mathfrak{H}_{A,B} \zeta$. Equivalently, the connection $\nabla$ is compatible with $g$ and of skew-symmetric torsion if and only if we have both $\nabla g = 0$ and $\nabla \zeta = 0$. By Lemma 3.3 (a) we cannot have both $\nabla$ and $\nabla$ being compatible with $g_H^*$ in the proper sub-Riemannian case. In some cases, however, we have the following generalization.

Let $(M, H, g_H)$ be a sub-Riemannian manifold with taming Riemannian metric $g$ and $V = H^\perp$. Let $\mathcal{L}_A$ denote the Lie derivative with respect to the vector field $A$. Introduce a vector-valued symmetric bilinear tensor $H$ by the formula

$$\langle H(A, A), Z \rangle_g = -\frac{1}{2}\langle \mathcal{L}_{pr_V} z g \rangle(pr_H A, pr_H A) - \frac{1}{2}\langle \mathcal{L}_{pr_H} z g \rangle(pr_V A, pr_V A)$$

for any $A, Z \in \Gamma(TM)$. Observe that $H = 0$ is equivalent to the assumption

$$\langle \mathcal{L}_A g \rangle(Z, Z) = 0, \quad \langle \mathcal{L}_Z g \rangle(A, A) = 0,$$

for any $A \in \Gamma(H)$ and $Z \in \Gamma(V)$.

**Proposition 3.4.** Let $\nabla$ be a connection compatible with $g_H^*$ and with adjoint $\hat{\nabla}$. Assume that there exists a Riemannian metric $g$ taming $g_H$ such that $\nabla g = 0$. Then $H = 0$. Furthermore, if $\Delta_H$ is defined relative to the volume density of $g$, then

$$\left(L(\hat{\nabla}) - \text{Ric}(\nabla)\right)df = dL(\hat{\nabla})f = dL(\nabla)f = d\Delta_H f, \quad f \in C^\infty(M).$$

Conversely, suppose that $g$ is a Riemannian metric taming $g_H$ and satisfying $H = 0$. Define $\mathcal{R}$ and $\hat{\mathcal{R}}$ as in (2.5) and introduce a three-form $\zeta$ by

$$\zeta(v_1, v_2, v_3) = \circ \langle \mathcal{R}(v_1, v_2), v_3 \rangle_g + \circ \langle \hat{\mathcal{R}}(v_1, v_2), v_3 \rangle_g,$$

with $\circ$ denoting the cyclic sum. Then the connection

$$\nabla_A B = \nabla^g_A B - \frac{1}{2}\mathfrak{H}_{A,B} \zeta$$
is a connection compatible with $g_H^*$ and both it and its adjoint $\hat{\nabla}_A B = \nabla_A^g B + \frac{1}{2} \hat{\nabla}_A \zeta$ is compatible with $\nabla g = 0$.

Furthermore, among all such possible choices of connections, $\nabla$ gives the maximal value with regard to the lower bound of $\alpha \mapsto \langle \text{Ric}(\nabla) \alpha, \alpha \rangle_{g_H^*}$.

**Remark 3.5.**

(i) **Analogy to the Levi-Civita connection:** Applying Proposition 3.4 to the case when $g_H = g$ is a Riemannian metric, the Levi-Civita connection can be described as the connection such that both $\nabla$ and $\hat{\nabla}$ are compatible with $g$ and that also maximizes the lower bound $\alpha \mapsto \langle \text{Ric}(\nabla) \alpha, \alpha \rangle_{g^*}$, which was observed in [19, Corollary C.7]. In this sense, the connection in (3.7) is analogous to the Levi-Civita connection.

(ii) **Existence and uniqueness for a Riemannian metric $g$ taming $g_H$ and satisfying (3.5):** Every such Riemannian metric $g$ is uniquely determined by the orthogonal complement $V$ of $H$ and its value at one point [23, Remark 3.10]. Conversely, suppose that $(M, H, g_H)$ is a sub-Riemannian manifold and let $V$ be a subbundle such that $TM = H \oplus V$. Then one can use horizontal holonomy to determine if there exists a Riemannian metric $g$ taming $g_H$, satisfying (3.5) and making $H$ and $V$ orthogonal. See [13] for more details and examples where no such metric can be found. Two Riemannian metrics $g_1$ and $g_2$ may tame $g_H$, satisfy (3.5) and have the same volume density, but their orthogonal complements of $H$ may be different, see [23, Example 4.6] and [13, Example 4.2].

(iii) **Geometric interpretation of (3.5):** From [21], the condition (3.5) holds if and only if the Riemannian and the sub-Riemannian geodesic flow commute. See also Section 3.7 for more relations to geometry and explanation of the notation $\Pi$ for the tensor in (3.4).

(iv) If we define $\nabla$ as in (3.7) and assume $\mathcal{R} = 0$, then its adjoint $\hat{\nabla}$ equals the connection $\nabla^\varepsilon$ in [6] with $\varepsilon = \frac{1}{2}$.

**Proof.** Let $\nabla^g$ be the Levi-Civita connection of $g$. Define the connection $\nabla^0$ as in (2.6) which is compatible with both $g_H^*$ and the Riemannian metric $g$. Let $B$ be the torsion of $\nabla^0$. Define $\mathcal{R}$ and $\mathcal{R}$ as in (2.5). Write $T_Z$ for the vector valued form $T_Z(A) = T(Z, A)$ and use similar notation for $\mathcal{R}$, $\mathcal{R}$ and $\Pi$. By the definition of the Levi-Civita connection, we have

$$T_Z = -\mathcal{R}_Z + \frac{1}{2} \mathcal{R}_Z^* - \hat{\mathcal{R}}_Z + \frac{1}{2} \hat{\mathcal{R}}_Z^* + \Pi^*_Z - \Pi^*_Z - \frac{1}{2} \Pi^*_Z Z - \frac{1}{2} \hat{\Pi}^*_Z Z,$$

with dual

$$T^*_Z = -\mathcal{R}_Z^* + \frac{1}{2} \mathcal{R}_Z^* - \hat{\mathcal{R}}_Z + \frac{1}{2} \hat{\mathcal{R}}_Z^* + \Pi^*_Z - \Pi^*_Z + \frac{1}{2} \Pi^*_Z Z + \frac{1}{2} \hat{\Pi}^*_Z Z,$$

Hence, if we introduce $T^*_Z := \frac{1}{2}(T_Z + T^*_Z)$ then

$$2T^*_Z = -\frac{1}{2}(\mathcal{R}_Z + \mathcal{R}_Z^*) - \frac{1}{2}(\hat{\mathcal{R}}_Z + \hat{\mathcal{R}}_Z^*) + (\Pi^*_Z + \Pi^*_Z) - 2 \Pi^*_Z Z.$$

Let $\nabla'$ be a connection compatible with $g_H$. Define an End $T^*M$-valued one-from $\kappa$ such that $\nabla'_v = \nabla'^0_v + \kappa(v)$, and let $\nabla'_v = \nabla'^0_v + \hat{\kappa}(v)$ be its adjoint. Define

$$\hat{\kappa}^*(Z) = \frac{1}{2} (\hat{\kappa}(Z) + \hat{\kappa}(Z)^*), \quad \hat{\kappa}^0(Z) = \frac{1}{2} (\hat{\kappa}(Z) - \hat{\kappa}(Z)^*).$$
In order for the adjoint to be compatible with $g$, we must have

$$(\nabla^g_Z g)(A, A) = 2\langle (T_Z + \kappa(Z)^g)A, A \rangle_g = 0,$$

giving us the requirement $\kappa^*(Z)^g = -T_Z^g$. However, since $\nabla^g$ is compatible with $g_H$, we also have $\kappa(z^g H) = 0$ by Lemma 3.3. The latter condition is equivalent to $\kappa(A)^g(A + B) = 0$ for any $A \in \Gamma(H)$ and $B \in \Gamma(V)$. This means that

$$0 = \langle \kappa(A)^g(A + B), A + B \rangle_g = \langle \kappa^*(Z)^g(A + B), A + B \rangle_g$$

$$= -\langle T_A^H(A + B), A + B \rangle_g = -\langle H(A, A), B \rangle_g + \langle A, H(B, B) \rangle_g.$$

This holds for any $A \in \Gamma(H)$ and $B \in \Gamma(V)$ if and only if $H = 0$. It follows that $4\kappa^*(Z)^g = R_Z + R_Z^* + R_Z^* Z$.

For the anti-symmetric part,

$$0 = -4\kappa(A)^T(A + B) = 4\kappa^*(A)^T(A + B) - 4\kappa^*(A)^T(A + B)$$

$$= 4\kappa^*(A)^T(A + B) - R_A^g B$$

for any $A \in \Gamma(H), B \in \Gamma(V)$. This relation and anti-symmetry gives us

$$\kappa^*(Z)^T(A + B) = \kappa^*(pr_V Z)(A + B) - 1/4\langle R_Z - R_Z^* \rangle(A + B) + t_{Z, A} \beta,$$

where $\beta$ is a three-form vanishing on $V$.

In conclusion, for any $Z_1, Z_2 \in \Gamma(TM)$,

$$\nabla^g_{Z_1} Z_2 = \nabla^g_{Z_1} Z_2 - \kappa(Z_2)^T(Z_1)$$

$$= \nabla^g_{Z_1} Z_2 - 1/4\langle 2 R^*_{Z_1} Z_2^* + R_{Z_1} Z_2^* + R_{Z_2} Z_1^* \rangle Z_1 + \kappa^*(pr_V Z_2)(Z_1) + t_{Z_1, Z_2} \beta.$$

Furthermore, since

$$\nabla^0_Z = \nabla^g_Z + 1/2 T_Z - 1/2 T^*_Z - 1/2 T^* Z$$

$$= \nabla^g_Z + 1/2 \left( -R_Z + 1/2 R^* Z - R_Z^* - 1/2 R^* Z - 1/2 R^* Z \right)$$

$$- 1/2 \left( -R^*_Z + 1/2 R^*_Z - R^*_Z + 1/2 R^*_Z + 1/2 R^*_Z + 1/2 R^*_Z \right)$$

$$= \nabla^g_Z + 1/2 \left( -R^*_Z + R^*_Z - R^*_Z + R^*_Z + R^*_Z + R^*_Z \right),$$

we get

$$\nabla^g_Z = \nabla^g_Z + 1/2 \left( -R_Z + R_Z^* - R_Z^* + R^*_Z + R^*_Z \right) Z_2 + \lambda(Z_2) Z_1 + t_{Z_1, Z_2} \beta$$

where $\lambda(Z) = 1/4\langle R^*_Z \rangle Z_1 - \kappa^*(pr_V Z) A$.

In conclusion, if $\nabla'$ and $\nabla''$ are compatible with $g^H_4$ and $g$ respectively, and $\nabla$ is defined as in (3.7), then $H = 0$ and

$$(3.8) \quad \nabla'_{Z_1} Z_2 = \nabla'^{\lambda \beta}_{Z_1} Z_2 := \nabla_{Z_1} Z_2 + \lambda(Z_2) Z_1 + t_{Z_1, Z_2} \beta,$$

for some three-form $\beta$ vanishing on $V$ and some $\text{End}TM$-valued one-form $\lambda$ vanishing on $H$ and satisfying $\lambda(v)^* = -\lambda(v), v \in TM$. It is simple to verify that $\text{tr} T^{\nabla' \lambda}(v, \cdot) = 0$ for any $v \in H$, and hence $L(\nabla') f = L(\nabla') f = \Delta_H f$ by Lemma 2.1.
All that remains to be proven is that
\[ \langle \alpha, \operatorname{Ric}(\nabla^{\lambda, \beta}) \alpha \rangle_{g_H^*} \leq \langle \alpha, \operatorname{Ric}(\nabla) \alpha \rangle_{g_H^*}. \]
If \( \nabla^\beta = \nabla^{0, \beta} \) then \( \tilde{L}^\beta := L(\tilde{\nabla}^\beta) = L(\tilde{\nabla}^{\lambda, \beta}) \) since \( \lambda \) vanishes on \( H \). If we define \( \tilde{L} = L(\tilde{\nabla}) \), then for any smooth function \( f \) and local orthonormal basis \( A_1, \ldots, A_n \) of \( H \),
\[
\tilde{L}^\beta df(Z) = \tilde{L} df(Z) + 2 \sum_{i=1}^n \hat{\nabla}_{A_i} df(\sharp_{A_i} \wedge Z^\beta)
\]
\[
\quad + \sum_{i=1}^n df(\sharp_{A_i} \wedge Z(\hat{\nabla}_{A_i} \beta)) + \sum_{i=1}^n df(\sharp_{A_i} \wedge \sharp_{A_i} \wedge Z^\beta)
\]
\[
= \tilde{L} df(Z) + \sum_{i=1}^n df(\tilde{\nabla}(A_i, \sharp_{A_i} \wedge Z^\beta)) + \sum_{i=1}^n (\hat{\nabla}_{A_i} \beta)(df, A_i, Z) - 2\langle \epsilon_{df} \beta, \epsilon_{Z^\beta} \rangle_{g_H^*}
\]
\[
= \tilde{L} df(Z) + 2\langle \operatorname{Ric}(\beta), \epsilon_{Z^\beta} \rangle_{g_H^*} - \text{tr}_H(\hat{\nabla} \times \beta)(\times, \sharp df, Z) - 2\langle \epsilon_{df} \beta, \epsilon_{Z^\beta} \rangle_{g_H^*}.
\]
We use that
\[
\langle \tilde{L}^\beta - \tilde{L} df, \alpha \rangle_g = \langle (\operatorname{Ric}(\nabla^\beta) - \operatorname{Ric}(\nabla)) df, \alpha \rangle_g = \langle (\operatorname{Ric}(\nabla^{\lambda, \beta}) - \operatorname{Ric}(\nabla)) df, \alpha \rangle_g.
\]
As a consequence, for any \( \alpha \in T^* M \),
\[
\langle \alpha, \operatorname{Ric}(\nabla^{\lambda, \beta}) \alpha \rangle_{g^*} = \langle \alpha, \operatorname{Ric}(\nabla) \alpha \rangle_{g^*} + 2\langle \epsilon_{df} \beta, \epsilon_{Z^\beta} \rangle_{g_H^*} - 2\langle \epsilon_{df} \beta, \epsilon_{Z^\beta} \rangle_{g_H^*}.
\]
Denoting \( \alpha_H = \operatorname{pr}_H^* \alpha \), we get
\[
\langle \alpha, \operatorname{Ric}(\nabla^{\lambda, \beta}) \alpha \rangle_{g^*} = \langle \alpha_H, \operatorname{Ric}(\nabla) \alpha_H \rangle_{g^*} - 2\langle \epsilon_{df} \beta, \epsilon_{Z^\beta} \rangle_{g_H^*}.
\]
The result follows. \( \square \)

3.3. Infinite lifetime of the sub-Riemannian Laplacian. Assume now that the taming \( g \) is a complete Riemannian metric. Then both the sub-Laplacian \( \Delta_H \) of \( \mu = \mu_g \) and the Laplacian \( \Delta_g \) are essentially self-adjoint on compactly supported functions. We denote their unique self-adjoint extension by the same symbol.

Let \( \nabla \) be a connection compatible with \( g_H^* \) and let \( X_t(\cdot) \) be the stochastic flow of \( \frac{1}{2}L(\nabla) \) with explosion time \( \tau(\cdot) \). For any \( x \in M \), let \( \langle \cdot, \cdot \rangle = \langle \cdot, \cdot \rangle_{g_H(x)} \) be parallel transport along \( X_t(x) \) with respect to \( \nabla \). Using arguments similar to [23, Section 2.5], we know that the anti-development \( W_t(x) \) at \( x \) determined by
\[
dW_t(x) = dX_t(x) \quad \text{and} \quad W_t(0) = 0 \in T_x M,
\]
is a Brownian motion in the inner product space \((H_x, \langle \cdot, \cdot \rangle_{g_H(x)})\) with lifetime \( \tau(x) \). Consider the semigroup \( P_t \) on bounded Borel measurable functions corresponding to \( X_t(\cdot) \)
\[
P_t f(x) = \mathbb{E}[1_{t<\tau(x)} f(X_t(x))].
\]
We want to make statements regarding the explosion time \( \tau(\cdot) \) using connections that are compatible with \( g_H^* \). Let \( C_0^\infty(M) \) denote the space of smooth bounded functions. For vector bundle endomorphism \( \mathcal{A} \) of \( T^* M \) write \( \mathcal{A} |_{X_t(\cdot)}(x) = \langle \cdot, \cdot \rangle_t^{-1} \mathcal{A}(X_t(x)) \rangle_t \) and let \( \mathcal{A} \) denote the parallel transport along \( X_t \) with respect to \( \nabla \).

We make the following two assumptions
\begin{enumerate}[(A)]
\item If \( H \) is defined as in (3.4), then \( H = 0 \).
\end{enumerate}
(B) Consider the two-form $C \in \Gamma(\Lambda^2 T^*M)$ defined by
\begin{equation}
C(v, w) = \text{tr} R(v, R(w, \cdot)) - \text{tr} R(w, R(v, \cdot)), \quad v, w \in TM.
\end{equation}

Suppose that $\delta C = 0$ where $\delta$ is the codifferential with respect to $g$.

(C) Let $\nabla$ be defined as in (3.7). Assume that there exists a constant $K \geq 0$ such that for $\text{Ric} = \text{Ric}(\nabla)$,
\[ \langle \text{Ric} \alpha, \alpha \rangle_{g^*} \geq -K |\alpha|^2_{g^*}. \]

**Theorem 3.6.** Assume that (A), (B) and (C) hold. Then we have the following results.

(a) $\Delta_H$ and $\Delta_H$ spectrally commute.

(b) $\tau(x) = \infty$ a.s. for any $x \in M$.

(c) Define $\mathring{Q}_t = \mathring{Q}_t(x) \in \text{End} T_x^*M$ as solution to the ordinary differential equation
\[ \frac{d}{dt} \mathring{Q}_t = -\frac{1}{2} \mathring{Q}_t \text{Ric}_{\mathring{Q}_t}, \quad \mathring{Q}_0 = \text{id}. \]

Then, for any $f \in C^\infty_b(M)$ with $\| df \|_{L^\infty(g^*)} < \infty$, we have
\[ dP_t f(x) = \mathbb{E}[\mathring{Q}_t/\mathring{Q}_t^{-1} df(X_t(x))] \]
and
\[ \| dP_t f \|_{L^\infty(g^*)} \leq e^{Kt} \| df \|_{L^\infty(g^*)}. \]

In particular,
\[ \sup_{t \in [0, t_1]} \| dP_t f \|_{L^\infty(g^*)} \leq e^{Kt} \| df \|_{L^\infty(g^*)} < \infty \]
whenever $\| df \|_{L^\infty(g^*)} < \infty$.

Remark that since $\nabla$ preserves $H$ under parallel transport, and hence also $\text{Ann}(H)$, we have $\text{Ric} \alpha = 0$ for any $\alpha \in \text{Ann}(H)$. For this reason it is not possible to have a positive lower bound of $\langle \text{Ric} \alpha, \alpha \rangle_{g^*}$ unless $H = TM$. The results of Theorem 3.6 appear as necessary conditions for the $\Gamma_2$-calculus on sub-Riemannian manifolds, see e.g. [10, 11, 24]. We will use the remainder of this section to prove this statement.

### 3.4. Anti-symmetric part of Ricci curvature

Let $\zeta$ and $\nabla$ be as in (3.6) and (3.7). The operator $\text{Ric}(\nabla)$ is not in general symmetric. We consider the anti-symmetric part. Define $\text{Ric}^a = \text{Ric}(\nabla)$ and
\begin{equation}
\text{Ric}^a = \frac{1}{2} (\text{Ric} + \text{Ric}^*), \quad \text{Ric}^a = \frac{1}{2} (\text{Ric} - \text{Ric}^*).
\end{equation}

**Lemma 3.7.** For any $\alpha, \beta \in T^*M$,
\[ 2 \langle \text{Ric}^a \alpha, \beta \rangle_{g^*} = \text{tr}_H (\nabla \times \zeta)(\times, \omega, \beta). \]

In particular,
\[ \langle \beta, \text{Ric}^a \alpha \rangle_{g^*} = \langle \text{pr} \zeta \beta, \text{Ric}^a \alpha \rangle_{g^*} - \langle \beta, \text{Ric}^a \text{pr} \zeta \alpha \rangle_{g^*}, \]
so if $\text{Ric}^a$ has a lower bound then $\text{Ric}^a$ is a bounded operator. Furthermore, if we define $C$ by (3.9), then whenever the $L^2$ inner product is finite
\[ \langle \text{Ric}^a df, d\phi \rangle_{L^2(g^*)} = \langle C, df \wedge d\phi \rangle_{L^2(g^*)} \quad \text{for any } f, \phi \in C^\infty(M). \]
The first part of this result is also found in [19, Proposition C.6]. The condition \( \text{Ric} = 0 \) is called the Yang-Mills condition when \( \mathcal{R} = 0 \). For more details, see Remark 3.15.

**Proof of Lemma 3.7.** Write \( \odot \) for the cyclic sum. By the first Bianchi identity

\[
2\langle \text{Ric}^\alpha, \alpha, \beta \rangle_g = \sum_{i=1}^n \langle A_i, R^\nabla(A_i, \sharp \beta) \sharp \alpha \rangle_g - \sum_{i=1}^n \langle A_i, \odot (\nabla A_i, T) (\sharp \alpha, \sharp \beta) + \odot T(T(A_i, \sharp \alpha), \sharp \beta) \rangle_g
\]

\[
= - \sum_{i=1}^n \langle A_i, \odot R^\nabla(A_i, \sharp \alpha) \sharp \beta \rangle_g - \sum_{i=1}^n \langle A_i, \odot (\nabla A_i, T) (\sharp \alpha, \sharp \beta) + \odot T(T(A_i, \sharp \alpha), \sharp \beta) \rangle_g
\]

\[
= \sum_{i=1}^n (\nabla_{A_i} \zeta)(A_i, \sharp \alpha, \sharp \beta) - \sum_{i=1}^n \langle T(A_i, \sharp \alpha), T(\sharp \beta, A_i) \rangle_g - \sum_{i=1}^n \langle T(\sharp \beta, A_i), T(\sharp \alpha, A_i) \rangle_g
\]

\[
= \text{tr}_{\mathcal{H}}(\nabla_x \zeta)(\times, \sharp \alpha, \sharp \beta).
\]

Write \( \zeta = \zeta_H + \zeta_V \), where \( \zeta_H(v_1, v_2, v_3) = \odot \langle v_1, \mathcal{R}(v_2, v_3) \rangle \) and \( \zeta_V(v_1, v_2, v_3) = \odot \langle v_1, \mathcal{R}(v_2, v_3) \rangle \). Since for \( \alpha, \beta \in \text{Ann}(H) \)

\[
2\langle \text{Ric}^\alpha, \alpha, \beta \rangle_g = 0 = \text{tr}_{\mathcal{H}}(\nabla_x \zeta)(\times, \sharp \alpha, \sharp \beta) = \text{tr}_{\mathcal{H}}(\nabla_x \zeta_V)(\times, \sharp \alpha, \sharp \beta),
\]

we can write \( \langle \text{Ric}_3, \alpha, \beta \rangle = \text{tr}_{\mathcal{H}}(\nabla_x \zeta)(\times, \sharp \alpha, \sharp \beta) \). Observe also that by reversing the place of \( V \) and \( H \) and writing \( \mathcal{R}_V = \mathcal{R}_V \), we have also \( \text{tr}_{\mathcal{H}}(\nabla_x \zeta)(\times, \sharp \alpha, \sharp \beta) = 0 \).

Continuing, if \( A_1, \ldots, A_n \) and \( Z_1, \ldots, Z_n \) are local orthonormal bases of \( H \) and \( V \), respectively, observe that since \( \nabla \) preserves the metric \( g \), for any one-from \( \eta \), we have

\[
d\eta = \sum_{i=1}^n \iota_{A_i} \nabla_{A_i} \eta + \sum_{i=1}^n \iota_{Z_i} \nabla_{Z_i} \eta + \iota_T \eta,
\]

where \( \iota_T \eta = \eta(T(\cdot, \cdot)) \). The formula above becomes valid for arbitrary forms \( \eta \) if we extend \( \iota_T \) by rule \( \iota_T(\alpha \wedge \beta) = (\iota_T \alpha) \wedge \beta + (-1)^k \alpha \wedge (\iota_T \beta) \) for any \( k \)-form \( \alpha \) and form \( \beta \). Observe that for any \( v \in TM \), \( \text{tr} T(v, \cdot) = 0 \). Using similar arguments to the proof of Lemma 2.1 (b), we obtain a local formula for the codifferential

\[
\delta \eta = - \sum_{i=1}^n \iota_{A_i} \nabla_{A_i} \eta - \sum_{i=1}^n \iota_{Z_i} \nabla_{Z_i} \eta + \iota_T \eta.
\]

This means that

\[
\text{tr}_{\mathcal{H}}(\nabla_x \zeta_H)(\times, \sharp \alpha, \sharp \beta) = (\iota_T \zeta_H)(\sharp \alpha, \sharp \beta) - (\delta \zeta_H)(\sharp \alpha, \sharp \beta)
\]

\[
= \langle C - \delta \zeta_H, \alpha \wedge \beta \rangle_g,
\]

Inserting \( \alpha \wedge \beta = df \wedge d\phi = d(f \phi) \) and integrating over the manifold, we have the result. \( \square \)

### 3.5. Commutation relations with between the Laplacian and the sub-Laplacian.

Let \((M, g_H)\) be a sub-Riemannian manifold and let \( g \) be a taming Riemannian metric with \( \mathcal{H} = 0 \). Define \( \Delta_g \) as the Laplacian of \( g \) and let \( \Delta_H \) be defined relative to the volume form of \( g \).

**Proposition 3.8.** Define \( C \) as in (3.9).

(a) We have \( \Delta_g \Delta_H f = \Delta_H \Delta_g f \), for all \( f \in C^\infty(M) \) if and only if \( \delta C = 0 \).

(b) Assume \( \delta C = 0 \) and that \( \text{Ric}(\nabla) \) is bounded from below by a constant \(-K\).

Then \( \Delta_g \) and \( \Delta_H \) spectrally commute.
Before stating the proof, we will need the following lemmas.

**Lemma 3.9** ([30, Proposition], [10, Proposition 4.1]). Let $\mathcal{A}$ be equal to the Laplacian $\Delta_g$ or sub-Laplacian $\Delta_H$ defined relative to a complete Riemannian or sub-Riemannian metric, respectively. Let $M \times [0, \infty)$, $(x, t) \mapsto u_t(x)$ be a function in $L^2$ of the solving the heat equation

$$(\partial_t - \mathcal{A})u_t = 0, \quad u_0 = f,$$

for an $L^2$-function $f$. Then $u_t(x)$ is the unique solution to this equation in $L^2$.

**Lemma 3.10.** Let $(M, H, g_H)$ be a sub-Riemannian manifold and define $\Delta_H$ as the sub-Laplacian with respect to a volume form $\mu$. Let $g$ be a taming metric of $g_H$ with volume form $\mu$. Assume that $\nabla$ and its adjoint $\nabla^*$ are compatible with $g^*_H$ and $g$, respectively. If $\hat{L} = L(\nabla)$, then with respect to $g$, $\hat{L}^* = \hat{L} = - (\nabla^*_p r) \nabla^*_p r$. In particular, $\hat{L}f = \Delta_H f$ for any $f \in C^\infty(M)$.

**Proof.** Define $\hat{F}(A \otimes B) = bA \otimes \nabla B$ and extend it by linearity to all sections of $TM^\otimes 2$. Again we know that for any point $x$, there exists a basis $A_1, \ldots, A_n$ such that $\nabla A_i(x) = 0$. This means that $\nabla_x A_i(x) = T^\nabla(A_i, Z)(x)$ for the same basis, and hence locally

$$\hat{F}(g^*_H)^* \hat{F}(g^*_H) = - \hat{L}$$

However, $\nabla$ is the adjoint of a connection compatible with $g^*_H$ we have $\hat{\beta} = 0$ since $\nabla$ has to be on the form (3.8). Hence $\hat{F}(g^*_H)^* \hat{F}(g^*_H) = - \hat{L}$ and the result follows. \hfill $\square$

**Proof of the Proposition 3.8.**

(a) It is sufficient to prove the statement for compactly supported functions. Note that for $f, \phi \in C^\infty_c(M)$, $(\Delta_H \Delta_g f, \phi)_{L^2} = (f, \Delta_g \Delta_H \phi)_{L^2}$. Hence, we need to show that $\Delta_g \Delta_H$ is its own dual on compact supported forms.

Let $\nabla$ be as in (3.7) with adjoint $\nabla^*$. Define $\hat{L} = L(\nabla), \hat{L} = L(\nabla^*), \text{Ric} = \text{Ric}(\nabla)$ and introduce $\text{Ric}^a = \frac{1}{2} (\text{Ric} - \text{Ric}^*)$. By Lemma 3.10 we have $\hat{L}^* = \hat{L}$. In addition,

$$(\Delta_g \Delta_H f, \phi)_{L^2(\nabla^*)} = - \langle df, df \rangle_{L^2(\nabla^*)} = - \langle (\hat{L} - \text{Ric}) df, df \rangle_{L^2(\nabla^*)} = - \langle df, (\hat{L} - \text{Ric}) df \rangle_{L^2(\nabla^*)} + 2 \langle \text{Ric}^a df, df \rangle_{L^2(\nabla^*)}$$

Furthermore, $2 \langle \text{Ric}^a df, df \rangle_{L^2} = \langle \text{C}, df \wedge df \rangle_{L^2} = \langle \delta \text{C}, f df \rangle_{L^2}$. Since all one-forms can be written as sums of one-forms of the type $f df$, it follows that $(\Delta_g \Delta_H)^* f = \Delta_g \Delta_H f$ for $f \in C^\infty_c(M)$ if and only if $\delta \text{C} = 0$.

(b) Write $\Delta_g = \Delta_H + \Delta_V$ and $df = dh f + dV f$, with $dh f = \text{pr}_H df$ and $dV f = \text{pr}_V df$. Then $\langle \Delta_H f, \phi \rangle_{L^2(\nabla^*)} = - \langle df, dh \phi \rangle$ and similarly for $\Delta_V$.

Observe that for any compactly supported $f$,

$$\|\Delta_g f\|_{L^2} \|\Delta_H f\|_{L^2} \geq (\Delta_g f, \Delta_H f)_{L^2} = - \langle df, (\hat{L} - \text{Ric}) df \rangle_{L^2(\nabla^*)}$$

$$= \|\nabla df\|_{L^2(\nabla^*)}^2 + \langle df, \text{Ric} \hat{L} f \rangle_{L^2(\nabla^*)} \geq \frac{1}{n} - \|\Delta_H f\|_{L^2}^2 = K \|df\|_{L^2(\nabla^*)} \|\hat{L} f\|_{L^2(\nabla^*)}.$$
and ultimately

\[ \|\Delta_H f\|_{L^2}^2 \leq n \sqrt{\|\Delta_y f\|_{L^2} \|\Delta_H f\|_{L^2}} (\sqrt{\|\Delta_y f\|_{L^2} \|\Delta_H f\|_{L^2}} + K\|f\|_{L^2}). \]  

By approaching any \( f \in \text{Dom}(\Delta_y) \) by compactly supported functions, we conclude from (3.11) that any such function must satisfy \( \|\Delta_H f\|_{L^2} < \infty \). As a consequence, \( \text{Dom}(\Delta_y) \subseteq \text{Dom}(\Delta_H) \).

Let \( Q_t = e^{t\Delta_y/2} \) and \( P_t = e^{t\Delta_n/2} \) be the semigroups of \( \Delta_y \) and \( \Delta_H \), which exists by the spectral theorem. For any \( f \in \text{Dom}(\Delta_H) \), \( u_t = \Delta_H Q_t f \) is an \( L^2 \) solution of

\[ \left( \frac{\partial}{\partial t} - \frac{1}{2}\Delta_y \right) u_t = 0, \quad u_0 = \Delta_H f. \]

By Lemma 3.9 we obtain \( \Delta_H Q_t f = Q_t \Delta_H f \). Furthermore, for any \( s > 0 \) and \( f \in L^2 \), we know that \( Q_s f \in \text{Dom}(\Delta_y) \subseteq \text{Dom}(\Delta_H) \), and since

\[ \left( \frac{\partial}{\partial t} - \frac{1}{2}\Delta_H \right) Q_s P_t f = 0, \]

it again follows from Lemma 3.9 that \( P_t Q_s f = Q_s P_t f \) for any \( s, t \geq 0 \) and \( f \in L^2 \). The operators consequently spectrally commute, see [35, Chapter VIII.5].

\[ \square \]

Remark 3.11. The results of Lemma 2.1 and Lemma 3.10 do not need the bracket generating assumptions. The result of \( \tilde{L} \) being symmetric is also found in [19, Theorem 2.5.1] for the case when \( \nabla \) and \( \bar{\nabla} \) preserves the metric.

3.6. Proof of Theorem 3.6. We consider the assumptions that \( \delta \mathcal{C} = 0 \) and that the symmetric part \( \text{Ric}^s \) of the Ric is bounded from below. By Lemma 3.7, the anti-symmetric part \( \text{Ric}^a \) is a bounded operator. Furthermore, the operators \( \Delta_y \) and \( \Delta_H \) spectrally commute by Proposition 3.8.

Let \( X_t(x), \tilde{f}_t \) and \( \tilde{Q}_t \) be as in the statement of the theorem. If

\[ N_t = \tilde{Q}_t / \tilde{f}_t^{-1} \alpha(X_t(x)) \]

for an arbitrary \( \alpha \in \Gamma(T^* M) \), then by Itô’s formula

\[ dN_t \overset{\text{loc. in.}}{=} \tilde{Q}_t / \tilde{f}_t^{-1} (\tilde{L} - \text{Ric}) \alpha(X_t(x)) dt \]

where \( \overset{\text{loc. in.}}{=} \) denotes equivalence modulo differential of local martingales. Consider \( L^2(T^* M) \) as the space of \( L^2 \)-one-forms on \( M \) with respect to \( g \). Since \( g \) is complete and \( \text{Ric}^a \) bounded from below, the operator \( \tilde{L} - \text{Ric}^s \) is essentially self-adjoint by Lemma 3.10 and Lemma A.1. Hence, by Lemma A.4, there is a strongly continuous semigroup \( \text{P}_t^{(1)} \) on \( L^2(TM) \) with generator \( (\tilde{L} - \text{Ric}, \text{Dom}(\tilde{L} - \text{Ric}^s)) \) such that

\[ \text{P}_t^{(1)} \alpha(x) = \mathbb{E}[1_{t<\tau(x)} N_t] = \mathbb{E}[1_{t<\tau(x)} \tilde{Q}_t / \tilde{f}_t^{-1} \alpha(X_t(x))]. \]

We want to show that for any compactly supported function \( f \), \( \text{P}_t^{(1)} df = dP_t f \) where \( P_t f(x) = \mathbb{E}[f(X_t(x))1_{t<\tau(x)}] \). Following the arguments in [16, Appendix B.1], we have \( P_t f = e^{t\Delta_n/2} f \) where the latter semigroup is the \( L^2 \)-semigroup defined by the spectral theorem and the fact that \( \Delta_H \) is essentially self-adjoint on compactly supported functions. To this end, we want to show that \( dP_t f \) is contained in the
domain of the generator of \( P_t^{(1)} \). This observation will then imply that \( P_t^{(1)} df = dP_t f \), since \( P_t^{(1)} df \) is the unique solution to
\[
\frac{\partial}{\partial t} \alpha_t = \frac{1}{2} L \alpha_t, \quad \alpha_0 = df,
\]
with values in \( \text{Dom}(\hat{L} - \text{Ric}^s) \) by strong continuity, [20, Chapter II.6].

We will first need to show that \( dP_t f \) is indeed in \( L^2 \). Let \( \Delta_g \) denote the Laplace-Beltrami operator of \( g \), which will also be essentially self-adjoint on compactly supported functions since \( g \) is complete. Denote its unique self-adjoint extension by the same symbol. Since the operators spectrally commute, \( e^{s \Delta_g} e^{t \Delta_H} = e^{t \Delta_H} e^{s \Delta_g} \) for any \( s, t \geq 0 \) which implies \( \Delta_g e^{t \Delta_H} = e^{t \Delta_H} \Delta_g f \) for any \( f \) in the domain of \( \Delta_g \).

In particular,
\[
\langle dP_t f, dP_t f \rangle_{L^2(g^s)} = -\langle \Delta_g P_t f, P_t f \rangle_{L^2(g)} = -\langle P_t \Delta_g f, P_t f \rangle_{L^2} < \infty.
\]

Next, since \( \langle (\hat{L} - \text{Ric}^s) \alpha, \alpha \rangle_{L^2(g^s)} \geq -K \| \alpha \|^2_{L^2(g^s)} \) the domain \( \text{Dom}(\hat{L} - \text{Ric}^s) \) equals the completion of compactly supported one-forms \( \Gamma_c(T^* M) \) with respect to the quadratic form
\[
q(\alpha, \alpha) = (K + 1)(\alpha, \alpha)_{L^2(g)} - \langle (\hat{L} - \text{Ric}^s) \alpha, \alpha \rangle_{L^2(g^s)}
= (K + 1)(\alpha, \alpha)_{L^2(g)} - \langle (\hat{L} - \text{Ric}^s) \alpha, \alpha \rangle_{L^2(g^s)}.
\]

Since \( P_t f \) is in the domain of both \( \Delta_g \) and \( \Delta_H \) for any compactly supported \( f \), we have that for any fixed \( t \), there is a sequence of compactly supported functions \( h_n \) such that \( h_n \to P_t f, \Delta_H h_n \to \Delta_H P_t f \) and \( \Delta_g h_n \to \Delta_g P_t f \) in \( L^2 \). From the latter fact, it follows that \( dh_n \) converges to \( dP_t f \) in \( L^2 \) as well. Furthermore,
\[
q(dh_n, dh_n) = (K + 1)(dh_n, dh_n)_{L^2(g)} - \langle (\hat{L} - \text{Ric}) dh_n, dh_n \rangle_{L^2(g)}
= -(K + 1)\langle h_n, \Delta_g h_n \rangle_{L^2(g)} - \langle d\Delta_H h_n, dh_n \rangle_{L^2(g)}
= -(K + 1)\langle h_n, \Delta_g h_n \rangle_{L^2(g)} + \langle \Delta_H h_n, \Delta_g h_n \rangle_{L^2(g)}
\]
which has a finite limit as \( n \to \infty \). Hence, \( dP_t f \in \text{Dom}(\hat{L} - \text{Ric}^s) \) and \( P_t^{(1)} df = dP_t f \).

Using that \( \langle \text{Ric} \alpha, \alpha \rangle_g \geq -K \| \alpha \|^2_{g^s} \), Gronwall’s lemma and the fact that \( \hat{\nabla} \) preserves the metric means that
\[
|1_{t<\tau(x)} \hat{Q}_t/\tau \alpha(X_t(x))|_{g^s} \leq e^{Kt/2} 1_{t<\tau(x)} \| \alpha \|_{g^s}(X_t(x)).
\]

Hence,
\[
(3.12) \quad |P_t^{(1)} \alpha(x)|_{g^s} \leq e^{Kt/2} P_t \| \alpha \|_{g^s}(x).
\]

We assumed that \( g \) was complete, so we know that there exists a sequence of compactly supported functions \( g_n \) such that \( g_n \uparrow 1 \) and such that \( \| dg_n \|^2_{L^\infty(g^s)} \to 0 \).

Since \( |dP_t g_n|_{g^s} \to 0 \) uniformly by (3.12) and we know that \( P_t g_n \to P_t 1 \), we obtain \( dP_t 1 = 0 \). Hence, we know that \( P_t 1 = 1 \), which is equivalent to \( \tau(x) = \infty \) almost surely.

It is a standard argument to extend the formulas from functions of compact support to bounded functions with \( \| df \|^2_{L^\infty(g^s)} < \infty \).
3.7. Foliations and a counter-example. Let \((M, H, g_H)\) be a sub-Riemannian manifold and let \(g\) be a Riemannian metric taming \(g_H\) and satisfying \(H = 0\) with \(H\) as in (3.4). Write \(V\) for the orthogonal complement of \(H\). Define the Bott connection, by

\[
\hat{\nabla}_Z Z_2 = \text{pr}_H \nabla^g_{\text{pr}_H Z_1} \text{pr}_H Z_2 + \text{pr}_V \nabla^g_{\text{pr}_V Z_1} \text{pr}_V Z_2
\]

where \(\nabla^g\) denote the Levi-Civita connection. Its torsion \(\hat{T} := T^\nabla\) equals \(\hat{T} = -\mathcal{R} - \mathcal{R}\) and \(\mathcal{R} = 0\) is equivalent to requiring \(H = 0\). Since \(\hat{\nabla}\) is compatible with the metric, we have

\[
\hat{\nabla}_Z = \nabla^g_Z + \frac{1}{2} \hat{T} + \frac{1}{2} \hat{T}^* Z, \quad \hat{T}_Z(A) = T(Z, A).
\]

If \(\zeta\) and \(\nabla\) are as in (3.6) and (3.7), respectively, then

\[
\zeta(v_1, v_2, v_2) = \mathcal{L}_{\hat{T}}(v_1, v_2, v_3)_g, \quad \text{and} \quad \nabla_Z = \nabla_Z + \hat{T}^* Z.
\]

The connection \(\hat{\nabla}\) does not have skew-symmetric torsion; however, it does have the advantage that \(\nabla A B\) is independent of \(g|V\) if either \(A\) or \(B\) takes its values in \(H\), see [23, Section 3.1].

3.7.1. Totally geodesic, Riemannian foliations. Assume that \(\mathcal{R} = 0\), i.e. assume that the orthogonal complement \(V\) of \(H\) is integrable. Let \(F\) be the corresponding foliation of \(V\) that exists from the Frobenius theorem. We have the following way of interpreting the condition \(H = 0\). The tensor \(H(\text{pr}_V \cdot, \text{pr}_V \cdot)\) equals the second fundamental form of the leaves, i.e. \(\text{pr}_H \nabla^g_Z W = H(Z, W)\) for any \(Z, W \in \Gamma(V)\). Hence, \(H(\text{pr}_V \cdot, \text{pr}_V \cdot) = 0\) is equivalent to the leaves of \(F\) being totally geodesic immersed submanifolds. On the other hand, the condition \(0 = -2\langle H(A, A), Z \rangle = (\mathcal{L}_Z g)(A, A)\) for any \(A \in \Gamma(H)\), \(Z \in \Gamma(V)\) is the definition of \(F\) being a Riemannian foliations. Locally, such a foliation \(F\) consists of the fibers of a Riemannian submersion. In other words, every \(x_0 \in M\) has a neighborhood \(U\) such that there exists a surjective submersion between two Riemannian manifolds, satisfying

\[
\pi : (U, g|_U) \to (\check{M}_U, \check{g}_U),
\]

satisfying

\[
\pi_* \circ H|_U \oplus \ker \pi_* = F|_U = \{ \pi^{-1}(\check{x}) : \check{x} \in \check{M}_U \}
\]

and that \(\pi_* : H|_U \to T_{\pi(x)} \check{M}_U\) is an isometry for every \(x \in U\).

The following result is found in [17] for totally geodesic Riemannian foliations. Let \(X_t(\cdot)\) be a stochastic flow with generator \(\frac{1}{2} \Delta_H\) where the latter is define relative to the volume density of \(g\).

**Theorem 3.12.** If \((M, g)\) is a stochastically complete Riemannian manifold, then \(X_t(x)\) has infinite lifetime.

In particular, if the Riemannian Ricci curvature \(\text{Ric}_g\) is bounded from below, \(X_t(x)\) has infinite lifetime. We want to compare this result using the entire Riemannian geometry with our result using \(\text{Ric}(\hat{\nabla})\), an operator only defined by taking the trace over horizontal vectors. For this special case, it turns out that \(\text{Ric}_g\) being bounded from below is actually a weaker condition than \(\text{Ric}(\hat{\nabla})\) being bounded from below.
Proposition 3.13. Let $(M, H, g_H)$ be a sub-Riemannian manifold with $H$ is bracket-generating. Let $\mathcal{F}$ be a foliation of $M$ corresponding to an integrable subbundle $V$ such that $TM = H \oplus V$. Let $g$ be any Riemannian metric taming $g_H$ such that $H = 0$, making $\mathcal{F}$ a totally geodesic Riemannian foliation. Assume finally that $g$ is complete. For $x \in M$, let $F_x$ denote the leaf of the foliation $\mathcal{F}$ containing $x$. Write $\text{Ric}_{F_x}$ for the Ricci curvature tensor of $F_x$.

(a) For any $x, y \in M$, there exist neighborhoods $x \in U_x \subseteq F_x$ and $y \in U_y \subseteq F_y$, and an isometry

$$\Phi : U_x \to U_y, \quad \Phi(x) = y.$$ 

As a consequence, if we define $\text{Ric}_\mathcal{F}$ such that

$$\text{Ric}_\mathcal{F}(v, w) = \text{Ric}_{F_x}(\text{pr}_V v, \text{pr}_V w), \quad \text{for any } v, w \in T_x M,$$

then $\text{Ric}_\mathcal{F}$ is bounded.

(b) Let $\text{Ric}_g$ be the Ricci curvature of the Riemannian metric $g$. Let $\nabla$ be defined as in (3.7). Then

$$\text{Ric}_g(v, v) = \text{Ric}(\nabla)(uv)(v) + \frac{1}{2} \sum_{i=1}^{n} \|\mathcal{R}(A_i, v)\|^2_g + \text{Ric}_\mathcal{F}(\text{pr}_V v, \text{pr}_V v).$$

(3.15) In particular, $\text{Ric}_g$ has a lower bound if $\text{Ric}(\nabla)$ has a lower bound.

Before presenting the proof we need the next lemma. Let $(M, g)$ be a complete Riemannian manifold and let $\mathcal{F}$ be a Riemannian foliation with totally geodesic leaves. Let $V$ be the integrable subbundle of $TM$ corresponding to $\mathcal{F}$ and define $H$ as its orthogonal complement. Write $n$ for the rank of $H$ and $\nu$ for the rank of $V$.

Define

$$O(n) \to O(H) \overset{p}{\to} M$$

as the orthonormal frame bundle of $H$. Introduce the principal connection $E$ on $p$ corresponding to the restriction of $\nabla$ to $H$. In other words, $E$ is the subbundle of $TO(H)$ satisfying $TO(H) = E \oplus \ker p_\nu$, $E_{\phi \cdot a} = E_{\phi \cdot a}$, $\phi \in O(H)$, $a \in O(n)$ and defined such that a curve $\phi(t)$ in $O(H)$ is tangent to $E$ if and only if the frame is $\nabla$-parallel along $\phi(t)$. For any $u = (u_1, \ldots, u_n) \in \mathbb{R}^n$, define $A_u$ as the vector field on $O(H)$ taking values in $E$ uniquely determined by the property

$$p_*A_u(\phi) = \sum_{j=1}^{n} u_j \phi_j, \quad \text{for any } \phi = (\phi_1, \ldots, \phi_n) \in O(H).$$

For any $\phi \in O(H)_{x}$, define $F_\phi$ as all points that can be reached from $\phi$ by an $E$-horizontal lift of a curve in $F_x$ starting in $x$. We then have the following result, found in [17], see also [40, Chapter 10] and [32].

Lemma 3.14. The collection $\mathcal{F} = \{F_\phi : \phi \in O(H)\}$ gives a foliation of $O(H)$ with $\nu$-dimensional leaves such that for each $\phi \in O(n)$ the map

$$p|_{\hat{F}_\phi} : \hat{F}_\phi \to F_{p(\phi)}$$

is a cover map. Furthermore, giving each leaf of $\mathcal{F}$ a Riemannian structure by pulling back the metric from the leaves of $\mathcal{F}$, then for any $u \in \mathbb{R}^n$ and $t \in \mathbb{R}$, the flow $\Psi_u(t) = e^{tA_u}$ maps $F_\phi$ onto $F_{\Psi_u(t)(\phi)}$ isometrically for each $\phi \in O(H)$.

Note that the reason for using the connection $\nabla$ in the definition of $\hat{F}$, is that $R_{\nu}(Z, W)A = 0$ for any $Z, W \in \Gamma(V)$ and $A \in \Gamma(H)$.
Proof of Proposition 3.13. (a) For any \( x \in M \), choose a fixed element \( \phi_0 \) in \( O(H)_x \). Define
\[ O_{\phi_0} = \{ \Psi_{u_k}(t_k) \circ \cdots \circ \Psi_{u_1}(t_1)(\phi) : t_j \in \mathbb{R}, u_j \in \mathbb{R}^n, k \in \mathbb{N} \}. \]
Clearly, by definition, for any \( \phi \in O_{\phi_0} \), there is an isometry \( \hat{\Phi} : \hat{F}_{\phi_0} \to \hat{F}_{\phi} \) such that \( \hat{\Phi}(\phi_0) = \phi \).

Consider the vector bundle \( \hat{H} = \text{span}\{ \hat{A}_u : u \in \mathbb{R}^n \} \) and define
\[ \text{Lie}_\phi \hat{H} := \text{span}\{ [B_1, [B_2, \ldots, [B_{k-1}, B_k]] \ldots ]_{[\phi]} : B_j \in \Gamma(\hat{H}), k \in \mathbb{R} \} \]
\[ = \text{span}\{ [\hat{A}_{u_1}, [\hat{A}_{u_2}, \ldots, [\hat{A}_{u_{k-1}}, \hat{A}_{u_k}]] \ldots ]_{[\phi]} : u_j \in \mathbb{R}^n, k \in \mathbb{R} \}, \]
for any \( \phi \in O(H) \). By the Orbit Theorem, see e.g. [2, Chapter 5], \( O_{\phi_0} \) is an immersed submanifold of \( O(H) \), and furthermore,
\[ \text{Lie}_\phi \hat{H} \subseteq T_\phi O_{\phi_0}, \quad \text{for any } \phi \in O_{\phi_0}. \]
Furthermore, since \( p_x \text{Lie}_\phi \hat{H} = H \) and since \( H \) is bracket-generating, we have that \( p_x \text{Lie}_\phi \hat{H} = T_{p(\phi)}M \). It follows that \( p(O_{\phi_0}) = M \). Hence, for any \( y \in M \), there is an isometry \( \hat{\Phi} : \hat{F}_{\phi_0} \to \hat{F}_\phi \) with \( \hat{\Phi}(\phi_0) = \phi \) for some \( \phi \in O(H)_y \). As a consequence, there is a local isometry \( \hat{\Phi} \) taking \( x \) to \( y \).

(b) Note that if \( R^g \) is the curvature of the Levi-Civita connection, then
\[ \langle R^g(Z_1, Z_2)B_1, B_2 \rangle_g = \langle R(\nabla Z_1, Z_2)B_1, B_2 \rangle_g + \frac{1}{2} \langle \nabla_{Z_1} \zeta(Z_2, B_1, B_2) \rangle_g \]
\[ - \frac{1}{2} \langle \nabla_{Z_2} \zeta(Z_1, B_1, B_2) \rangle_g - \frac{1}{2} \langle T(Z_1, Z_2), T(B_1, B_2) \rangle_g \]
\[ - \frac{1}{4} \langle T(Z_1, B_2), T(Z_2, B_1) \rangle_g + \frac{1}{4} \langle T(Z_1, B_1), T(Z_2, B_2) \rangle_g \]
for \( Z_j, B_j \in \Gamma(TM) \). Since all the leaves of the foliation are totally geodesic, if \( R^\varphi \) denotes the curvature tensor along the leaves, then \( \langle R^g(Z_1, Z_2)B_1, B_2 \rangle = \langle R^\varphi(Z_1, Z_2)B_1, B_2 \rangle \) whenever all vector fields take values in \( V \). We compute using any local orthonormal bases \( A_1, \ldots, A_n \) and \( Z_1, \ldots, Z_\nu \) of \( H \) and \( V \), respectively,
\[ \text{Ric}_g(v, v) = \sum_{i=1}^n \langle R^g(A_i, v)A_i \rangle_g + \sum_{s=1}^\nu \langle R^g(Z_s, \text{pr}_H v) \text{pr}_H v, Z_s \rangle_g \]
\[ + 2 \sum_{s=1}^\nu \langle R^g(Z_s, \text{pr}_V v) \text{pr}_H v, Z_s \rangle_g + \sum_{s=1}^\nu \langle R^g(Z_s, \text{pr}_V v) \text{pr}_V v, Z_s \rangle_g \]
\[ = \text{Ric}(\nabla)(v)(v) + \frac{1}{2} \sum_{i=1}^n \|\text{R}(A_i, v)\|_g^2 + \text{Ric}_V(\text{pr}_V v, \text{pr}_V v). \]
The result now follows from (a). \( \square \)

Remark 3.15. (a) Let \( g \) be any metric taming \( g_H \) such that \( H = 0 \). Write \( V \) for the orthogonal complement of \( H \). Then for any \( \varepsilon > 0 \), the scaled Riemannian metric
\[ g_\varepsilon(v, w) = g(\text{pr}_H v, \text{pr}_H w) + \frac{1}{\varepsilon} g(\text{pr}_V v, \text{pr}_V w), \]
also tames \( g_H \) and satisfies \( H = 0 \). Since \( \nabla_A B \) is independent of \( g|V \) whenever at least one of the vector fields takes values only in \( H \), it behaves better with
respect to the scaled metric. Such scalings of the extended metric are important for the sub-Riemannian curvature-dimension inequality, see [10, 7, 9, 11, 23, 24].

(b) If $\mathcal{R} = 0$ then we have that $\text{tr}_H(\nabla_x \mathcal{R})(\cdot, \cdot) = \text{tr}_H(\nabla_x \mathcal{R})(\cdot, \cdot)$. If this map vanishes, i.e. if $\text{Ric}(\nabla)$ is a symmetric operator, then $H$ is said to satisfy the Yang-Mills condition. One may consider subbundles $H$ satisfying this condition as locally minimizing the curvature $\mathcal{R}$. See [24, Appendix A.4] for details.

3.7.2. Regular foliations. We will give a short remark on the case in Section 3.7.1 where the foliation is also regular, i.e. when there is a global Riemannian submersion $\pi : (M, g) \to (\hat{M}, \hat{g})$ with the foliation $\mathcal{F} = \{F_y = \pi^{-1}(y) : y \in \hat{M}\}$. We can rewrite (3.15) as

$$\text{Ric}_y(v, v) = \text{Ric}(\nabla)(hv)v - \frac{3}{2} \|\mathcal{R}(v, \cdot)\|_{g^{\otimes 2}}^2 + \text{Ric}_{\mathcal{F}}(\text{pr}_V v, \text{pr}_V v).$$

Hence, requiring that $\text{Ric}(\nabla)$ is bounded from below is even weaker than requiring this for $\text{Ric}_y$. This weaker condition is a sufficient requirement for infinite lifetime for the case of regular foliations.

To prove this, we need a result in [27]. Fix a point $y_0 \in \hat{M}$ and let $\sigma : [0, 1] \to \hat{M}$ be a smooth curve with $\sigma(0) = y_0$. Define $F = F_{y_0}$ and write $\sigma^t$ for the $H$-horizontal lift of $\sigma$ starting at $x \in F$. Then the map

$$\Psi_{\sigma(t)} : F \to F_{\sigma(t)}, \quad \Psi_{\sigma(t)}(x) = \sigma^t(t),$$

is an isometry, so all leaves of $\mathcal{F}$ are isometric. Write $G$ for the isometry group of $F$ and $Q_y$ for the space of isometries $q : F \to F_y$. Then $Q = \bigsqcup_{y \in \hat{M}} Q_y$ can be given a structure of a principal bundle, such that

$$p : Q \times F \to \hat{M} \cong (Q \times F)/G, \quad (q, z) \mapsto q(z).$$

In the above formula, $\phi \in G$ acts on $F$ on the right by $z \cdot \phi = \phi^{-1}(z)$. Finally, if we define

$$E = \left\{ \frac{d}{dt} \Psi_{\sigma(t)} \circ \phi : \sigma \in C^\infty([0, 1], \hat{M}), \sigma(0) = y_0, \phi \in G, t \in [0, 1] \right\} \subseteq TQ,$$

then $E$ is a principal connection on $Q$ and $p_* E = H$.

One can verify that if $Y_t(y)$ is the Brownian motion in $\hat{M}$ starting at $y \in \hat{M}$ with horizontal lift $\tilde{Y}_t(q)$ to $q \in Q_y$ with respect to $E$, then $X_t(x) = p(\tilde{Y}_t(q), z)$ is a diffusion in $\hat{M}$ with infinitesimal generator $\frac{1}{2} \Delta_H$ starting at $x = p(q, z)$. Hence, if $Y_t(y)$ has infinite lifetime, so does $X_t(x)$ as a process and its horizontal lifts to principal bundles have the same lifetime by [36]. Since a lower bound of $\text{Ric}(\nabla)$ is equivalent to a lower bound of the Ricci curvature of $\hat{M}$ by [23, Section 2], this is a sufficient condition for infinite lifetime of $X_t(x)$.

The above argument does not depend on $H$ being bracket-generating. However, in the case of $H$ bracket-generating, $F$ is a homogeneous space by a similar argument to that of the proof of Proposition 3.13.

3.7.3. A counter-example. We will give an example showing that the assumption $\mathcal{R} = 0$ is essential for the conclusion of Proposition 3.13.

Example 3.16. Consider $\mathfrak{su}(2)$ as the Lie algebra spanned by elements $A_1, A_2$ and $A_3$ with bracket-relations

$$[A_1, A_2] = A_3, \quad [A_3, A_1] = A_2, \quad [A_2, A_3] = A_1.$$
Let $G$ be any connected Lie group with Lie algebra $\mathfrak{su}(2)$. Denote the left invariant vector fields and their corresponding elements in the Lie algebra by the same symbol. Let $\varphi : G \to \tilde{G}$ be a Lie group isomorphism to another copy $\tilde{G}$ of $G$. Use this to define vector fields on $G \times \tilde{G}$ by

$$A_k'(x, y) = A_k(x) + \varphi_* A_k(\varphi^{-1}(y)), \quad A_k''(x, y) = A_k(x) - \varphi_* A_k(\varphi^{-1}(y)),$$

for any $(x, y) \in G \times \tilde{G}$. Observe that $[A_i, A_j] = A_k$ implies that

$$[A_i', A_j'] = A_k', \quad [A_i'', A_j''] = A_k', \quad [A_i'', A_j'''] = A_k''.$$

Consider $\mathbb{R}$ with coordinate $c$. Define a manifold $M = G \times \tilde{G} \times \mathbb{R}$. Let $f$ be an arbitrary smooth function on $M$ that factors through the projection to $\mathbb{R}$, i.e. $f(x, y, c) = f(c)$ for $(x, y, c) \in G \times \tilde{G} \times \mathbb{R}$. Write $\partial_\ell f$ simply as $f'$. Introduce the vector fields $Z_j$, $j = 1, 2, 3$ on $M$ such that

$$Z_1 = e^f A_1', \quad Z_2 = e^f A_2', \quad Z_3 = e^f A_3'.$$

Define a Riemannian metric $g$ on $M$ such that $Z_1, Z_2, Z_3, A_1', A_2', A_3'$, $\partial_\ell$ form an orthonormal basis. Define a sub-Riemannian manifold $(M, H, g_H)$ such that $H$ is the span of $Z_1, Z_2, Z_3$ and $\partial_\ell$ with $g_H$ as the restriction of $g$ to this bundle. If we define $H$ and $C$ as in respectively (3.4) and (3.9), then we have $H = 0$ and $C = 0$, even though $\mathcal{R} \neq 0$. If $\nabla$ is as in (3.7), then $\text{Ric}(\nabla)$ is given by

$$\text{Ric}(\nabla) := \begin{cases} \frac{\partial Z_1 \mapsto (f'' - e^{2f}(e^{2f} - 1) - 3(f')^2) \partial Z_1}, \\ \frac{\partial Z_2 \mapsto (f'' - 2e^{2f}(e^{2f} - 1) - 3(f')^2) \partial Z_2}, \\ \frac{\partial Z_3 \mapsto (f'' - e^{2f}(e^{2f} - 1) - 3(f')^2) \partial Z_3}, \\ \frac{\partial \ell \mapsto 2(f'' - (f')^2) \partial \ell}. \end{cases}$$

However, one can also verify that if $\text{Ric}_g$ is the Ricci curvature of $g$, then

$$\text{Ric}_g(A_2', A_2') = 2 - e^{-f}.$$

Hence, if $f'$ and $f''$ are bounded and $f$ is bounded from above but not from below, then $\text{Ric}(\nabla)$ has a lower bound, but not $\text{Ric}_g$. We may for example take $f(c) = -c \tan^{-1} c$.

4. **Torsion and integration by parts**

4.1. **Torsion and integration by parts.** For a function $f \in C^\infty(M)$ on a sub-Riemannian manifold define the horizontal gradient $\nabla^H f = \sharp^H df$. The fact that the parallel transport $//_t$ in Theorem 3.6 does not preserve the horizontal bundle, makes it difficult to bound $\nabla^H P_t f$ by terms only involving the horizontal part of the gradient of $f$ and not the full gradient. We therefore give the following alternative stochastic representation of the gradient.

Let $(M, g^H)$ be a sub-Riemannian manifold and let $\nabla$ be compatible with $g^H$. Let $g$ be a Riemannian metric taming $g^H$ and assume that $\nabla$ is compatible with $g$ as well. Introduce a zero order operator

$$(4.1) \quad \mathcal{A}(\alpha) := \text{Ric}(\nabla)\alpha - \alpha(\text{tr}_H(\nabla_x T^\nabla)(x, \cdot)) - \alpha(\text{tr}_H T^\nabla(\cdot, T^\nabla(x, \cdot))) = \text{Ric}(\nabla)\alpha - \alpha(\text{tr}_H T^\nabla(\cdot, T^\nabla(x, \cdot))).$$

Let $X_t(\cdot)$ be the stochastic flow of $\frac{1}{2} L(\nabla)$ with explosion time $\tau(\cdot)$. Write $//_t = //_t(x) : T_x M \to T_{X_t(x)} M$ for parallel transport with respect to $\nabla$ along $X_t(x)$. 
Observe that this parallel transport along $\nabla$ preserves $H$ and its orthogonal complement. Let $W_t = W_t(x)$ denote the anti-development of $X_t(x)$ with respect to $\nabla$ which is a Brownian motion in $(H_x, \langle \cdot, \cdot \rangle_{gH(x)})$.

**Theorem 4.1.** Assume that $\tau(x) = \infty$ a.s. for any $x \in M$ and that for any $f \in C^\infty_0(M)$ with bounded gradient, we have $\sup_{t \in [0,1]} \|dP_tf\|_{L^\infty(g^* \otimes g)} < \infty$. Furthermore, assume that $|T^H\nabla_{j^* g^* \otimes g} < \infty$ and that $\mathcal{A}$ is bounded from below. Define stochastic processes $Q_t = Q_t(x)$ and $U_t = U_t(x)$ taking values in $\operatorname{End} T^*_x M$ as follows:

$$\frac{d}{dt} Q_t = -\frac{1}{2} Q_t \mathcal{A}_{/t}, \quad Q_0 = \operatorname{id},$$

resp.

$$U_t\alpha(v) = \int_0^t \alpha T^H_{//t}(dW_s, Q^*_1 v), \quad T^H_{//t}(v, w) = \|t^{-1}T(\|v, \|_t w).$$

Then for any $f \in C^\infty_0(M)$,

$$dP_t f(x) = E \left[ (Q_t + U_t)/t^{-1} df(X_t(x)) \right]. \quad (4.2)$$

For a geometric interpretation of $\mathcal{A}$ for different choices of $\nabla$, see Section 4.2. The equality (4.2) allows us to choose the connection $\nabla$ convenient for our purposes and gives us a bound for the horizontal gradient on Carnot groups in Section 4.3.

For the proof of this result, we rely on ideas from [16]. A multiplication $m$ of $T^*M$ is a map $m : T^*M \otimes T^*M \to T^*M$. Corresponding to a multiplication and a connection $\nabla$, we have a corresponding first order operator

$$D^m \alpha = m(\nabla \alpha).$$

**Lemma 4.2.** Let $\nabla$ be a connection compatible with $g_H$ and with torsion $T$. Define $L = L(\nabla)$, $\operatorname{Ric} = \operatorname{Ric}(\nabla)$ and $T = T^\nabla$. Then for any $f \in C^\infty(M)$,

$$Ldf - dLf = -2D^m df + \mathcal{A}(df),$$

where $m(\beta \otimes \alpha) = \alpha(T^H(\beta, \cdot))$ and

$$\mathcal{A}(\alpha) = \operatorname{Ric}(\alpha) - \alpha(\operatorname{tr_H}(\nabla_x T)(x, \cdot)) - \alpha(\operatorname{tr_H} T(x, T(x, \cdot))). \quad (4.3)$$

**Proof.** Recall that if $\nabla$ is the adjoint of $\nabla$ and $\tilde{L} = L(\nabla)$, then

$$(Ldf - dLf) = \operatorname{Ric} df.$$

The result now follows from Lemma 3.3 and the fact that for any $A \in \Gamma(H)$,

$$\nabla_A \nabla = \nabla_A + \kappa(A),$$

where $\kappa(A) = \alpha(T(A, \cdot)) = m(\beta A \otimes \alpha)$. \hfill \Box

**Proof of Theorem 4.1.** Let $x \in M$ be fixed. To simplify notation, we shall write $X_t(x)$ simply as $X_t$. Define $\parallel_{/t}$ as parallel transport with respect to $\nabla$ along $X_t$. Define $Q_t$ as in Theorem 4.1. For any $S > 0$, consider the stochastic process on $[0, S]$ with values in $T^*_x M$,

$$N_t = \parallel_{/S}^{-1} dP_{S-t} f(X_t).$$

By Lemma 4.2 and Itô’s formula

$$dN_t = \parallel_{/S}^{-1} \nabla_{/t} dW_t dP_{S-t} f(X_t) - \parallel_{/S}^{-1} D^m dP_{S-t} f(X_t) dt + \frac{1}{2} \parallel_{/S}^{-1} \mathcal{A}(dP_{S-t} f(X_t)) dt,$$
and so
\[ dQ_t N_t = Q_t / t^{-1} \nabla / t dW_t dP_{S-t} f(X_t) - Q_t / t^{-1} D^m dP_{S-t} f(X_t) dt. \]

Since \( W_t \) is a Brownian motion in \( H_x \) and \( / t \) preserves \( H \) and its inner product, the differential of the quadratic covariation equals
\[ d[U_t, N_t] = Q_t / t^{-1} D^m dP_{S-t} f(X_t) dt. \]

Hence, \((Q_t + U_t)N_t\) is a local martingale which is a true martingale from our assumptions. The result follows. \(\Box\)

4.2. Geometric interpretation. We will look at some specific examples to interpret Theorem 4.1 and the zero order operator \(\mathcal{A}\) in (4.3).

4.2.1. Totally geodesic Riemannian foliation and its generalizations. Assume that condition (3.5) holds, so that we are in the case of Section 3.2. Define \(\nabla\) as in (3.7) and let \(\nabla\) be as in (3.13). Recall that its torsion \(\tilde{T}\) equals \(\tilde{T} = -R - R\) and that \(\nabla_Z = \nabla_Z + \tilde{T}^z Z\). Using Lemma 3.7, we obtain
\[
\langle \mathcal{A} \alpha, \beta \rangle = \langle \text{Ric}(\nabla) \text{pr}_H^* \alpha, \text{pr}_H^* \beta \rangle_{g^*} + \langle \text{Ric}(\nabla) \text{pr}_H^* \alpha, \text{pr}_H^* \beta \rangle_{g^*}
- \alpha(\text{tr}_H (\nabla \otimes T)(x, \cdot, \cdot)) - \langle \alpha, \text{tr}_H (T(\nabla \otimes T)(x, \cdot, \cdot)) \rangle_g
= \langle \text{Ric}(\nabla) \text{pr}_H^* \alpha, \text{pr}_H^* \beta \rangle_{g^*} + 2 \langle \alpha, \text{tr}_H (T(\nabla \otimes T)(x, \cdot, \cdot)) \rangle_g
= \langle \text{Ric}(\nabla) \text{pr}_H^* \alpha, \text{pr}_H^* \beta \rangle_{g^*} + 2 \langle \alpha, \text{tr}_H (T(\nabla \otimes T)(x, \cdot, \cdot)) \rangle_g.
\]

In particular, \(\mathcal{A}\) does not depend on \(g[V]\).

4.2.2. Lie groups of polynomial growth. Let \(G\) be a connected Lie group with unit \(1\) of polynomial growth. Consider a subspace \(\mathfrak{h}\) that generates all of \(\mathfrak{g}\). Equip \(\mathfrak{h}\) with an inner product and define a sub-Riemannian structure \((\mathcal{H}, g_H)\) by left translation of \(\mathfrak{h}\) and its inner product. Let \(g\) be any left invariant metric taming \(g_H\). Let \(\nabla\) be the connection defined such that any left invariant vector field on \(G\) is \(\nabla\)-parallel. Then \(\nabla\) is compatible with \(g_H^*\) and \(g\). Let \(X_t(\cdot)\) be the stochastic flow of \(\frac{1}{\sqrt{t}} L(\nabla)\), which has infinite lifetime by [25]. Furthermore, \(\|dP_t f\|_{L^\infty(g^*)} < \infty\) for any bounded \(f \in C^\infty_b (M)\) by [39]. Hence we can use Theorem 4.1.

Let \(l_x : G \to G\) denote left multiplication on \(G\) and write \(x \cdot v := dl_x v\). Notice that since we have a left invariant system, \(X_t(x) = x \cdot X_t(1) = x \cdot X_t\). Furthermore, parallel transport with respect to \(\nabla\) is simply left translation so
\[
/ t(x)v = (x \cdot X_t \cdot x^{-1}) \cdot v.
\]

If \(W_t(x)\) is the anti-development of \(X_t(x)\) with respect to \(\nabla\) then
\[
W_t(x) = x \cdot W_t(1) = x \cdot W_t.
\]

As \(\nabla\) is a flat connection and since
\[
T_{\nabla}(A_1, A_2) = -[A_1, A_2],
\]
for any pair of left invariant vector fields \(A_1\) and \(A_2\), we have that \(\mathcal{A}\) in (4.3) equals
\[
\mathcal{A} = -\alpha(\text{tr}_H (T(\nabla \otimes T)(x, \cdot, \cdot))).
\]

In other words, if we define a map \(\psi : \mathfrak{g} \to \mathfrak{g}\) by
\[
\psi = \text{tr}_H \text{ad}(x) \text{ad}(x),
\]
then
\[
\mathcal{A} \alpha = -l^*_x \psi l^*_x \alpha, \quad \alpha \in T^*_x M.
\]
Both $\mathcal{A}$ and $T^\nabla$ are bounded in $g$. Hence, we can conclude that for any $v \in \mathfrak{g}$ and $x \in G$,
\[
dP_t f(x \cdot v) = \mathbb{E} \left[ df \left( (x \cdot X_t) \cdot \left( Q^*_t v + \int_0^t \text{ad}(Q^*_s v) dW_s \right) \right) \right]
\]
where
\[
Q_t = \exp \left( -t \psi^* / 2 \right).
\]
Note that $Q_t$ is deterministic in this case.

4.3. Carnot groups and a gradient bound. Let $G$ be a simply connected nilpotent Lie group with Lie algebra $\mathfrak{g}$ and identity $1$. Assume that there exists a stratification $\mathfrak{g} = \mathfrak{g}_1 \oplus \cdots \oplus \mathfrak{g}_k$ into subspaces, each of strictly positive dimension, such that $[\mathfrak{g}_i, \mathfrak{g}_j] = \mathfrak{g}_{i+j}$ for any $j \geq 1$ with convention $\mathfrak{g}_{k+1} = 0$. Write $\mathfrak{h} = \mathfrak{g}_1$ and choose an inner product on this vector space. Define the sub-Riemannian structure $(\mathcal{H}, g_{\mathcal{H}})$ on $G$ by left translation of $\mathfrak{h}$ and its inner product. Then $(G, \mathcal{H}, g_{\mathcal{H}})$ is called a Carnot group of step $k$. Carnot groups are important as they are the analogue of Euclidean space in Riemannian geometry, in the sense that any sub-Riemannian manifold has a Carnot group as its metric tangent cone at points where the horizontal bundle is equiregular. See [12] for details and the definition of equiregular.

Let $(\mathcal{H}, H, g_{\mathcal{H}})$ be a Carnot group with $n = \text{rank } H$. Let $\Delta_H$ be defined with respect to left Haar measure on $G$, which equals the right Haar measure since nilpotent groups are unimodular. Consider the commutator ideal $\mathfrak{k} = [\mathfrak{g}, \mathfrak{g}] = \mathfrak{g}_2 \oplus \cdots \oplus \mathfrak{g}_k$ with corresponding normal subgroup $K$. Define the corresponding quotient map
\[
\pi : G \to G/K \cong \mathfrak{h},
\]
and write $|\pi| : x \mapsto |\pi(x)|_{g_{\mathcal{H}}(1)}$.

It is known from [15] and [31] that for each $p \in (1, \infty)$, there exists a constant $C_p$ such that $[\nabla^H P_t]_{g_{\mathcal{H}}} \leq C_p (P_t [\nabla^H f]_{g_{\mathcal{H}}})^{1/p}$ pointwise for any $f \in C^\infty(M)$. We want to give a more explicit form of constants satisfying this inequality.

**Theorem 4.3.** Let $\psi$ be defined as in (4.4) and assume that $\psi|\mathfrak{h} = 0$. Let $p_n(x, y)$ denote the heat kernel of $\Delta_H$ and define $\varrho(x) = p_1(1, x)$. Define a probability measure $\mathbb{P}$ on $M$ by $d\mathbb{P} = \varrho d\mu$.

(a) Consider the function $\varrho(x) = n + |\pi|([x]_{\mathfrak{g}_{\mathcal{H}}(1)})$ for any $p \in (1, \infty]$,
\[
C_p = \left( \int_G \varrho(y) \cdot \varrho^q(y) d\mu(y) \right)^{1/q}, \quad \frac{1}{p} + \frac{1}{q} = 1.
\]
Then the constants $C_p$ are all finite and for any $x \in G$ and $t \geq 0$, we have
\[
[\nabla^H P_t]_{g_{\mathcal{H}}}(x) \leq C_p [P_t [\nabla^H f]_{g_{\mathcal{H}}(x)}]^{1/p}, \quad f \in C^\infty(M)
\]
Furthermore, $C_2 < n + (nQ - 2 \text{Cov}_{\varrho}([|\pi|^2, \log \rho]))^{1/2}$ where $\text{Cov}_{\varrho}$ is the covariance is with respect to $\mathbb{P}$.

(b) Let $Q$ be the homogeneous dimension of $G$,
\[
Q = \sum_{j=1}^k j (\text{rank } \mathfrak{g}_j).
\]
For any smooth function $f \in C^\infty(G)$ and $t \geq 0$, we have

$$P_t f^2 - (P_t f)^2 \leq t C_2^2 P_t|\nabla^H f|^2_{g_H}$$

with $C_2$ as in Eq. (4.5).

Let $g$ be a left invariant metric on $G$ taming $g_H$. Let $\nabla$ be the connection on $M$ defined such that all left invariant vector fields are parallel. As

$$\beta(v) = \text{tr} T^\nabla(v, \cdot) = 0,$$

we have that $L(\nabla)^* = L(\nabla)$ by Lemma 2.1. Furthermore, if $A_1, \ldots, A_n$ is a basis of $\mathfrak{g}$, then $L(\nabla)f = \sum_{i=1}^n A_i^2 f$ by [1]. Before passing to our desired inequalities, we review some facts about Carnot groups.

Let $X_t := X_t(1)$ be a $\frac{1}{2}\Delta_H$-diffusion starting at the identity 1 and let $//_t$ denote the corresponding parallel transport along $X_t$ with respect to $\nabla$. Let $\pi: G \to \mathfrak{h}$ denote the quotient map.

(i) For any $v, w \in H$ we have $(v, w)_{g_H} = \langle \pi_* v, \pi_* w \rangle_{g_H(1)}$. Hence we can consider our sub-Riemannian structure as having been obtained by choosing a principal Ehresmann connection $H$ on $\pi$ and lifting the metric on $\mathfrak{h}$. It follows by [23, Section 2] that $\Delta_H$ is the horizontal lift of the Laplacian of $(\mathfrak{h}, \langle \cdot, \cdot \rangle_{g_H(1)})$ and so we have that $W_t = \pi(X_t)$ is a Brownian motion in the inner product space $\mathfrak{h}$. Since

$$\pi_* v = \text{pr}_\mathfrak{h} x^{-1} \cdot v, \quad v \in T_x G,$$

we can identify $W_t$ with the anti-development of $X_t$.

(ii) Since $\Delta_H$ is left invariant, $X_t(x) := x \cdot X_t$ is a $\frac{1}{2}\Delta_H$-diffusion starting at $x$, and $P_t f(x) = P_t(f \circ l_x)(1)$ where $l_x$ denotes left translation. In particular, if $\varrho_t(x) := p_t(1, x)$ then

$$p_t(x, y) = \varrho_t(x^{-1} y).$$

(iii) Since the Lie algebra $\mathfrak{g}$ has a stratification, for any $s > 0$, the map $(\text{Dil}_s)_*: \mathfrak{g} \to \mathfrak{g}$ is given by

$$\text{Dil}_s A \in \mathfrak{g}_j \mapsto s^j A.$$  

is a Lie algebra automorphism. It correspond to a Lie group automorphism $\text{Dil}_s$ of $G$ since $G$ is simply connected. These automorphisms are called \textit{dilations}. It can be verified that if $A \in \mathfrak{g}_j$ and we use the same symbol for the corresponding left invariant vector field then

$$A(f \circ \text{Dil}_s) = s^j (Af) \circ \text{Dil}_s.$$
(iv) As a consequence of Item (iii) we have
\[ \Delta_H (f \circ \text{Dil}_s) = s^2 (\Delta_H f) \circ \text{Dil}_s, \]
and hence
\[ P_t (f \circ \text{Dil}_s) = (P_{st^2} f) \circ \text{Dil}_s . \]
Also, for any function \( f \), we have \( |df|_{\tilde{g}_{t^2}} \circ \text{Dil}_s = s^{-1} |df \circ \text{Dil}_s|_{g_t} \).

(v) Let \( Q \) be the homogeneous dimension of \( G \) as in (4.6). By definition \( \text{Dil}_s^* \mu = s^Q \mu \), and considering (iv) the heat kernel has the behavior
\[ g_{st^2} (\text{Dil}_s (x)) = s^{-Q} g_t (x) . \]

(vi) Clearly \( R^\nabla = 0 \) and \( \nabla T = 0 \) since the torsion takes left invariant vector fields to left invariant vector fields. Hence, for any left invariant vector field \( A \), we have \( A^\nabla A = \psi A \) with \( \psi \) as in (4.4). If \( \psi |h = 0 \), we can apply Theorem 4.1.

We obtain that for any \( v \in h \), then
\[ dP_t f (v) = \mathbb{E} \left[ \left( \frac{1}{t} \right) \frac{df}{g} (X_t) \{ v + \text{ad} (W_t) v \} \right] . \]

Theorem 4.3 now follows as a result of the next Lemma. Note that for any function \( f \in C^\infty (M) \), we have \( \nabla H f |_{\pi^{-1} m} = |df|_{\tilde{g}_t} \).

**Lemma 4.5.** Assume that \( \psi |h = 0 \). For every \( t > 0 \), define
\[ \vartheta_t = n + |\pi| |d \log g_t|_{\tilde{g}_t} . \]

For any \( p \in (1, \infty) \), let \( q \in [1, \infty) \) be such that \( \frac{1}{p} + \frac{1}{q} = 1 \) and define
\[ C_{t, p} = \mathbb{E} \left[ \vartheta_t (X_t)^q \right]^{1/q} . \]

Then
(a) \( C_{t, p} = C_{1, p} = C_p \) for any \( t > 0 \).
(b) The constants \( C_p \) are finite. Furthermore, we have the inequality

\[ C_2 \leq n + \left( nQ + 2 \int_G (n - |\pi|^2) d \log g \, d \mu \right)^{1/2} = n + \left( nQ - 2 \text{Cov}_{\pi} [ |\pi|^2, \log \rho ] \right)^{1/2} . \]

**Proof.** To simplify notation, we write \( \langle \cdot, \cdot \rangle_{L^2 (\pi, g^{\ast})} \) simply as \( \langle \cdot, \cdot \rangle \) and \( r = |\pi|^2 \).

(a) We use dilations to prove the statement. Observe that \( r \circ \text{Dil}_s = s^2 r \) and that \( |d \log g_t| \circ \text{Dil}_s = s^{-1} |d \log g_t/\sqrt{s}| \), and so \( \vartheta_t \circ \text{Dil}_s = \vartheta_{t/\sqrt{s}} \). It follows that
\[ \langle C_{1, p} \rangle^q = \int_G \vartheta_t \frac{d \mu}{\mu} \circ \text{Dil}_s^{\vartheta_t} \int_G \vartheta_t (\vartheta_{t/\sqrt{s}} - 1)^q \, d \mu \circ \text{Dil}_s^{\vartheta_t} \]
\[ = \int_G \vartheta_t \frac{d \mu}{\mu} = (C_p)^q . \]

(b) We only need to show that for any \( 1 < q < \infty \),
\[ \int_G g (r^{1/2} |d \log \rho|_{\tilde{g}_t})^q \, d \mu = \int_G r^{3/2} g^{1-q} |d \log \rho|_{\tilde{g}_t}^q \, d \mu < \infty . \]

Define \( d(x) = d_{\mu} (1, x) \). Then \( \pi \) is distance decreasing, so \( r (x) \leq d(x)^2 \). By [41, Theorem 1], for any \( 0 < \varepsilon < k_\varepsilon \) there is a constant \( k_\varepsilon \) such that
\[ \frac{1}{g(x)} \leq k_\varepsilon \exp \left( \frac{d^2 (x)}{2 - \varepsilon} \right) . \]
Furthermore, by [42, Theorem IV.4.2], for every $\varepsilon' > 0$ there are constants $k_{\varepsilon'}$ such that

$$|d\varrho|_{g_n}^2(x) \leq k_{\varepsilon'} \exp\left(-\frac{d^2(x)}{2 + \varepsilon'}\right).$$

Since we can always find the appropriate values of $\varepsilon$ and $\varepsilon'$ such that

$$\frac{q - 1}{q} \leq \frac{2 - \varepsilon}{2 + \varepsilon'},$$

it follows that $\int_G r^{q/2} q^{-q} |d\varrho|_{g_n}^2 \, d\mu < \infty$.

Next, define the vector field $D$ by $Df = \frac{d}{dt}(gf \circ \text{Dil}_{1+t})|_{t=0}$ for any function $f$. If $f$ satisfies $f \circ \text{Dil}_c = \varepsilon k f$, then by definition $Dg = kg$. By Item (v), we have

$$\text{div } D = Q, \quad (t\Delta_H + D + Q)p_t = (t\Delta_H - D^*)p_t = 0.$$  

The observation

$$\Delta_H (\varrho_t \log \varrho_t) = (\log \varrho_t + 1)\Delta_H \varrho_t + \varrho_t |\log \varrho_t|_{g_n}^2$$

allows us to compute

$$(C_2 - n)^2 \leq \langle r, \varrho \log \varrho \varrho \rangle \varrho^n = \langle r, \Delta_H (\varrho \log \varrho) - (\log \varrho + 1)\Delta_H \varrho \rangle$$

$$= \langle \Delta_H r, \varrho \log \varrho \rangle + \langle r, (\log \varrho + 1)D\varrho \rangle + \langle r, (\log \varrho + 1)\varrho \rangle$$

$$= 2n \langle \varrho, \varrho \varrho \rangle - \langle Dr, \varrho \varrho \rangle + Qn$$

$$= 2(n - r) \varrho \varrho + Qn$$

which equals the covariance, since $\int_M rpdf\mu = n$. \hfill \square

**Proof of Theorem 4.3.** Again, we write $\langle \cdot, \cdot \rangle_{L^2(M^{\infty}, g^*)}$ simply as $\langle \cdot, \cdot \rangle$ and $r = |\pi|^2$.

(a) By left invariance, it is sufficient to prove the inequality in the point $x = 1$. Let $v \in H_1 = \mathfrak{h}$ be arbitrary. We will use Theorem 4.1 and Item (vi). For every $x \in G$ we have $\text{Dr}(x) = 2x \cdot \pi(x)$. Let us consider the form $\alpha^v$ defined by $\alpha^v(x) = \langle x, v \rangle$. Then

$$dP_t f(v) = \mathbb{E} \left[ \langle I^{-1}f(X_t)(v - R(W_t, v)) \rangle \right]$$

$$= \mathbb{E} \left[ \langle I^{-1}f(X_t)(v) \rangle - \mathbb{E}[df(X_t) R(I^{-1}(\pi(X_t) \cdot v))] \right]$$

$$= \mathbb{E} \left[ \langle I^{-1}f(X_t)(v) \rangle - \frac{1}{2} \mathbb{E}[df R(\text{Dr}, \alpha^v)(X_t)] \right].$$

Define $F(A, B) = A \wedge \nabla_B$ and extend $F$ to general sections of $TM^{\otimes 2}$ by $C^\infty(M)$-linearity. Consider $F_H = F(g_n^*)$ and notice that

$$F_H f = dfH f = pr^*H df, \quad F_H^2 f = dfR(\cdot, \cdot).$$

Hence

$$\mathbb{E}[dfR(\text{Dr}, \alpha^v)(X_t)] = \langle F_H^2 f, \varrho \text{Dr} \wedge \alpha^v \rangle$$

$$= \langle F_H f, F_H (\varrho \text{Dr} \wedge \alpha^v) \rangle$$

$$= -\langle dfH f, r^*\alpha^v \rangle - \langle dH f, \varrho (\Delta_{g_n}^* r) \alpha^v \rangle + \langle dH f, \varrho \nabla_t \alpha^v \rangle$$

$$= -\langle dfH f, r^*\alpha^v \rangle - \langle dH f, \varrho (\Delta_{g_n}^* r) \alpha^v \rangle + \langle dH f, \varrho \nabla_t \alpha^v \rangle$$

$$= -\langle dfH f, r^*\alpha^v \rangle - \langle dH f, \varrho (\Delta_{g_n}^* r) \alpha^v \rangle + \langle dH f, \varrho \nabla_t \alpha^v \rangle.$$
Since $\nabla \alpha^v = 0$. We use the identities $\Delta_H r = 2n$ and $\nabla_A dr = 2\rho \text{pr}_H A$ to obtain
\[
\mathbb{E} \left[ \langle F_H^2 f, \delta r \wedge \alpha^v \rangle_{\gamma} (X_t) \right] = -\langle d_H f, \tau_{t} \log \rho \delta r \wedge \alpha^v \rangle - 2(n - 1)\langle d_H f, \rho \alpha^v \rangle
\]
\[
= -\mathbb{E} \left[ \langle d_H f, \tau_{t} \log \rho \delta r \wedge \alpha^v \rangle_{\gamma}(X_t) \right] - 2(n - 1)\mathbb{E} \left[ \langle /_t^{-1} d_H f(X_t)(v) \rangle \right].
\]
Hence, if we define $\mathcal{N}_t: T^*_1 G \to T^*_1 G$ by
\[
\mathcal{N}_t \beta = n \beta + \frac{1}{2} /_t^{-1} \tau_{t} \delta r(X_t)(d \log \rho(X_t) \wedge /_t \beta),
\]
then $dP_t f(v) = \mathbb{E} [\mathcal{N}_t /_t^{-1} df(v)]$ for any $v \in H$.

Observe that $|\mathcal{N}_t \beta|_{g_H} \leq \theta_t |\beta|_{g_H}$. Using Hölder’s inequality, this leads us to the conclusion
\[
|dP_t f|_{g_H}(1) = \sup_{v \in h, |v|_{g_H} = 1} dP_t f(v)
\]
\[
= \sup_{v \in h, |v|_{g_H} = 1} \mathbb{E} [\mathcal{N}_t /_t^{-1} df(X_t)(v)]
\]
\[
\leq \mathbb{E} [\varphi^0 \circ X_1]^{1/q} \mathbb{E} [\varphi^{p - 1} \circ X_1]^{1/p} \leq C_{t, p} (P_t [\varphi^{p - 1} \circ X_1])^{1/p}.
\]

(b) Using $dP_t v = \mathbb{E} [\mathcal{N}_t /_t^{-1}]$, for $p \in (2, \infty)$, $q \in [2, \infty)$ satisfying
\[
\frac{1}{q} + \frac{1}{p} + \frac{1}{2} = 1,
\]
we have
\[
|dP_t f|_{g_H}(1) \leq n \mathbb{E} [\varphi |\alpha|_{g_H}(X_1)] + \mathbb{E} [\langle /_t \varphi |\log \rho|_{g_H} |df|_{g_H} \rangle (X_1)]
\]
\[
\leq n P_t [\varphi]_{g_H} + \mathbb{E} [\varphi |\alpha|_{g_H} (X_1)]^{1/q} \mathbb{E} \left[ \log \varphi |\alpha|_{g_H} (X_1) \right]^{1/2} \mathbb{E} [\varphi^{p - 1} \circ X_1]^{1/p}.
\]

As was observed in [8, page 9],
\[
\mathbb{E} \left[ |\log \varphi |^2 \circ X_1 \right] = \int_M \rho |\log \rho|_{g_H}^2 d\mu = \int_M (\Delta_H (\rho \log \rho) - (\log \rho + 1) \Delta_H \rho) d\mu
\]
\[
= \int_M (\log \rho + 1)(D + Q) \rho d\mu = \int_M D(\rho \log \rho) d\mu + Q \int_M (\log \rho + 1) \rho d\mu
\]
\[
= \int_M (D + Q) \rho d\mu = Q
\]
while
\[
\mathbb{E} [\varphi |\alpha|_{g_H} (X_1)] = \mathbb{E} [\varphi |W_1|] = \frac{2^{(q + n + 1)/2} \pi^{(n - 1)/2} \Gamma(\frac{n + q}{2})}{\pi^{n/2} \Gamma(\frac{n}{2})}
\]

The result follows.

Remark 4.6. Consider a Carnot group $(G, H, g_H)$ and let $V$ be the complement of $V$ defined by left translation of $g_2 \oplus \cdots \oplus g_k$. Since this is an ideal, we obtain the same subbundle using right translation. Extend the $g_H$ to a Riemannian metric $g$ by defining a right invariant metric on $V$. Then condition (3.5) holds, but if $\nabla$ is defined as in (3.7), then $\text{Ric}(\nabla)$ does not have a lower bound for $k \geq 3$. However, the Yang-Mills condition $\text{tr}_H(\nabla_x R)(\cdot, \cdot) = 0$ of Remark 3.15 equals exactly the condition $\psi |h| = 0$. 

Appendix A. Feynman-Kac formula for perturbations of self-adjoint operators

A.1. Essentially self-adjoint operator on forms. Let $M$ be a manifold with a sub-Riemannian structure $(H, g_H)$ with $H$ bracket-generating. Consider the rough sub-Laplacian $L = L(\nabla)$ relative to some affine connection $\nabla$ on $TM$. Let $g$ be a complete sub-Riemannian metric taming $g_H$ such that $\nabla g = 0$. Assume that

$$L^* = L = - (\nabla_{pr_H})^*(\nabla_{pr_H}).$$

We can then make the following statement for operators of the type $L = \mathcal{C}$ where $\mathcal{C} \in \Gamma(\text{End}(T^* M))$. To simplify notation, we denote $\langle \cdot, \cdot \rangle_{L^2(\lambda g^*)}$ as simply $\langle \cdot, \cdot \rangle$ for the rest of this section.

Lemma A.1. Assume that $\mathcal{C}^* = \mathcal{C}$. If $\mathcal{A} = L - \mathcal{C}$ is bounded from above on compactly supported forms, i.e. if

$$\lambda_0 = \lambda_0(\mathcal{A}) = \sup \left\{ \frac{\langle A\alpha, \alpha \rangle}{\langle \alpha, \alpha \rangle} : \alpha \in \Gamma_c(T^* M) \right\} < \infty,$$

then $\mathcal{A}$ is essentially self-adjoint on compactly supported one-forms.

We follow the argument of [37, Section 2]. We begin by introducing the following lemma.

Lemma A.2. [34, Section X.1] Let $\mathcal{A}$ be any closed, symmetric, densely defined operator on a Hilbert space with domain $\text{Dom}(\mathcal{A})$. Assume that $\mathcal{A}$ is bounded from above by $\lambda_0(\mathcal{A})$ on its domain. Then $\mathcal{A} = \mathcal{A}^*$ if and only if there are no eigenvectors in the domain of $\mathcal{A}^*$ with eigenvalue $\lambda > \lambda_0(\mathcal{A})$.

Proof of Lemma A.1. Let $pr_H$ be the orthogonal projection to $H$. Since $L = - (\nabla_{pr_H})^*(\nabla_{pr_H})$, we have $- \langle \mathcal{C} \alpha, \alpha \rangle \leq \lambda_0(\alpha, \alpha)$. Denote the closure of $\mathcal{A} \Gamma_c(T^* M)$ by $\mathcal{A}$ as well. Assume that there exist a one-form $\alpha$ in $L^2$ satisfying $\mathcal{A}^* \alpha = \lambda \alpha$ with $\lambda > \lambda_0$. By using a trivialization of the cotangent bundle, we see that $L$ is hypoelliptic, which implies that $\alpha$ is smooth. Let $f$ be an arbitrary function of compact support and write $d_H f = pr_H^* df$. Then

$$\lambda \langle f^2 \alpha, \alpha \rangle = \langle f^2 \alpha, \mathcal{A}^* \alpha \rangle = \langle \mathcal{A}(f^2 \alpha), \alpha \rangle$$

$$= - \langle f^2 \nabla_{pr_H} \alpha, \nabla_{pr_H} \alpha \rangle - \langle f^2 \mathcal{C} \alpha, \alpha \rangle - 2 \langle f d_H f \otimes \alpha, \nabla_{pr_H} \alpha \rangle$$

$$\leq - \|f \nabla_{pr_H} \alpha\|^2_{L^2(g^*)} + \lambda_0 f^2 \langle \alpha, \alpha \rangle - 2 \langle d_H f \otimes \alpha, f \nabla_{pr_H} \alpha \rangle.$$

Since $(\lambda - \lambda_0) (f^2 \alpha, \alpha) \geq 0$, we have

$$\|f \nabla_{pr_H} \alpha\|^2_{L^2(g^*)} \leq - 2 \langle d_H f \otimes \alpha, f \nabla_{pr_H} \alpha \rangle,$$

and hence

$$\langle f \nabla_{pr_H} \alpha, \alpha \rangle_{L^2(g^*)} \leq 2 \|d_H f\|_{L^\infty(g^*)} \|\alpha\|_{L^2(g^*)} \|f \nabla_{pr_H} \alpha\|_{L^2(g^*)}.$$

Since we assumed that $g$ was complete, there exist a sequence of smooth functions $f_j \uparrow 1$ of compact support satisfying $\|f_j\|_{L^\infty(g^*)} \rightarrow 0$. By inserting $f_j$ in (A.1) and taking the limit we obtain $\|\nabla_{pr_H} \alpha\|^2_{L^2(g^*)} = - \langle \lambda \alpha, \alpha \rangle = 0$. However, this contradicts our initial hypothesis $\mathcal{A}^* \alpha = \lambda \alpha$ for $\lambda > \lambda_0$. Hence, we obtain our result. \[\square\]
Remark A.3. By replacing the sequence $f_j$ in the proof of Lemma A.1 with (an appropriately smooth approximation of) the sequence found in [38, Theorem 7.3], we can deduce essential self-adjointness of $L - \mathcal{C}$ just by assuming completeness of $d g_H$.

A.2. Stochastic representation of a semigroup. Let $(M, H, g_H)$ be a sub-Riemannian manifold and let $g$ be a complete Riemannian metric taming $g_H$. Define $L^2(T^* M)$ as the space of all one-forms in $L^2$ relative to $g$. Let $\nabla$ be a connection satisfying $\nabla g = 0$ and $L^* = L$. Relative to $L(\nabla)$, consider the stochastic flow $X_t(\cdot)$ with explosion time $\tau(\cdot)$. Define $//_t(x)$ as parallel transport along $X_t(x)$ with respect to $\nabla$.

Let $\mathcal{C}$ be a zero order operator on $M$, with
\[ \mathcal{C}^s = \frac{1}{2}(\mathcal{C} + \mathcal{C}^*), \quad \mathcal{C}^a = \frac{1}{2}(\mathcal{C} - \mathcal{C}^*). \]

Lemma A.4. Assume that $L - \mathcal{C}^s$ is bounded from above and assume that $\mathcal{C}^a$ is bounded. For each $x$, let $Q_t(x) \in \text{End} T^*_x M$ a continuous process adapted to the filtration of $X_t(x)$ such that for any $\alpha \in \Gamma_c(T^*_x M)$, we have
\[ d\left(Q_t(x)/t^{-1}\alpha(X_t(x))\right)_{\text{loc,m.}} = Q_t(x)/t^{-1}(L - \mathcal{C})\alpha(X_t(x))\,dt, \]
where $\text{loc,m.}$ denotes equality modulo differentials of local martingales.

Then there exists a strongly continuous semigroup $P_t^{(1)}$ on $L^2(T^* M)$ such that for any $\alpha \in L^2(T^* M)$,
\[ P_t^{(1)}\alpha(x) = \mathbb{E}\left[\sum_{t<\tau(x)} Q_t(x)/t^{-1}\alpha(X_t(x))\right], \]
and such that $\lim_{t \downarrow 0} \frac{d}{dt} P_t^{(1)} \alpha = (L - \mathcal{C})\alpha$ for any $\alpha \in \Gamma_c(T^* M)$.

For the proof, we need to consider a special class of Volterra operators. To this end, we follow the arguments of [20, Section III.1]. Let $\mathcal{B}$ be a Banach space and let $\mathcal{L}(\mathcal{B})$ be the space of all bounded operators on $\mathcal{B}$ with the strong operator topology. Consider any strongly continuous semigroup $\mathbb{R}_{\geq 0} \to \mathcal{L}(\mathcal{B})$, $t \mapsto S_t$ and let $\mathcal{A} : \mathcal{B} \to \mathcal{B}$ be a bounded operator. We define the corresponding Volterra operator $V(S; \mathcal{A})$ on continuous functions $\mathbb{R}_{\geq 0} \to \mathcal{L}(\mathcal{B})$, $(t, \alpha) \mapsto F_t \alpha$ by
\[ (V(S; \mathcal{A}) F)_t \alpha = \int_0^t S_{t-r} \mathcal{A} F_r \alpha \,dr, \]
and introduce the operator $T(S; \mathcal{A})$ by
\[ T(S; \mathcal{A}) F = \sum_{n=0}^\infty V(S; \mathcal{A})^n F. \]

The operator $T(S; \mathcal{A})$ is well defined, and if $S_t$ has generator $(L, \text{Dom}(L))$ then $\hat{S}_t := (T(S; \mathcal{A}) S)_t$ defines a strongly continuous semigroup with generator $(L + \mathcal{A}, \text{Dom}(L))$.

Proof. By Lemma A.1 the operator $L - \mathcal{C}^s$ is essentially self-adjoint. Let $P_t^s$ be the corresponding semigroup on $L^2(T^* M)$ with domain $\text{Dom}^s = \text{Dom}(L - \mathcal{C}^s)$.

Let $D^n$ be an exhausting sequence of $M$ of relative compact domains, see e.g. [16, Appendix B.1] for construction. Consider the Friedrichs extension $(\mathcal{A}^n, \text{Dom}(\mathcal{A}^n))$ of $L - \mathcal{C}^s$ restricted to compactly supported forms on $D^n$ and let $\tilde{P}_t^n$ be the corresponding semigroup defined by a spectral theorem. Since the operators $\mathcal{A}^n$ are...
bounded from above by assumption, the semigroups $\hat{P}^n$ are strongly continuous by [20, Chapter II.3.c]. Define $P^t$ similarly with respect to the unique self-adjoint extension of $L - \mathcal{E}^0$ restricted to compactly supported forms. Let $(\Lambda, \text{Dom}(\Lambda))$ denote the generator of $P^t$ and note that for any compactly supported forms $\alpha$, we have that $\hat{P}^n\alpha$ converge to $P^t\alpha$ in $L^2(TM)$, by e.g. [29, Chapter VIII.3.3]. Define $P^n_t = (\mathcal{T}(\hat{P}^n; \mathcal{E})\hat{P}^n)_t$ and finally $P^{(1)}_t = (\mathcal{T}(P^n; \mathcal{E}^0)P^n)_t$. These semigroups are strongly continuous with respective generators $(\Lambda^n + \mathcal{E}^0, \text{Dom}(\Lambda^n))$ and $(\Lambda + \mathcal{E}^0, \text{Dom}(\Lambda))$. Furthermore, $P^n_t\alpha$ converge to $P^{(1)}_t\alpha$ in $L^2(TM)$ by [29, Theorem IV.2.23 (c)].

For $x \in M$, let $\tau_n(x)$ denote the first exit time for $X_t(x)$ of the domain $D^n$. For any form $\alpha$ with support in $D^n$, we have that for $S > 0$ and $n \geq k$,

$$N^n_t = Q_t(x)/\int [P^n_{S-t}\alpha]|_{X_t(x)}$$

is a bounded local martingale, giving us

$$P^n_t\alpha(x) = E\left[1_{t<\tau_n(x)}Q_t(x)/\int [P^n_{S-t}\alpha]|_{X_t(x)}\right].$$

Taking the limit, and using that $P^n_t$ converges to $P^{(1)}_t$, we obtain

$$P^{(1)}_t\alpha(x) = E\left[1_{t<\tau(x)}Q_t(x)/\int [P^{(1)}_{S-t}\alpha]|_{X_t(x)}\right].$$
