SCATTERING THEORY BELOW ENERGY SPACE FOR TWO DIMENSIONAL NONLINEAR SCHRÖDINGER EQUATION

CHANGXING MIAO AND JIQIANG ZHENG

Abstract. The purpose of this paper is to illustrate the I-method by studying low-regularity solutions of the nonlinear Schrödinger equation in two space dimensions. By applying this method, together with the interaction Morawetz estimate [8, 36], we establish global well-posedness and scattering for low-regularity solutions of the equation

\[ iu_t + \Delta u = \lambda_1 |u|^p u + \lambda_2 |u|^{p/2} u \]

under certain assumptions on parameters. This is the first result of this type for an equation which is not scale-invariant. In the first step, we establish global well-posedness and scattering for low regularity solutions of the equation

\[ iu_t + \Delta u = |u|^p u, \quad (t, x) \in \mathbb{R} \times \mathbb{R}^2, \]

for a suitable range of the exponent \( p \) extending the result of Colliander, Grillakis and Tzirakis [Comm. Pure Appl. Math. 62(2009), 920-968.]

Key Words: nonlinear Schrödinger equation; global well-posedness; scattering; low regularity.

AMS Classification: 35Q55.

1. Introduction

We consider the initial-value problem for the defocusing nonlinear Schrödinger equation

\[ \begin{cases} (i\partial_t + \Delta) u = f(u), & (t, x) \in \mathbb{R} \times \mathbb{R}^2, \\ u(0, x) = u_0(x), \end{cases} \]

(1.1)

where \( u : \mathbb{R} \times \mathbb{R}^2 \to \mathbb{C} \). If \( f(u) = |u|^p u \), the equation in (1.1) is invariant under the scaling transform

\[ u(t, x) \mapsto \lambda^{2/p} u(\lambda^2 t, \lambda x), \quad \text{for any } \lambda > 0, \]

(1.2)

and this scaling property leads to the notion of criticality for problem (1.1). Indeed, one can verify that the homogeneous Sobolev space \( H^{s_c}(\mathbb{R}^2) \) with the critical regularity index \( s_c := 1 - \frac{2}{p} \) is invariant under scaling (1.2). Then, for every \( u_0 \in H^{s_c}(\mathbb{R}^2) \), we refer to the problem (1.1) as critical if \( s = s_c \), subcritical for \( s > s_c \), and supercritical if \( s < s_c \).

If a smooth solution \( u \) of problem (1.1) has sufficient decay at infinity, it conserves mass

\[ M(u) = \int_{\mathbb{R}^2} |u(t,x)|^2 \, dx = M(u_0) \]

(1.3)

and the energy

\[ E(u(t)) = \int_{\mathbb{R}^2} \left( \frac{1}{2} |\nabla u(t)|^2 + F(u) \right) \, dx = E(u_0), \quad F(u) = \int_0^{[u]} f(s) \, ds. \]

(1.4)

The global well-posedness and scattering theory for the defocusing Schrödinger equation (NLS)

\[ \begin{cases} (i\partial_t + \Delta) u = |u|^p u, & (t, x) \in \mathbb{R} \times \mathbb{R}^d, \\ u(0, x) = u_0(x) \in H^s(\mathbb{R}^d), \end{cases} \]

(1.5)
has been intensively studied in papers [14, 15, 11, 13, 14, 25–31]. Recall that a global solution \( u \) to (1.5) scatters in \( H^s(\mathbb{R}^d) \), if there exist unique state \( u_\pm \in H^s_\pm(\mathbb{R}^d) \) such that
\[
\lim_{t \to \pm \infty} \| u(t) - e^{it\Delta} u_\pm \|_{H^s_\pm(\mathbb{R}^d)} = 0.
\]
In the energy-subcritical case, i.e. for \( p \in \left( \frac{4}{d}, \frac{d}{d-2} \right) \) if \( d \geq 3 \) and for \( p \in \left( \frac{4}{d}, +\infty \right) \) if \( d \in \{1, 2\} \), for every \( u_0 \in H^1(\mathbb{R}^d) \), it is easy to prove the global well-posedness for problem (1.5) by combining the Strichartz estimate together with a standard fixed point argument and the conservation of energy. Ginibre and Velo [25] proved the scattering in spatial dimension \( d \geq 3 \) by making use of the almost finite propagation speed
\[
\int_{|x| \geq a} |u(t,x)|^2 \, dx \leq \int \min \left( \frac{|x|}{a}, 1 \right) |u(t_0)|^2 \, dx + C \cdot |t - t_0|
\]
for large spatial scale and the classical Morawetz inequality in [32]
\[
\iint_{\mathbb{R} \times \mathbb{R}^d} \frac{|u(t,x)|^{p+2}}{|x|} \, dt \, dx \lesssim \| u \|^2_{L^\infty_t H^\frac{d}{p+2}} \lesssim C(M(u_0), E(u_0)) \tag{1.6}
\]
for small spatial scale. It is well known that the Morawetz estimate is an essential tool in the proof of scattering for the nonlinear dispersive equations such as nonlinear Schrödinger equations and nonlinear Klein-Gordon equations. A classical Morawetz inequality was first derived by Morawetz [33] for the nonlinear Klein-Gordon equation, and then extended by Lin and Strauss [34] to the nonlinear Schrödinger equation with \( d \geq 3 \) in order to obtain the scattering for slightly more regular solutions. Next, Nakanishi [35] extended the above Morawetz inequality to the dimensions \( d \in \{1, 2\} \) by considering certain variants of the Morawetz estimate with space-time weights and consequently he proved the scattering in low dimensions.

The Morawetz estimate (1.6) plays an important role in the proof of scattering for the problem (1.5) in the energy-subcritical case, but it does not work so powerfully in the energy-critical case (i.e. for \( p = \frac{d}{d-2} \) if \( d \geq 3 \)). Thus, to obtain the scattering in the critical case, it is a very difficult problem. An essential breakthrough came from Bourgain [3] who exploited the ‘induction on energy’ technique and the following spatial-localized Morawetz inequality
\[
\int I \int_{|x| \leq C|I|^\frac{d}{2}} \frac{|u(t,x)|^6}{|x|} \, dt \, dx \lesssim |I|^\frac{1}{2} C \left( \| u \|^2_{L^\infty_t H^1(I \times \mathbb{R}^3)} \right) \tag{1.7}
\]
to obtain the scattering of radial solutions to problem (1.5) with \( p = 4 \) in the energy space \( H^1(\mathbb{R}^3) \). Next, Colliander, Keel, Staffilani, Takaoka and Tao (I-team [17]) removed the radial symmetry assumption in [3], and solved this longtime standing problem through the Bourgain ‘induction on energy’ technique and the frequency localized type of the interaction Morawetz inequality
\[
\| \nabla \|^{\frac{4}{d-2}}_L^2 (|u|^2)^2 \|_{L^2_t(\mathbb{R} \times \mathbb{R}^d)} \lesssim \| u_0 \|^2_{L^2} \| u \|^2_{L^\infty_t(\mathbb{R} \times H^\frac{d}{2})}, \quad d \geq 1. \tag{1.8}
\]
This interaction Morawetz inequality was first derived by I-team in their work [17] in spatial dimension \( d = 3 \) and then extended to \( d \geq 4 \) in [39]. Colliander, Grillakis and Tzirakis [9], Planchon and Vega [30] independently proved (1.8) in dimensions \( d \in \{1, 2\} \). As a byproduct, one can easily give another simpler proof of the result of Ginibre and Velo [25], see [39] for more detail. We also refer the reader to [24] for the exposition on the Morawetz inequalities and their applications.

The interaction Morawetz inequality plays also an important role in the study of a low regularity problem. Where we ask what is the minimal \( s \) to ensure that problem (1.5) has either a local solution or a global solution for which the scattering hold? Such a problem was first considered by Cazenave and Weissler [3], who proved that problem (1.5) is locally well posed in \( H^s(\mathbb{R}^d) \) with \( s \geq \max \{0, s_c \} \) and globally well posed together with scattering for small
data in $\dot{H}^{s_c}(\mathbb{R}^d)$ with $s_c \geq 0$. They used Strichartz estimates in the framework of Besov spaces. On the other hand, since the lifespan of local solutions depend only on the $H^s$-norm of the initial data for $s > \max\{0, s_c\}$, one can easily obtain the global well-posedness for \eqref{1.5} in two special cases: the mass subcritical case $(p < \frac{4}{d})$ for $L^2_x(\mathbb{R}^d)$-initial data and the energy-subcritical case (for $p < \frac{4}{d-2}$ if $d \geq 3$ or for $p < +\infty$ if $d \in \{1, 2\}$) for $H^1_x(\mathbb{R}^d)$-initial data by using the conservation of mass and energy respectively.

This leaves the open problem on global well-posedness in $H^s(\mathbb{R}^d)$ in the intermediate regime $0 \leq s_c \leq s < 1$. The first progress on this direction came from the Bourgain ‘Fourier truncation method’ \cite{1} where refinements of Strichartz’ inequality \cite{2}, high-low frequency decompositions and perturbation methods were used to show that problem \eqref{1.5} with $p = 2$ is globally wellposed in $H^s(\mathbb{R}^3)$ with $s > \frac{11}{14}$ such that

$$u(t) - e^{it\Delta}u_0 \in H^1(\mathbb{R}^3).$$

This leads to the I-method which was derived by Keel and Tao in the study of wave maps \cite{29}. Subsequently, I-team developed the I-method to treat many low regularity problems including the nonlinear Schrödinger equations with derivatives, the one dimensional quintic NLS, and the cubic NLS in two and three dimensions \cite{10,15}. Compared with the result in \cite{1}, I-team also obtained the scattering in $H^s(\mathbb{R}^3)$ with $s > \frac{5}{7}$ by using the I-method and the interaction Morawetz estimate \cite{18} in \cite{16}. Dodson \cite{20} extended those results to $s > \frac{7}{8}$ by means of a linear-nonlinear decomposition, and then Su \cite{38} to $s > \frac{5}{7}$. For the cubic NLS in dimension two (corresponding to the mass-critical), I-term further exploited the improved I-method in \cite{15} to get the global well-posedness for $s > \frac{1}{5}$. Colliander, Grillakis and Tzirakis \cite{7} extended it to $s > \frac{7}{8}$ by means of the I-method and the improved interaction Morawetz inequalities. Laterly, Colliander and Roy \cite{13} improved these results to $s > \frac{1}{5}$. Subsequently, Dodson \cite{19} showed the global well-posedness for $s > \frac{1}{5}$ by improving the almost Morawetz estimates from \cite{7}.

The study of a low regularity problem stimulates the development of the scattering in $L^2(\mathbb{R}^d)$ for the mass-critical problem (i.e. for $p = \frac{4}{d}$). Dodson \cite{22,23} developed so called long-time Strichartz estimates to prove the global well-posedness and scattering in $L^2_x$-space by making use of a concentration-compactness approach and the idea of I-method.

Now, let us describe the I-method, which consists in smoothing out the $H^s$-initial data with $0 < s < 1$ in order to access a good local and global theory available at the $H^1$-regularity. To do it, we define the Fourier multiplier $I$ by

$$\widehat{Iu}(\xi) := m(\xi)\hat{u}(\xi),$$

where $m(\xi)$ is a smooth radial decreasing cut off function such that

$$m(\xi) = \begin{cases} 1, & |\xi| \leq N, \\ \left(\frac{|\xi|}{N}\right)^{s-1}, & |\xi| \geq 2N. \end{cases} \quad (1.10)$$

Thus, $I$ is the identity operator on frequencies $|\xi| \leq N$ and behaves like a fractional integral operator of order $1-s$ on higher frequencies. It is easy to show that the operator $I$ maps $H^s$ to $H^1$. Moreover, we have

$$\|u\|_{H^s} \lesssim \|Iu\|_{H^s} \lesssim N^{1-s}\|u\|_{H^s}. \quad (1.11)$$

Thus, to prove that problem \eqref{1.6} is globally well-posed in $H^s(\mathbb{R}^d)$, it suffices to show that $E(Iu(t)) < +\infty$ for all $t \in \mathbb{R}$. Since $Iu$ is not a solution to \eqref{1.6}, the modified energy $E(Iu)(t)$ is not conserved. Indeed, we have

$$\frac{d}{dt}E(Iu(t)) = \operatorname{Re} \int_{\mathbb{R}^d} \overline{u(t)} \left[|Iu|^pIu - I(|u|^pu)\right] dx. \quad (1.12)$$
Thus, the key idea is to show that the modified energy $E(Iu)$ is an ‘almost conserved’ quantity in the sense that its derivative $\frac{d}{dt}E(Iu(t))$ will decay with respect to a large parameter $N$. This will allow us to control $E(Iu)$ on time interval where the local solution exists and we can iterate this estimate to obtain a global in time control of the solution by means of the bootstrap argument, see Section 3 for more details. Then immediately we get a bound for the $H^1$-norm of $Iu$ which will give us an $H^s$-bound for the solution $u$ by inequality (1.11).

To deal with equality (1.12), one needs complicated estimates on the commutator $I(|u|^pu) − |Iu|^pIu$. When $p$ is an even integer, one can write the commutator explicitly by means of the Fourier transform and to control it by multilinear harmonic analysis, see [7, 9, 15, 18, 21, 38, 40] for considerations of the algebraic nonlinearity $f(u) = |u|^{2k}u$ with $k \in \mathbb{N}$ in $\mathbb{R}^d (d = 1, 2)$ and cubic NLS in $\mathbb{R}^3$. Colliander, Grillakis and Tzirakis [8] proved that a solution to (1.5) with $f(u) = |u|^{2k}u$ is global and scatters for $s > 1 - \frac{1}{2k}$ in $\mathbb{R}^2$. Recently, by exploiting the long-time Strichartz estimate in the Koch-Tataru space $U^2_\Delta$ and $V^2_\Delta$ (see [30, 31]), Dodson [21] extended this result to $s > 1 - \frac{1}{k}$ for radial initial data.

Unfortunately, the above method for estimating (1.12) depends heavily on the exact form of the nonlinearity. Therefore, this method fails when $p$ is not an even integer. For arbitrary $p \in (0, 4/(d − 2))$ and $d \geq 3$, by relying on more rudimentary tools as Taylor’s expansion and Strichartz estimates, I-team [14] obtained polynomial growth of the $H^s$-norm of solutions, and so the global well-posedness for problem (1.5) with $s$ sufficiently close to 1. However, their bounds are insufficient to yield scattering. Subsequently, Visan and Zhang [41] combined the I-method and the a priori interaction Morawetz estimate (1.8) to show that scattering holds in $H^s(\mathbb{R}^d)$ for $s$ being larger than some $s_0(d, p) \in (0, 1)$. This method is weaker than the multilinear multiplier method when $p$ is an even integer.

I-method also relies on the scale-invariance of the equation in (1.5). Therefore, adding a perturbation to the equation which destroys the scale invariance, is of particular interest. By this reason, we study the nonlinear Schrödinger equation (1.5) which is perturbed by a lower-order nonlinearity

$$\begin{cases}
(i\partial_t + \Delta)u = |u|^{p_1}u + |u|^{p_2}u, & (t, x) \in \mathbb{R} \times \mathbb{R}^2, \quad p_1 < p_2, \\
u(0, x) = u_0(x).
\end{cases}$$

(1.13)

We look for answers to the following questions: under which conditions on $p_1$ and $p_2$ a solution to problem (1.13) is unique global in time in $H^s(\mathbb{R}^2)$ with suitable $s$, and is scattering? We use a certain perturbative and scale technique. We first remove the term $|u|^{p_2}u$ and study the global well-posedness and scattering for (1.1) with general nonlinearity $f(u) = |u|^pu$ by arguments of [11] combined with the a priori interaction Morawetz estimates in [8, 36]. Then, we apply the I-method to an equation derived from that in (1.13) by the scaling transform (1.2).

Now, we collect our results into the following theorems. We define

$$s_0 := \max \left\{ \frac{-2s_c}{p_1 - s_1} - 1, \quad s_1 \right\}, \quad s_1 = 1 - \frac{4}{p_1}.$$

(1.14)

and $s_1$ is the positive root of the quadratic equation

$$s^2 + 2s_c s + s_c^2 = 4s_c = 0.$$

Theorem 1.1. Assume that $u_0 \in H^s(\mathbb{R}^2)$ with $s \in (s_0, 1)$, $p > \frac{11}{8}$. Then the solution $u$ to (1.1) with $f(u) = |u|^pu$ is global and scatters in the sense that there exist unique $u_{\pm} \in H^s_+(\mathbb{R}^2)$ such that

$$\lim_{t \to \pm \infty} \|u(t) - e^{it\Delta}u_{\pm}\|_{H^s_+(\mathbb{R}^2)} = 0.$$

(1.15)

Remark 1.1. There exists a gap for the region $2 < p < \frac{11}{8}$. The restriction to $p \geq \frac{11}{8}$ comes from estimate (3.9) in Proposition 3.1 and estimate (5.24) in Proposition 5.2 since the classical
interaction Morawetz estimates are not good enough to control this time-space norm. We refer to Propositions 3.1 and 3.3 for more detail.

Now, we want to deal with the case \( f(u) = |u|^p u \) with \( p < \frac{4}{3} \). We will apply the following improved interaction Morawetz estimates in [7]

\[
\int_0^T \int_{\mathbb{R}^2} |u(t, x)|^4 \, dx \, dt \lesssim T^{\frac{4}{3}} \| u_0 \|_{L^2_x}^2 \| u \|_{L^\infty([0, T], H^{1/2})}^2 + T^{\frac{4}{3}} \| u_0 \|_{L^2_x}^4 \tag{1.16}
\]

instead of the following classical interaction Morawetz estimates in [8, 36]

\[
\| u \|_{L^4_x(I \times \mathbb{R}^2)} \lesssim \| u \|_{L^\infty(I, H^{1/2}(\mathbb{R}^2))}^2 \| u_0 \|_{L^2_x}^2 . \tag{1.17}
\]

The estimate (1.16) will help us to obtain global well-posedness with the lower order \( H^s \)-norm of the solution depends on the polynomial growth of time, which is insufficient to yield scattering. Let us define

\[
\tilde{s}_0 := \max \left\{ \frac{3}{2} + \frac{4}{p+1}, \tilde{s}_1 \right\}, \quad \tilde{s}_c = 1 - \frac{2}{p},
\]

and \( \tilde{s}_1 \) be the positive root of the quadratic equation

\[
3(s - s_c)^2 - 2(1 + 6s_c)(1 - s) = 0.
\]

**Theorem 1.2.** Assume that \( u_0 \in H^s(\mathbb{R}^2) \) with \( s \in (s_0, 1) \) and \( p > 2 \). Then the solution \( u \) to (1.1) with \( f(u) = |u|^p u \) is global. Furthermore, we have the polynomial growth of the \( H^s \)-norm of the solution,

\[
\sup_{t \in [0, T]} \| u(t) \|_{H^s(\mathbb{R}^2)} \leq C \left( \| u_0 \|_{H^s(\mathbb{R}^2)} \right)(1 + T)^{\frac{s-1}{2(p-1)(s-\frac{1}{2})}}, \quad \forall \ T > 0. \tag{1.19}
\]

Now we turn to problem (1.13) with \( p_2 = 2k, \ k \in \mathbb{N} \) and \( p_1 = p \). Denote

\[
s_c^{(1)} = 1 - \frac{2}{p}, \quad s_c^{(2)} = 1 - \frac{1}{p},
\]

and

\[
\tilde{s}_3 := \max \left\{ \frac{1+s_c^{(1)}}{2}, \frac{2k}{2k+1}, \frac{s_c^{(2)}}{4s_c^{(2)}+1}, \ s_3 \right\}
\]

where \( s_3 \) is the positive root of the quadratic equation

\[
s^2 - (s_c^{(1)} + s_c^{(2)} - \alpha)s - \alpha = 0, \quad \alpha = 4s_c^{(2)} + \frac{9(p-\frac{4}{3})}{2(p+2)}.
\]

**Theorem 1.3.** Assume that \( u_0 \in H^s(\mathbb{R}^2) \) with

\[
s \in (s_3, 1), \quad 2k > p \geq \frac{11}{4} \quad \text{and} \quad 1 < k \in \mathbb{N}.
\]

Then the solution \( u \) to (1.1) with \( f(u) = |u|^{2k} u + |u|^p u \) is global and scatters in \( H^s(\mathbb{R}^2) \).

**Remark 1.2.** A simple computation shows \( \tilde{s}_3 > s_0 \) here. Our argument also works in the higher dimensional case. By the same way as in the proof of Theorem 1.2, one can also use the improved interaction Morawetz estimates (1.16) to achieve the global well-posedness of (1.13) with \( p \in [2, \frac{11}{4}) \).

Finally, we give the global well-posedness and scattering result for (1.1) with more general nonlinearity \( f(u) = |u|^p u + |u|^{p_2} u \) by the same arguments as those in the proofs of Theorems 1.1 and 1.3.
Theorem 1.4. Assume that \( u_0 \in H^s(\mathbb{R}^2) \) with
\[
s \in \left( \max \left\{ \frac{1+s_{(2)}}{2}, \frac{p_2}{p_2+1}, s_2 \right\}, 1 \right), \quad s^{(j)}_c = 1 - \frac{j}{p_j}, \quad j = 1, 2, \quad \frac{11}{4} \leq p_1 < p_2
\]
and \( s_2 \) is the positive root of the quadratic equation
\[
s^2 + 2s_{(2)}^2 s + (s_{(2)}^2 - 4s_c^{(2)}) = 0.
\]
Then the solution of problem (1.1) with \( f(u) = |u|^{p_1} u + |u|^{p_2} u \) is global and scatters in \( H^s(\mathbb{R}^2) \).

The paper is organized as follows. In Section 2, as preliminaries, we gather some notations and recall the Strichartz estimate for NLS and some nonlinear estimates. In Section 3, we will utilize I-method and the improved interaction Morawetz inequalities to show Theorem 1.2. We prove Theorem 1.3 in Section 4 based on Theorem 1.1. In Appendix, we state a result in one dimension.

2. Preliminaries

2.1. Notations. To simplify our inequalities, we introduce the symbols \( \lesssim, \sim, \ll \). If \( X, Y \) are nonnegative quantities, we write either \( X \lesssim Y \) or \( X = \mathcal{O}(Y) \) to denote the estimate \( X \leq CY \) for some \( C \), and \( X \sim Y \) to denote the estimate \( X \lesssim Y \lesssim X \). We use \( X \ll Y \) to mean \( X \leq cy \) for some small constant \( c \). We use \( C \gg 1 \) to denote various large finite constants, and \( 0 < c \ll 1 \) to denote various small constants. For every \( r \) such that \( 1 \leq r < \infty \), we denote by \( \| \cdot \|_r \) the norm in the Lebesgue space \( L^r(\mathbb{R}^d) \) and by \( r' \) the conjugate exponent defined by \( \frac{1}{r} + \frac{1}{r'} = 1 \). We denote by \( a \pm \epsilon \) quantities of the form \( a \pm \epsilon \) for any \( \epsilon > 0 \). We always assume \( d = 2 \) and \( s < 1 \).

Let \( f(z) := |z|^{p_1} z \), then
\[
f_z(z) := \frac{\partial f}{\partial z}(z) = \frac{p_1 + 2}{2} |z|^{p_1} \quad \text{and} \quad f_z(z) := \frac{\partial f}{\partial z}(z) = \frac{p_1 + 1}{2} |z|^{p_1}.
\]
We denote \( F' \) to be the vector \( (f_z, f_{\bar{z}}) \) and use the notation
\[
w \cdot f'(z) = w f_z(z) + \bar{w} f_{\bar{z}}(z).
\]
In particular, we get by the chain rule
\[
\nabla f(u) = \nabla u \cdot f'(u),
\]
and
\[
|f'(z) - f'(w)| \lesssim |z - w|(|z| + |w|)^{p-1}, \quad p > 1.
\]

The Fourier transform on \( \mathbb{R}^2 \) is defined by
\[
\hat{f}(\xi) := (2\pi)^{-1} \int_{\mathbb{R}^2} e^{-ix \cdot \xi} f(x) dx,
\]
giving rise to the fractional differentiation operators \( |\nabla|^s \) and \( \langle \nabla \rangle^s \) defined by
\[
|\nabla|^s f(\xi) := |\xi|^s \hat{f}(\xi), \quad \langle \nabla \rangle^s f(\xi) := \langle \xi \rangle^s \hat{f}(\xi).
\]
where \( \langle \xi \rangle := 1 + |\xi| \). This helps us to define the homogeneous and inhomogeneous Sobolev norms
\[
\|f\|_{H^s_0(\mathbb{R}^2)} := \| |\xi|^s \hat{f} \|_{L^2_0(\mathbb{R}^2)}, \quad \|f\|_{H^s(\mathbb{R}^2)} := \| \langle \xi \rangle^s \hat{f} \|_{L^2(\mathbb{R}^2)}.
\]
We will also need the Littlewood-Paley projection operators. Let \( \varphi(\xi) \) be a smooth bump function adapted to the ball \( |\xi| \leq 2 \) which equals 1 on the ball \( |\xi| \leq 1 \). For each dyadic number
\(N \in 2^\mathbb{Z}\), we define the Littlewood-Paley operators
\[
P_{\leq N} f(\xi) := \varphi\left(\frac{\xi}{N}\right) \hat{f}(\xi),
\]
\[
P_{> N} f(\xi) := \left(1 - \varphi\left(\frac{\xi}{N}\right)\right) \hat{f}(\xi),
\]
\[
P_N f(\xi) := \left(\varphi\left(\frac{\xi}{N}\right) - \varphi\left(\frac{2\xi}{N}\right)\right) \hat{f}(\xi).
\]
Similarly, we can define \(P_{< N}, P_{\geq N}\), and \(P_M < N = P_{< N} - P_{\leq M}\), whenever \(M\) and \(N\) are dyadic numbers. Especially, we denote \(P_1 := P_{\leq 1}\). We will frequently write \(f_{\leq N}\) for \(P_{\leq N} f\) and similarly for the other operators.

The Littlewood-Paley operators commute with derivative operators, the free propagator, and the conjugation operation. They are self-adjoint and bounded on every space \(L^p_\infty(\mathbb{R}^2)\) and \(\dot{H}^s_x(\mathbb{R}^2)\) for \(1 \leq p \leq \infty\) and \(s \geq 0\). Moreover, they also obey the following Bernstein estimates.

**Lemma 2.1** (Bernstein estimates). For every \(s \geq 0\), \(1 \leq p \leq q \leq \infty\), and \(N \in \mathbb{N}\), we have
\[
\left\|P_{\leq N} f\right\|_{L^p(\mathbb{R}^2)} \lesssim N^{-s} \left\|\nabla^s P_{> N} f\right\|_{L^p(\mathbb{R}^2)},
\]
\[
\left\|\nabla^s P_{\leq N} f\right\|_{L^p(\mathbb{R}^2)} \lesssim N^s \left\|P_{\leq N} f\right\|_{L^p(\mathbb{R}^2)},
\]
\[
\left\|\nabla^s P_N f\right\|_{L^p(\mathbb{R}^2)} \lesssim N^{s+1} \left\|P_N f\right\|_{L^p(\mathbb{R}^2)},
\]
\[
\left\|P_N f\right\|_{L^q(\mathbb{R}^2)} \lesssim N^{s-q} \left\|P_N f\right\|_{L^p(\mathbb{R}^2)}.
\]

**2.2. Strichartz estimates.** Let \(e^{i\tau\Delta}\) be the free Schrödinger propagator given by
\[
[e^{i\tau\Delta}f](x) = \frac{1}{\sqrt{4\pi\tau}} \int e^{i\frac{|x-y|^2}{4\tau}} f(y) \, dy, \quad \tau \neq 0.
\]
Obviously, it satisfies the dispersive estimate
\[
\|e^{i\tau\Delta}f\|_{L^\infty_t L^2_x(\mathbb{R}^2)} \lesssim |\tau|^{-\frac{1}{2}} \|f\|_{L^1_x(\mathbb{R}^2)}, \quad \tau \neq 0.
\]
Interpolating above inequality with \(\|e^{i\tau\Delta}f\|_{L^q_t L^2_x(\mathbb{R}^2)} \equiv \|f\|_{L^q_x(\mathbb{R}^2)}\) then yields
\[
\left\|e^{i\tau\Delta}f\right\|_{L^q_t L^2_x(\mathbb{R}^2)} \leq C|\tau|^{-\frac{1}{2} - \frac{s}{q}} \left\|f\right\|_{L^2_x(\mathbb{R}^2)}, \quad \tau \neq 0
\]
for \(2 \leq q \leq \infty\). This inequality implies the classical Strichartz estimates by the standard \(TT^*\) argument, which we will state below. First, we need the following definition.

**Definition 2.1** (Admissible pairs). A pair of exponents \((q, r)\) is called Schrödinger admissible in \(\mathbb{R}^2\), which we denote by \((q, r) \in \Lambda_0\) if
\[
2 \leq q, r \leq \infty, \quad \frac{1}{q} + \frac{1}{r} = \frac{1}{2}, \quad \text{and} \quad (q, r) \neq (2, \infty).
\]
For a spacetime slab \(I \times \mathbb{R}^2\), we define the Strichartz norm
\[
\|u\|_{S^0(I)} := \sup \left\{ \|u\|_{L^q_t L^r_x(I \times \mathbb{R}^2)} : (q, r) \in \Lambda_0, \quad q \geq 2 + c_0 \right\},
\]
where \(0 < c \ll 1\). We denote \(S^0(I)\) to be the closure of all test functions under this norm.

We now state the standard Strichartz estimates in the form that we will need later.

**Proposition 2.1** (Strichartz estimates [20],[23],[37]). Let \(s \geq 0\) and suppose \(u : I \times \mathbb{R}^2 \to \mathbb{C}\) is a solution to \((i\partial_t + \Delta)u = \sum_{j=1}^m F_j\). Then
\[
\left\|\nabla^s u\right\|_{S^0(I)} \lesssim \left\|\nabla^s u(t_0)\right\|_{L^2_x(\mathbb{R}^2)} + \sum_{j=1}^m \left\|\nabla^s F_j\right\|_{L^q_t L^r_x(I \times \mathbb{R}^2)}
\]
(2.3)
for any admissible pairs \((q_j, r_j)\) and \(t_0 \in I\).

2.3. **Nonlinear estimate.** For \(N > 1\), we define the Fourier multiplier \(I := I_N\) given by
\[
\hat{I}u(\xi) := m(\xi)\hat{u}(\xi),
\]
where \(m(\xi)\) is a smooth radial decreasing cut off function by \((1.10)\). Let us collect basic properties of \(I\).

**Lemma 2.2** ([11]). Let \(1 < p < \infty\) and \(0 \leq \sigma \leq 1\). Then,
\[
\|IF\|_{L^p} \lesssim \|f\|_{L^p},
\]
\[
\|\|\nabla\|^{\sigma} P_{> N}f\|_{L^p} \lesssim N^{\sigma - 1}\|\nabla f\|_{L^p},
\]
\[
\|f\|_{\dot{H}^\sigma} \lesssim \|IF\|_{H^\sigma} \lesssim N^{1 - \sigma}\|f\|_{H^\sigma}.
\]

We will also need the following fractional calculus estimates.

**Lemma 2.3** ([8]).
(i) (Fractional product rule) Let \(s \geq 0\), and \(1 < r, r_j, q_j < \infty\) satisfy
\[
\frac{1}{r} = \frac{1}{r_1} + \frac{1}{r_2},
\]
Then
\[
\|\|\nabla\|^{s} (fg)\|_{L^r((-\infty, \infty)^2)} \lesssim \|f\|_{L^{r_1}((-\infty, \infty)^2)}\|\nabla\|^{s} g\|_{L^{r_2}((-\infty, \infty)^2)} + \|\|\nabla\|^{s} f\|_{L^{r_1}((-\infty, \infty)^2)}\|g\|_{L^{r_2}((-\infty, \infty)^2)}.
\]

(ii) (Fractional chain rule) Let \(G \in C^1(\mathbb{C})\), \(s \in (0, 1]\), and \(1 < r, r_1, r_2 < +\infty\) satisfy
\[
\frac{1}{r} = \frac{1}{r_1} + \frac{1}{r_2}.
\]
Then
\[
\|\|\nabla\|^{s} G(u)\|_{r} \lesssim \|G'(u)\|_{r_1}\|\nabla\|^{s} u\|_{r_2}.
\]

As noted in the introduction, one needs to estimate the commutator \(|Iu|^p Iu - I(|u|^p u)\) in the increment of modified energy \(E(Iu(t))\). When \(p\) is an even integer, one can use multilinear analysis to expand this commutator into a product of Fourier transforms of \(u\) and \(Iu\), and carefully measure frequency interactions to derive an estimate (see for example [8]). However, this is not possible when \(p\) is not an even integer. Instead, Visan and Zhang in [11] established the following rougher estimate:

**Lemma 2.4** ([11]). Let \(1 < r, r_1, r_2 < \infty\) be such that \(\frac{1}{r} = \frac{1}{r_1} + \frac{1}{r_2}\) and let \(0 < \nu < s\). Then,
\[
\|I fg - (I f) g\|_{L^r} \lesssim N^{-(1 - s + \nu)}\|I f\|_{L^{r_1}}\|\nabla\|^{1 - s + \nu} g\|_{L^{r_2}}.
\]
Furthermore, we have
\[
\|\nabla I f(u) - (\nabla I u) f' (u)\|_{L^r} \lesssim N^{-(1 - s + \nu)}\|\nabla I u\|_{L^{r_1}}\|\nabla\|^{1 - s + \nu} f' (u)\|_{L^{r_2}},
\]
and
\[
\|\nabla I f(u)\|_{L^r} \lesssim \|\nabla I u\|_{L^{r_1}}\|f' (u)\|_{L^{r_2}} + N^{-(1 + s - \nu)}\|\nabla I u\|_{L^{r_1}}\|\nabla\|^{1 - s + \nu} f' (u)\|_{L^{r_2}}.
\]

Finally, we conclude this section by recalling the interaction Morawetz estimate for a solution to problem \((1.1)\).

**Lemma 2.5** (Interaction Morawetz estimates [8] [39]). Let \(u\) be an \(H^\frac{d}{2}\)-solution to \((1.1)\) on the spacetime slab \(I \times \mathbb{R}^2\). Then, for any \(t_0 \in I\), we have
\[
\|u\|^4_{L^4_t L^8_x(I \times \mathbb{R}^2)} \lesssim \|u(t_0)^2\|_{L^4_t(\mathbb{R}^n)}^2.
\]
Moreover, interpolating with \(\|u\|_{L^\infty_t L^2_x}\), we obtain
\[
\|u\|_{L^6_t L^6_x(I \times \mathbb{R}^2)} \lesssim \|u(t_0)^3\|_{L^6_t(\mathbb{R}^n)}^2.
\]

**Remark 2.1.** We adopt the \(L^6_t L^6_x\) interaction Morawetz norm, but not the \(L^4_t L^8_x\)-norm as used in [5]. As we will see in the next section, one needs more restriction on \(p\) to use the \(L^4_t L^8_x\) norm instead of the \(L^6_t L^6_x\) norm. We refer reader to Remark [7] for more details.
To treat the case of low power $p$, we also need the following improved interaction Morawetz inequalities.

**Lemma 2.6 (Improved interaction Morawetz estimates)**. Let $u$ be an $H^\frac{3}{2}$-solution to \( (1.1) \) on the spacetime slab $I \times \mathbb{R}^2$. Then, for any $t_0 \in I$

$$\|u(t, x)\|_{L^4_t(L^\infty_x(I \times \mathbb{R}^2))}^4 \lesssim T^\frac{1}{2}\|u\|_{L^2_{t,x}(I, H^1_x(\mathbb{R}^2))}^2 \|u(t_0)\|_2^2 + T^\frac{1}{2}\|u(t_0)\|_2^4. \tag{2.14}$$

### 3. Proof of Theorem 1.1

In this section, we will use the I-method and the interaction Morawetz estimate to prove Theorem 1.1. At the first step, we need to show that the modified energy $E(Iu)$

$$E(Iu)(t) = \frac{1}{4} \int_{\mathbb{R}^2} |\nabla Iu(t)|^2 + \frac{1}{p+2} \int_{\mathbb{R}^2} |Iu(t)|^{p+2} \tag{3.1}$$

is an “almost conserved” quantity in the sense that its derivative decays with respect to $N$. In the following, we always assume $s < 1$.

#### 3.1. Almost Conservation Law

The aim of this subsection is to control the growth in time of $E(Iu)(t)$. First, we define $Z_1(t)$ by

$$Z_1(t) := \|Iu\|_{Z(t)} = \sup_{(q,r) \in \Lambda_0} \left( \sum_{N \geq 1} \|\nabla P_N Iu(t)\|_{L^q(L^r(I \times \mathbb{R}^2)))}^2 \right)^{\frac{1}{2}}. \tag{3.2}$$

with convention that $P_1 = P_{\leq 1}$. We have the following control of $Z_1(t)$.

**Proposition 3.1 (The control of $Z_1(t)$)**. Let $u(t, x)$ be an $H^s$ solution to problem \( (1.1) \) with $f(u) = |u|^p u$ defined on $[t_0, T] \times \mathbb{R}^2$ and such that

$$\|u\|_{L^\infty_t([t_0, T] \times \mathbb{R}^2)} \lesssim \eta \tag{3.3}$$

for some small constant $\eta$. Assume $E(Iu(t_0)) \leq 1$. Then for $s > \frac{2+\frac{\alpha}{\alpha+4}}{2}$, $p \geq \frac{5}{2}$, and sufficiently large $N$, we have for any $t \in [t_0, T]$

$$Z_1(t) \lesssim \|\nabla Iu(t_0)\|_2 + g(t)Z_1(t) + N^{-(s-s_2)}Z_1(t)g(t)^{p-1}[g(t) + h(t)], \tag{3.4}$$

where $g(t)$ and $h(t)$ are defined as follows:

$$g(t)^p = \eta^{\theta_1} \sup_{s \in [t_0, t]} E(Iu(s))^{\frac{1-\theta_1}{p+2}} + \eta^{\theta_2} Z_1(t)^{(1-\theta_2)p} + N^{-(1-s_2)p}Z_1(t)^p \tag{3.5}$$

and

$$h(t) = \eta^{\theta_1} \sup_{s \in [t_0, t]} E(Iu(s))^{\frac{1-\theta_1}{p+2}} + Z_1(t) \tag{3.6}$$

with $\theta_1 = \frac{\alpha}{2p}$, $\theta_2 = \frac{\alpha}{2(p+2)} \in (0, 1)$.

**Proof.** Applying the operator $I$ to \( (1.1) \) and using the Strichartz estimate, we obtain for all $t \in [t_0, T]$

$$Z_1(t) \lesssim \|\nabla Iu(t_0)\|_2 + \|\nabla I f(u)\|_{L^4_{t,x}(I \times \mathbb{R}^2)} \lesssim \|\nabla Iu(t_0)\|_2 + \|\nabla I f(u)\|_{L^4_{t,x}(I \times \mathbb{R}^2)} \lesssim \|\nabla Iu(t_0)\|_2 + |I_1 + I_2. \tag{3.7}$$

Throughout the following proof all spacetime norms will be computed on $[t_0, t] \times \mathbb{R}^2$. 

• The estimate of the term $II_1$: Using the Hölder and Minkowski inequalities, we get

$$II_1 = \| (\nabla I u) f'(u) \|_{L^2_{t,x}} \lesssim \| \nabla I u \|_{L^2_{t,x}} \| u \|_{L^p_{t,x}} \lesssim Z_1(t) \| u \|^p_{L^p_{t,x}}. \quad (3.8)$$

It remains to estimate $\| u \|^p_{L^p_{t,x}}$. We decompose $u = u_{<1} + u_{1<} + u_{>N} + u_{>N}$. We estimate the low frequency part by an interpolation and the Bernstein inequality

$$\| u_{<1} \|^p_{L^p_{t,x}} \lesssim \| u_{<1} \|_{L^p_{t,x}}^{(1-\theta_1)p} \| u_{<1} \|_{L^p_{t,x}}^{(1-\theta_2)p} \lesssim \eta^{\theta_2p} \| u \|^{(1-\theta_1)p}_{L^p_{t,x}} \lesssim \eta^{\theta_2p} \| u \|^{(1-\theta_1)p}_{L^p_{t,x}}, \quad (3.9)$$

where we have used the condition $p \geq \frac{5}{4}$ and $\theta_1 = \frac{5}{2p}$.

For the medium frequency part, we use an interpolation, the Sobolev embedding and the Bernstein inequality to estimate

$$\| u_{1<} \|^p_{L^p_{t,x}} \lesssim \| u_{1<} \|_{L^p_{t,x}}^{(1-\theta_2)p} \| u_{1<} \|_{L^p_{t,x}}^{(1-\theta_3)p} \lesssim \eta^{\theta_3p} \| \nabla \|_{L^p_{t,x}}^{(1-\theta_2)p} u_{1<} \|_{L^p_{t,x}}^{(1-\theta_3)p} \lesssim \eta^{\theta_3p} \| u \|^{(1-\theta_2)p}_{L^p_{t,x}} \| u \|^{(1-\theta_3)p}_{L^p_{t,x}}, \quad (3.10)$$

where $\theta_2 = \frac{5}{2(3p-5)}$ and $(3p, \frac{6p}{3p-2}) \in \Lambda_0$.

For the high frequency part, we use Sobolev embedding and (2.5) with $\sigma = s_c$ to obtain

$$\| u_{>N} \|^p_{L^p_{t,x}} \lesssim \| \nabla \|^{s_c} u_{>N} \|^p_{L^p_{t,x}} \lesssim N^{-(1-s_c)p} \| \nabla I u \|^p_{L^p_{t,x}} \lesssim N^{-(1-s_c)p} Z_1(t)^p. \quad (3.11)$$

Thus, collecting (3.8)- (3.11) yields

$$\| u \|^p_{L^p_{t,x}} \lesssim g(t)^p,$$

and so

$$II_1 \lesssim Z_1(t) g(t)^p. \quad (3.12)$$

• The estimate of the term $II_2$: By the assumption $s > \frac{1+s_c}{2}$, we have $\nu := 2s-s_c - 1 < s$. Thus, we deduce from Lemma 2.3, 3.12 and 2.10

$$II_2 = \| \nabla I f(u) - (\nabla I u) f'(u) \|_{L^2_{t,x}} \lesssim N^{-(s-s_c)} \| \nabla I u \|^s_{L^2_{t,x}} \| (\nabla)^{s-s_c} f'(u) \|_{L^2_{t,x}}$$

$$\lesssim N^{-(s-s_c)} Z_1(t) \left( \| f'(u) \|_{L^2_{t,x}} + \| (\nabla)^{s-s_c} f'(u) \|_{L^2_{t,x}} \right)$$

$$\lesssim N^{-(s-s_c)} Z_1(t) \left( \| u \|^p_{L^p_{t,x}} + \| u \|^p_{L^p_{t,x}} \| (\nabla)^{s-s_c} u \|_{L^p_{t,x}} \right)$$

$$\lesssim N^{-(s-s_c)} Z_1(t) g(t)^{p-1} [g(t) + \| (\nabla)^{s-s_c} u \|_{L^p_{t,x}}]$$

$$\lesssim N^{-(s-s_c)} Z_1(t) g(t)^{p-1} [g(t) + h(t)], \quad (3.13)$$
where we have used the same argument as deriving (3.12) to estimate
\[
\|\nabla^{s-x} u\|_{L^p_t L^r_x} \lesssim \|u\|_{L^p_t L^r_x} + \|\nabla^{s-x} u\|_{L^p_t L^r_x} + \|\nabla^{s-x} u\|_{L^p_t L^r_x} \\
\lesssim \|u\|_{L^p_t \mathcal{L}^\infty} + \|\nabla u\|_{L^p_t L^r_x} + \|\nabla u\|_{L^p_t L^r_x} \\
\lesssim \eta^\theta \sup_{s \in [0, t]} E(Iu(s))^{\frac{1-\theta_3}{p-1}} + Z_1(t) + N^{s-1} Z_5(t) \\
\lesssim h(t). \tag{3.14}
\]
This estimate together with inequality (3.12) ends the proof of Proposition 3.1. \(\square\)

**Remark 3.1.** We assume the \(L^1_t L^8_x\) interaction Morawetz norm to be small unlike the small interaction Morawetz norm \(L^4_t L^8_x\) as used in [2]. If we replace (3.3) by
\[
\|u\|_{L^p_t L^5_x([0,T] \times \mathbb{R}^2)} \lesssim \eta, \tag{3.15}
\]
then, by the similar argument as above, we need the estimate
\[
\|\nabla u\|_{L^p_t \mathcal{L}^\infty} \lesssim \|\nabla u\|_{L^p_t L^r_x}, \quad \text{for} \quad (q, r) \in \Lambda_0, \quad \theta \in [0, 1]
\]
together with the low frequency part
\[
\|u\|_{L^p_t L^5_x} \lesssim \|u\|_{L^p_t L^5_x}, \quad \text{where we need the restriction} \quad \frac{p}{q} \geq 4 \quad \text{and} \quad \frac{1}{r} \geq 8. \quad \text{Therefore,}
\]
\[
p \geq \min_{0 \leq \theta \leq 1} \max \{4\theta, 8(1 - \theta)\} = \frac{8}{3}.
\]
This argument, compared with \(p \geq \frac{8}{5}\) in Proposition 3.1, shows that \(L^5_t L^8_x\) is better than \(L^4_t L^8_x\).

Next, we show the energy increment of \(E(Iu(t))\).

**Proposition 3.2 (Energy increment).** Let \(u(t, x)\) be an \(H^s\) solution to (1.1) with \(f(u) = |u|^{p-1} u\) defined on \([0, T] \times \mathbb{R}^2\), which satisfies
\[
\|u\|_{L^1_t L^8_x([0, T] \times \mathbb{R}^2)} \lesssim \eta \tag{3.16}
\]
for some small constant \(\eta\). Assume \(E(Iu(t_0)) \leq 1\). Then for \(s \geq \frac{p}{p-1} \), \(p \geq \frac{1}{4}\) and sufficiently large \(N\), we have for any \(t \in [0, T]\)
\[
\left| \sup_{s \in [0, t]} E(Iu(s)) - E(Iu(t_0)) \right| \lesssim N^{-s} Z_1(t)^3 g(t)^{p-1} + N^{-s} Z_5(t)^2 g(t)^{p-1} \left[ g(t) + h(t) \right] \\
+ k(t) \left\{ N^{-1} g(t)^p Z_1(t) + \eta N^{-s} g(t)^p m(t) \right\},
\]
where \(k(t)\) and \(m(t)\) are defined by
\[
k(t) = \eta^{\theta_2} \sup_{s \in [0, t]} E(Iu(s))^{\frac{1-\theta_3}{p+1}} + Z_1(t)^{\theta_3}, \quad \theta_3 = \frac{5}{4(p+1)}
\]
and
\[
m(t) = \eta^{1+\theta_4} g(t)^{(1-\theta_4)(p-1)} \left( \eta^{\theta_1} g(t)^{1-\theta_4} + Z_1(t) \right)
\]
with \(\theta_4 = \frac{1}{4p-10}\) and \(q = \frac{5p}{11}\).
Proof. Since $iIu_t + \Delta Iu = IF(u)$, we get by a simple computation

$$E(Iu(t)) - E(Iu(t_0)) = \int_{t_0}^t \frac{\partial}{\partial s} E(Iu(s)) ds$$

$$= \text{Re} \int_{t_0}^t \int_{\mathbb{R}^a} Tu(t) (\Delta Iu + f(Iu)) dx ds$$

$$= \text{Re} \int_{t_0}^t \int_{\mathbb{R}^a} Tu[t] (f(Iu) - I f(u)] dx ds$$

$$= - \text{Im} \int_{t_0}^t \int_{\mathbb{R}^a} \nabla Iu \cdot \nabla [f(Iu) - I f(u)] dx ds$$

$$= - \text{Im} \int_{t_0}^t \int_{\mathbb{R}^a} I^2(f(u) - f(u)) dx ds$$

$$= - \text{Im} \int_{t_0}^t \int_{\mathbb{R}^a} [\nabla Iu f' - I f' u] \nabla dx ds$$

$$= - \text{Im} \int_{t_0}^t \int_{\mathbb{R}^a} I^2(f(u)) - f(u)] dx ds$$

$$\triangleq I_{I1} + I_{I2} + I_{I3}.$$

• The estimate of $I_{I1}$: Since $(2p, \frac{2p}{p-1}) \in \Lambda_0$, by inequality [2.5] with $\sigma = s_c$, and the Sobolev embedding, we estimate

$$|I_{I1}| \leq \|\nabla Iu\|_{L^2(t)}^2 \|f'(Iu) - f'(u)\|_{L^2(t)}$$

$$\leq Z_1(t)^2 \|P_{> N} u\|_{L^2(t)}^p \|u\|_{L^2(t)}^{p-1}$$

$$\leq Z_1(t)^2 \|\nabla \|_{L^2(t)}^p \|u\|_{L^2(t)}^{p-1}$$

$$\leq Z_1(t)^2 N^{-(1-s_c)} \|\nabla Iu\|_{L^2(t)}^p \|g(t)\|^{p-1}$$

$$\leq N^{-(1-s_c)} Z_1(t)^3 g(t)^{p-1}.$$ (3.18)

• The estimate of $I_{I2}$: Using Hölder’s inequality and [3.15], we obtain

$$|I_{I2}| \leq \|\nabla Iu\|_{L^4(t)} \|f'(Iu) - f'(u)\|_{L^4(t)}$$

$$\leq N^{-(1-s_c)} Z_1(t)^3 g(t)^{p-1}.$$ (3.19)

• The estimate of $I_{I3}$: By Hölder’s inequality and Minkowski’s inequality, we get

$$|I_{I3}| \leq \|If(u)\|_{L^4(t)} \||f(Iu) - I f(u)\|_{L^4(t)}$$

$$\leq \|u\|_{L^4(t)} \left\{ \|u\|_{L^4(t)}^{p+1} + \|u\|_{L^4(t)}^{p} \right\}.$$ (3.20)

To estimate $\|u\|_{L^4(t)}^{p+1}$, we decompose $u = u_{\leq 1} + u_{1 \leq N} + u_{> N}$. Using the same argument as leading to [3.12] and $(4(p + 1), \frac{4(p + 1)}{2p+1}) \in \Lambda_0$, one has the inequality by means of [2.5] with
\[ \sigma = \frac{p}{p+1}, \]
\[ \|u\|_{L_{t,x}^{p+1}}^{p+1} \lesssim \|u_{1\leq N}\|_{L_{t,x}^{p+1}}^{p+1} + \|u_{N+1}\|_{L_{t,x}^{p+1}} \]
\[ \lesssim \|u\|_{L_{t,x}^{(1-\theta_3)(p+1)}}^{\theta_3(p+1)} + \|\nabla u\|_{L_{t,x}^{(p+1)}} \lesssim \eta \lesssim \|\nabla Iu\|_{L_{t,x}^{(p+1)}} \]
\[ \lesssim \eta^{\theta_3(p+1)} \|u\|_{L_{t,x}^{p+1}} \lesssim \|\nabla Iu\|_{L_{t,x}^{p+1}} \]
\[ \approx k(t), \]

where \( \theta_3 = \frac{5}{4(p+1)} \) and where we have used the condition \( s \geq \frac{p}{p+1} \).

To estimate \( \|Iu([u]^p - |u|^p)\| \), we use Hölder’s inequality, to get
\[ \|Iu([u]^p - |u|^p)\| \lesssim \|Iu\|_{L_{t,x}^{p}} \|u\|_{L_{t,x}^{p+1}} \lesssim \|u\|_{L_{t,x}^{p+1}} \|\nabla Iu\|_{L_{t,x}^{p+1}} \]
\[ \lesssim N^{-1} g(t)^p Z(t). \]

To estimate \( \|(|Iu)|u|^p - I(|u|^p)u\| \), using (2.9) with \( \nu = 2s - \frac{3}{2} + \frac{1}{q} \in (0, s) \) and (2.8), we obtain for \( q = \frac{5p}{11} \)
\[ \|(|Iu)|u|^p - I(|u|^p)u\| \]
\[ \lesssim N^{-(s-\frac{1}{2} + \frac{1}{q})} g(t)^p \|\nabla Iu\|_{L_{t,x}^{p+1}} \lesssim \eta^{\theta_4} \|\nabla Iu\|_{L_{t,x}^{p+1}} \]
\[ \lesssim \eta^{\theta_4} g(t)^{1-\theta_4} + Z(t) \]
\[ \approx k(t) \]

where we have used the estimates
\[ \|u\|_{L_{t,x}^{p+1}} \lesssim \|u\|_{L_{t,x}^{p+1}} \|u\|_{L_{t,x}^{p+1}} \lesssim \eta^{\theta_4} g(t)^{1-\theta_4}, \quad \theta_4 = \frac{1}{4q-10} \]
and
\[ \|\nabla Iu\|_{L_{t,x}^{p+1}} \lesssim \|\nabla Iu\|_{L_{t,x}^{p+1}} \|\nabla Iu\|_{L_{t,x}^{p+1}} \lesssim \eta^{\theta_4} g(t)^{1-\theta_4} + Z(t) \]
\[ \approx k(t) \]

with \( r = \frac{20p}{11q}, \quad (4q, r) \in \mathbb{A}_0. \) Since inequality \( p \geq \frac{11}{4} \) guarantees \( 4q \geq 5 \), the interpolation inequality in (3.23) is valid. Thus, plugging (3.21), (3.22) into (3.23), we get
\[ \|Iu\| \lesssim k(t) \left\{ N^{-1} g(t)^p Z(t) + N^{-(s-\frac{1}{2} + \frac{1}{q})} m(t) \right\}. \]

This estimate, together with (3.18), (3.19), yields (3.17).
Now we use a standard bootstrap argument to show that the quantity $E(Iu(t))$ is “almost conserved” by making use of inequality

$$s - s_c \leq \min\{1 - s_c, s - \frac{1}{2}, \frac{1}{2} + \frac{1}{q}\}.$$

**Proposition 3.3** (Almost conservation law). Let $u(t, x)$ be an $H^s$ solution to problem (1.1) with $f(u) = |u|^p u$ defined on $[t_0, T] \times \mathbb{R}^2$ and satisfy

$$\|u\|_{L^5_t([t_0, T] \times \mathbb{R}^2)} \leq \eta$$

for some small constant $\eta$. Assume $E(Iu(t_0)) \leq 1$. Then for

$$s \geq \max \left\{ \frac{1 + s_c}{2}, \frac{p}{p + 1} \right\}, \quad p \geq \frac{11}{4}$$

and sufficiently large $N$, we have

$$E(Iu(t)) = E(Iu(t_0)) + O(N^{s_c - s}).$$

(3.27)

**Proof.** Expression (3.27) will follow from Proposition 3.1 and 3.2 provided we establish

$$Z_1(t) \lesssim 1 \quad \text{and} \quad \sup_{s \in [t_0, t]} E(Iu(s)) \lesssim 1, \quad \forall \ t \in [t_0, T].$$

(3.28)

From the assumption $E(Iu(t_0)) \leq 1$, we only need to prove that

$$Z_1(t) \lesssim \|\nabla Iu(t_0)\|_2, \quad \forall \ t \in [t_0, T]$$

(3.29)

and

$$\sup_{s \in [t_0, t]} E(Iu(s)) \lesssim E(Iu(t_0)), \quad \forall \ t \in [t_0, T].$$

(3.30)

We show it by a standard bootstrap argument. It suffices to show that the above two properties hold on the interval $[t_0, T]$. Let

$$\Omega_1 := \{t \in [t_0, T] : Z_1(t) \leq C_1 \|\nabla Iu(t_0)\|_2, \sup_{s \in [t_0, t]} E(Iu(s)) \leq C_2 E(Iu(t_0))\},$$

$$\Omega_2 := \{t \in [t_0, T] : Z_1(t) \leq 2C_1 \|\nabla Iu(t_0)\|_2, \sup_{s \in [t_0, t]} E(Iu(s)) \leq 2C_2 E(Iu(t_0))\};$$

where $C_1$ and $C_2$ are sufficiently large constants which may depend on the Strichartz constant.

In order to run the bootstrap argument successfully, we need to verify three properties:

1. $\Omega_1$ is a nonempty closed set.
2. $\Omega_2 \subset \Omega_1$.
3. If $t \in \Omega_1$, then there exists $\varepsilon > 0$ such that $[t, t + \varepsilon) \subset \Omega_2$.

In fact, since $t_0 \in \Omega_1$, one easily verifies $\Omega_1$ is a nonempty closed by Fatou’s Lemma. Combining Proposition 3.1 and 3.2 yields (2) by taking $N$ sufficiently large and $\eta$ sufficiently small depending on $C_1$, $C_2$ and $E(Iu(t_0))$. Property (3) follows from (2) and from the local well-posedness theory.

The last two statements show that $\Omega_1$ is open from the right-hand side and Proposition 3.3 is proved. 

□
3.2. Global well-posedness. In this part, we establish the global time-space estimates in terms of a rough norm of initial data by making use of the interaction Morawetz estimate and almost conservation law with a scaling argument.

**Proposition 3.4.** Suppose \( u(t,x) \) is a global solution to problem (1.1) with \( f(u) = |u|^pu \) satisfying \( u_0 \in C_0^\infty(\mathbb{R}^2) \). Then for

\[
\max \left\{ \frac{p}{p+1}, \frac{1+s_c}{2}, s_1 \right\} < 1 \text{ and } p \geq \frac{11}{4},
\]

we have

\[
\|u\|_{L^p_t(L^2_x(\mathbb{R}^2))} \leq C\left(\|u_0\|_{H^s(\mathbb{R}^2)}\right),
\]

\[
\sup_{t \in \mathbb{R}} \|u(t)\|_{H^s(\mathbb{R}^2)} \leq C\left(\|u_0\|_{H^s(\mathbb{R}^2)}\right),
\]

where \( s_1 \) is the positive root of the quadratic equation

\[
s^2 + 2s_c s + s_c^2 - 4s_c = 0.
\]

**Remark 3.2.** From the local well-posedness theory, we know that the lifespan of a local solution depends only on the \( H^s \)-norm of the initial data. Thus, the global well-posedness part of Theorem 3.1 follows from (3.32) and the standard density argument.

**Proof of Proposition 3.4.** If \( u \) is a solution to problem (1.1) with \( f(u) = |u|^pu \), so is

\[
u^\lambda(t,x) = \lambda^{-\frac{2}{p+2}}u(\frac{t}{\lambda^2}, \frac{x}{\lambda}).
\]

By inequality (2.5) and the Sobolev embedding, we have

\[
\|\nabla I_{u_0}^\lambda\|_{L^2(\mathbb{R}^2)} \lesssim N^{1-s}\|u_0^\lambda\|_{H^s} \simeq N^{1-s}\lambda^{s-c} \|u_0\|_{H^s},
\]

\[
\|I_{u_0}^\lambda\|_{L^{p+2}} \lesssim \|u_0^\lambda\|_{L^{p+2}} = \lambda^{-\frac{2}{p+2} + \frac{s}{p+2}} \|u_0\|_{L^{p+2}} \lesssim \lambda^{-\frac{2}{p+2} + \frac{s}{p+2}} \|u_0\|_{H^s}.
\]

As \( s > s_c \), taking \( \lambda \) sufficiently large depending on \( \|u_0\|_{H^s} \) and \( N \) such that

\[
N^{1-s}\lambda^{s-c} \|u_0\|_{H^s} \ll 1 \quad \text{and} \quad \lambda^{-\frac{2}{p+2} + \frac{s}{p+2}} \|u_0\|_{H^s} \ll 1,
\]

we get

\[
E(I_{u_0}^\lambda) \ll 1.
\]

Next, we claim that there exists an absolute constant \( C \) such that

\[
\|u^\lambda\|_{L^p_t(L^2_x(\mathbb{R}^2))} \lesssim C\lambda^{s_c}.
\]

Choosing \( \lambda = 1 \) yields (3.31). We prove inequality (3.36) via a bootstrap argument. By time reversal symmetry, it suffices to argue for positive time only. Define

\[
\Omega_1 := \{ t \in [0, \infty) : \|u^\lambda\|_{L^p_t(L^2_x([0,t] \times \mathbb{R}^2))} \lesssim C\lambda^{s_c} \}.
\]

Our goal is to prove \( \Omega_1 = [0, \infty) \). Let

\[
\Omega_2 := \{ t \in [0, \infty) : \|u^\lambda\|_{L^p_t(L^2_x([0,t] \times \mathbb{R}^2))} \lesssim 2C\lambda^{s_c} \}.
\]

In order to run the bootstrap argument successfully, we need to check the following properties:

1. \( \Omega_1 \) is a nonempty closed (as \( 0 \in \Omega_1 \) and using Fatou’s Lemma);
2. \( \Omega_2 \subset \Omega_1 \);
3. If \( t \in \Omega_1 \), then there exists \( \varepsilon > 0 \) such that \( [t, t + \varepsilon) \subset \Omega_2 \).
Property (3) follows from (2) and the local well-posedness theory. Thus, it suffices to prove (2): For any $T \in \Omega_2$, we want to show that $T \in \Omega_1$. Throughout the following proof, all the space-time norms will be computed on $[0, T] \times \mathbb{R}^2$.

Using the interaction Morawetz estimate and the mass conservation, we get
\[
\|u^\lambda\|_{L^5_t L^6_x} \lesssim \|u_0^\lambda\|_2 \|u^\lambda\|_{L^6_t H^\frac 52} \lesssim \lambda^{\frac 72 c} \|u_0\|_2 \|u^\lambda\|_{L^6_t H^\frac 52},
\] (3.37)

To control the term $\|u^\lambda(t)\|_{L^6_t H^\frac 52}$, we decompose $u^\lambda = P_{\leq N} u^\lambda + P_{> N} u^\lambda$.

For the low frequency part, we interpolate between the $L^2$-norm and $\dot{H}^1$-norm and we use the fact that the operator $I$ is the identity on frequencies $|\xi| \leq N$:
\[
\|P_{\leq N} u^\lambda\|_{H^\frac 52} \lesssim \|P_{\leq N} u^\lambda\|_2 \|P_{\leq N} u^\lambda\|_{\dot{H}^1} \lesssim \lambda^{\frac 72 c} \|u_0\|_2 \|u^\lambda\|_{\dot{H}^1}.
\] (3.38)

To estimate the high frequency part, we interpolate between the $L^2$-norm and $\dot{H}^s$-norm and use (2.3) and (3.34) to obtain
\[
\|P_{> N} u^\lambda\|_{H^\frac 52} \lesssim \|P_{> N} u^\lambda\|_2 \|P_{> N} u^\lambda\|_{\dot{H}^1} \lesssim \lambda^{(1-\frac 1s)c} \|u_0\|_2 \|u^\lambda\|_{\dot{H}^1} \lesssim \lambda^{s_c - \frac 52} \|u_0\|_2 \|u^\lambda\|_{\dot{H}^1},
\] (3.39)

Plugging (3.38) and (3.39) into (3.37), we estimate
\[
\|u^\lambda\|_{L^5_t L^6_x} \lesssim \lambda^{\frac 72 c} \|u_0\|_2 \|u^\lambda\|_{L^6_t H^\frac 52} \lesssim \lambda^{\frac 72 c} \|u_0\|_2 \sup_{s \in [0, T]} \left( (\lambda^{\frac 72 c} \|u_0\|_2 \|u^\lambda\|_{\dot{H}^1} + \lambda^{s_c - \frac 52} \|u_0\|_2 \|u^\lambda\|_{\dot{H}^1}) \right)^{\frac 58}
\]
\[
\lesssim C(\|u_0\|_2) \lambda^{\frac 72 c} \sup_{s \in [0, T]} \left( \|u^\lambda\|_{\dot{H}^1} \right)^{\frac 58}
\]
where we have used the fact $\lambda \gg 1$ in the last inequality. Thus, choosing $C$ sufficiently large depending on $\|u_0\|_2$, we obtain $T \in \Omega_1$ provided we can prove
\[
\sup_{s \in [0, T]} \|u^\lambda\|_{\dot{H}^1} \leq 1, \quad T \in \Omega_2.
\] (3.40)

In fact, let $\eta > 0$ be sufficiently small constant as in Proposition 5.3 and we divide $[0, T]$ into subintervals $I_j = [t_j, t_{j+1}]$ such that
\[
\|u^\lambda\|_{L^5_t L^6_x(I_j \times \mathbb{R}^2)} \leq \eta.
\] (3.42)

Using Proposition 5.3 on each interval $I_j$, we obtain
\[
\sup_{t \in [0, T]} E(Iu^\lambda(t)) \leq E(Iu^\lambda_0) + LN^{s_c - s}.
\] (3.43)

To control the changes of energy during the iteration, we need
\[
LN^{s_c - s} \lesssim \lambda^{4s_c} N^{s_c - s} \ll 1.
\]

This fact together with (3.44) leads to
\[
N^{4s_c} \lesssim N^{s_c - s} \ll 1.
\]
This may be ensured by taking \( N = N(\|u_0\|_{H^s}) \) large enough provided that \( s \) satisfies
\[
s^2 + 2s + s^2 - 4s > 0.
\]
This can be verified by \( s > s_1 \) by the definition of \( s_1 \). This completes the bootstrap argument, hence we prove the claim (3.36), and moreover, (3.31) follows.

To deal with \( \|u(t)\|_{H^s} \), by the conservation of mass, and inequalities (2.30) and (3.30), we estimate
\[
\|u(t)\|_{H^s} \lesssim \|u_0\|_{L^2} + \|u(t)\|_{H^s},
\]
\[
\lesssim \|u_0\|_{L^2} + \lambda^{s-s_c} \|u(\lambda^2 t)\|_{H^s},
\]
\[
\lesssim \|u_0\|_{L^2} + \lambda^{s-s_c} \|Iu(\lambda^2 t)\|_{H^s},
\]
\[
\lesssim \|u_0\|_{L^2} + \lambda^{s-s_c} (\|u_0\|_2 + \|Iu(\lambda^2 t)\|_{H^s})
\]
\[
\lesssim \|u_0\|_{L^2} + \lambda^{s-s_c} (\lambda^s \|u_0\|_2 + 1)
\]
\[
\leq C(\|u_0\|_{H^s}).
\]
This completes the proof of (3.32).

\[\square\]

3.3. Scattering. We prove that the scattering part of Theorem 11 holds for \( H^s_\Lambda(\mathbb{R}^2) \) with \( s \in (s_0, 1) \). We first show that the global Morawetz estimate can be improved to the global Strichartz estimate
\[
\|\langle \nabla \rangle^s u\|_{L^2_t L^p_x((\mathbb{R} \times \mathbb{R}^2))} := \sup_{(\eta, \nu) \in \Lambda_0} \|\langle \nabla \rangle^s u\|_{L^2_t L^p_x((\mathbb{R} \times \mathbb{R}^2))}, \tag{3.44}
\]
Second, we use this estimate to show the asymptotic completeness property. Since the construction of the wave operator is standard, we omit it here.

Let \( u \) be a global solution to problem (1.1). From the interaction Morawetz estimate (3.31), we have
\[
\|u\|_{L^p_{t,x}(\mathbb{R} \times \mathbb{R}^2)} \leq C(\|u_0\|_{H^s}). \tag{3.45}
\]
Let \( \eta > 0 \) be a small constant to be chosen later and split \( \mathbb{R} \) into \( L = L(\|u_0\|_{H^s}) \) subintervals \( I_j = [t_j, t_{j+1}) \) such that
\[
\|u\|_{L^p_{t,x}(I_j \times \mathbb{R}^2)} \leq \eta. \tag{3.46}
\]
Using (2.8) and (3.32), One gets
\[
\|\langle \nabla \rangle^s u\|_{L^p_{t,x}(I_j)} \lesssim \|u(t_j)\|_{H^s} + \|\langle \nabla \rangle^s |u|^p u\|_{L^{2p}_{t,x}(I_j \times \mathbb{R}^2)}
\]
\[
\lesssim C(\|u_0\|_{H^s}) + \|u\|_{L^2_{t,x}(I_j \times \mathbb{R}^2)} \|\langle \nabla \rangle^s u\|_{L^4_{t,x}(I_j \times \mathbb{R}^2)}. \tag{3.47}
\]
We use the interpolation and the Sobolev embedding to estimate
\[
\|u\|_{L^p_{t,x}(I_j \times \mathbb{R}^2)} \lesssim \|u\|_{L^p_{t,x}(I_j \times \mathbb{R}^2)} \|\langle \nabla \rangle^s u\|_{L^{1+\theta_2}_{t,x}(I_j \times \mathbb{R}^2)}
\]
\[
= \|u\|_{L^p_{t,x}(I_j \times \mathbb{R}^2)} \|\lambda^{-\theta_2} u\|_{L^{1+\theta_2}_{t,x}(I_j \times \mathbb{R}^2)}
\]
\[
\lesssim \eta \|u\|_{L^p_{t,x}(I_j \times \mathbb{R}^2)} \|\langle \nabla \rangle^s u\|_{L^{1+\theta_2}_{t,x}(I_j \times \mathbb{R}^2)}, \theta_2 = \frac{5}{3p - 2p},
\]
where \( (3p, \frac{6p}{3p-2}) \in \Lambda_0 \), and we have used the fact \( s > \frac{1-s_c}{2} > 1 - \frac{4}{3p} \). Hence,
\[
\|\langle \nabla \rangle^s u\|_{S^0(I_j)} \lesssim C(\|u_0\|_{H^s}) + \eta^{\frac{2}{s_c}} \|\langle \nabla \rangle^s u\|_{S^0(I_j)}^{p - \frac{2}{s_c}}. \tag{3.48}
\]
Proposition 4.1
(The control of $u$) Let $u(t, x)$ be an $H^s$ solution to problem (1.1) with $f(u) = |u|^p u$ defined on $[t_0, T] \times \mathbb{R}^2$ and satisfying

$$\|u\|_{L^4_{t,x}([t_0,T] \times \mathbb{R}^2)} \leq \eta$$

(4.2)

for some small constant $\eta$. Assume $E(Iu(t_0)) \leq 1$. Then for $s > \frac{1+\epsilon_0}{2}$, $p \geq 2$ and sufficiently large $N$, we have for any $t \in [t_0, T]$

$$Z_I(t) \lesssim \|\nabla Iu(t_0)\|_2 + g_1(t)^p Z_I(t) + N^{-(s-s_c)} Z_I(t) g_1(t)^{p-1} [g_1(t) + h_1(t)]$$

(4.3)
where \( g_1(t) \) and \( h_1(t) \) are defined by
\[
g_1(t)^p = \eta^2 \sup_{s \in [t_0, t]} E(Iu(s)) \frac{2p}{p+2} + \eta^p Z_1(t) (1-\theta)p + N^{-1-s_c} Z_1(t)^p \tag{4.4}
\]
with \( \theta = \frac{2}{3p-4} \) and
\[
h_1(t) = \eta^2 \sup_{s \in [t_0, t]} E(Iu(s)) \frac{2p}{p+2} + Z_1(t). \tag{4.5}
\]

Proof. The proof is similar to the proof of Proposition 3.1. The only difference is that we use \( \|u\|_{L^4_{t,x}} \) instead of \( \|u\|_{L^\infty_{t,x}} \) in estimates (3.9), (3.10) and (3.14). In this way, one can relax the restriction of \( p \), and to obtain estimate (4.3) for \( p \geq 2 \).

Next, we show the energy increment of \( E(Iu(t)) \).

**Proposition 4.2** (Energy increment). Let \( u(t, x) \) be an \( H^s \) solution to problem (1.1) with \( f(u) = |u|^pu \) defined on \([t_0, T] \times \mathbb{R}^2\) and satisfying
\[
\|u\|_{L^4_{t,x}(t_0, T) \times \mathbb{R}^2} \leq \eta \tag{4.6}
\]
for some small constant \( \eta \). Assume \( E(Iu(t_0)) \leq 1 \). Then for \( s \geq \max\{ \frac{p}{p+1}, \frac{1-s_c}{2} \}, p \geq 2 \) and sufficiently large \( N \), we have for any \( t \in [t_0, T] \)
\[
\left| \sup_{s \in [t_0, t]} E(Iu(s)) - E(Iu(t)) \right| \lesssim N^{-1-s_c} Z_1(t)^3 g_1(t)^{p-1} + N^{-1-s_c} Z_1(t)^2 g_1(t)^{p-1} (g_1(t) + h_1(t)) \tag{4.7}
\]
where \( g_1(t), h_1(t) \) are defined as in Proposition 4.1 and \( k_1(t) \) is defined to be
\[
k_1(t) = \eta \sup_{s \in [t_0, t]} E(Iu(s)) \frac{1}{p+2} + Z_1(t)^{p+1}.
\]

**Proof.** The proof is similar to the proof of Proposition 3.2. In fact, we use \( \|u\|_{L^4_{t,x}} \) instead of \( \|u\|_{L^\infty_{t,x}} \) in estimates (3.15), (3.16), (3.18) and (3.22). However, we estimate (3.24) in a different way as follows. By the assumption \( s > \frac{1-s_c}{2} \), we have \( \nu := 2s-s_c-1 \in (0, s) \). We obtain, by the same argument as deriving (3.13), the following estimate
\[
\left\| \left( E(Iu) \right)^{1/2}(\|u\|^{p} u) \right\|_{L^4_{t,x}} \tag{4.8}
\]
Combining the above two propositions, a standard bootstrap argument and the same argument as in the proof of Proposition 3.3, we can show that the quantity \( E(Iu)(t) \) is “almost conserved” in the following sense.

**Proposition 4.3** (Almost conservation law). Let \( u(t, x) \) be an \( H^s \) solution to problem (1.1) with \( f(u) = |u|^pu \) defined on \([t_0, T] \times \mathbb{R}^2\) and satisfying
\[
\|u\|_{L^4_{t,x}(t_0, T) \times \mathbb{R}^2} \leq \eta \tag{4.9}
\]
for some small constant $\eta$. Assume $E(Iu(t_0)) \leq 1$. Then for $s \geq \max \{\frac{1+\eta}{2}, \frac{p}{p+1}\}$, $p \geq 2$ and sufficiently large $N$, we have

$$E(Iu)(t) = E(Iu(t_0)) + O(N^{s-\eta}).$$

(4.10)

Now we turn to prove Theorem 1.2.

**The proof of Theorem 1.2** Assume $u$ is a solution to problem (1.1) with $f(u) = |u|^p u$, then so is

$$u^\lambda(t,x) = \lambda^{-\frac{1}{2}} u\left(\frac{1}{\lambda^{\frac{1}{2}}}, \frac{x}{\lambda^{\frac{1}{2}}}\right).$$

(4.11)

Choosing a sufficiently large $\lambda$ depending on $\|u_0\|_{H^s}$ and $N$ such that

$$N^{1-s}\lambda^{s-\eta}\|u_0\|_{H^s} < 1 \quad \text{and} \quad \lambda^{-\frac{2}{5}+\frac{1}{10^s}} \|u_0\|_{H^s} < 1,$$

we get

$$E(Iu^\lambda_0) = \frac{1}{2}\|\nabla Iu^\lambda_0\|_2^2 + \frac{1}{p+1}\|Iu^\lambda_0\|_{L_{T,x}^{p+1}}^p \ll 1.$$  

(4.13)

Next we claim that for any arbitrary large $T_0 > 0$, there exists an absolute constant $C$ such that

$$\|u^\lambda\|_{L_{t,x}^{\infty}([0,\lambda^2T_0] \times \mathbb{R}^2)} \leq C\lambda^s (\lambda^2T_0)^{\frac{1}{2}}.$$  

(4.14)

We prove this claim by the standard bootstrap argument. Let us define

$$\Omega_1 := \{t \in [0,\lambda^2T_0] : \|u^\lambda\|_{L_{t,x}^{\infty}([0,t] \times \mathbb{R}^2)} \leq C\lambda^s t^{\frac{1}{2}}\}.$$

We want to show $\Omega_1 = [0,\lambda^2T_0]$. Let

$$\Omega_2 := \{t \in [0,\lambda^2T_0] : \|u^\lambda\|_{L_{t,x}^{\infty}([0,t] \times \mathbb{R}^2)} \leq 2C\lambda^s t^{\frac{1}{2}}\}.$$

By the same argument as deriving Proposition 3.3, it suffices to prove that for any $T \in \Omega_2$, we have $T \in \Omega_1$. Throughout the following proof, all spacetime norms will be computed on $[0,T] \times \mathbb{R}^2$.

Using the interaction Morawetz estimate and the mass conservation, we get

$$\|u^\lambda\|_{L_{t,x}^{\infty}([0,\lambda^2T_0] \times \mathbb{R}^2)} \leq C\lambda^s (\lambda^2T_0)^{\frac{1}{2}}.$$  

(4.15)

From (3.38) and (3.39), we have the control of $\|u^\lambda(t)\|_{L_{t,x}^{\infty}H^\frac{1}{2}}$ as follows

$$\|u^\lambda(t)\|_{L_{t,x}^{\infty}H^\frac{1}{2}} \leq \|\mathcal{P}_N u^\lambda\|_{H^\frac{1}{2}} + \|\mathcal{P}_{>N} u^\lambda\|_{H^\frac{1}{2}} + \lambda^\frac{s-\eta}{2}\|u_0\|_{L_{t,x}^{\infty}H^\frac{1}{2}} + \lambda^\frac{s-\eta}{2}\|u_0\|_{L_{t,x}^{\infty}H^\frac{1}{2}}.$$  

Plugging this into (4.15), we estimate

$$\|u^\lambda\|_{L_{t,x}^{\infty}H^\frac{1}{2}} \leq \|u_0\|_{L_{t,x}^{\infty}H^\frac{1}{2}} + 2\|\mathcal{P}_N u^\lambda\|_{H^\frac{1}{2}} + \lambda^\frac{s-\eta}{2}\|u_0\|_{L_{t,x}^{\infty}H^\frac{1}{2}} + \lambda^\frac{s-\eta}{2}\|u_0\|_{L_{t,x}^{\infty}H^\frac{1}{2}}.$$  

(4.16)
In fact, let $\eta > 0$ be sufficiently small constant as in Proposition 4.3 and we divide $[0, T]$ into subintervals $I_j = [t_j, t_{j+1}]$ such that
\[ \|u_0\|_{L^4_x(I_j \times \mathbb{R}^2)} \leq \eta. \] (4.18)
Using Proposition 4.3 on each interval $I_j$, we obtain
\[ \sup_{t \in [0, T]} E(Iu^\lambda)(t) \leq E(Iu_0^\lambda) + LN^{s_0-s}. \] (4.19)
To control small energy during the iteration, we need
\[LN^{s_0-s} \approx T^N \lambda^{4s} N^{s_0-s} \ll 1.\]
\[T \ll \lambda^2 T_0\]
This property together with (4.12) and $T \ll \lambda^2 T_0$ leads to
\[ T_0^N \lambda^{s_0} \frac{1}{\lambda^{s_0}} (s-s_0) = T_0^N \frac{\lambda^{s_0}}{\lambda^{s_0}} (s-s_0) \ll 1 \] (4.20)
by choosing $N = N(\|u_0\|_{H^s}, T_0)$ large enough provided that $s$ satisfies
\[3(s-s_0)^2 - 2(1 + 6s)(1-s) > 0,\]
i.e. $s > s_1$, where $s_1$ is the positive root of the quadratic equation
\[3(s-s_0)^2 - 2(1 + 6s)(1-s) = 0.\]
This completes the bootstrap argument and hence the claim (4.14).
To estimate $\|u(t)\|_{H^s}$, by the conservation of mass, (2.6) and (4.10), we get for $t \in [0, T_0]$
\[\|u(t)\|_{H^s} \lesssim \|u_0\|_{L^2} + \|u(t)\|_{H^s} \lesssim \|u_0\|_{L^2} + \lambda^{s_0} \|\lambda^s \|_{H^s} \|u(t)\|_{H^s} \lesssim \|u_0\|_{L^2} + \lambda^{s_0} \|\lambda^s \|_{H^s} \|u_0\|_{L^2} + \lambda^{s_0} \|\lambda^s \|_{H^s} \|u_0\|_{L^2} + \lambda^{s_0} \|\lambda^s \|_{H^s} \|u_0\|_{L^2}
\leq \lambda^{s_0} \|\lambda^s \|_{H^s} (1 + \lambda^s) \leq \frac{C(\|u_0\|_{H^s}) (1 + T_0)}{\lambda^{s_0} \|\lambda^s \|_{H^s}} \leq C(\|u_0\|_{H^s})(1 + T_0) \frac{\lambda^{s_0}}{\lambda^{s_0} - 2(1 + 6s)(1-s)} \ll 1\],
where we use the relationship (4.12) and (4.20) in the last inequality. This completes the proof of Theorem 4.3.

5. Proof of Theorem 4.3

In this section, we consider the Cauchy problem for the nonlinear Schrödinger equation
\[\begin{cases}
(i\partial_t + \Delta)u = f(u) = |u|^p u + |u|^{2k} u, & (t, x) \in \mathbb{R} \times \mathbb{R}^2, \\
u(0, x) = u_0(x) \in H^s(\mathbb{R}^2).
\end{cases}\] (5.1)
If $u(t, x)$ is the solution to (5.1), then
\[\lambda^{s_0}(t, x) = \lambda^{-\frac{s_0}{2}} u\left(\frac{t}{\lambda}, \frac{x}{\lambda}\right)\]
is the solution to
\[\begin{cases}
(i\partial_t + \Delta)\lambda^{s_0} = \lambda^{-2s_0} f(\lambda^{s_0} u) + |\lambda^{s_0}|^{2k} u^{\lambda s_0} \\
u_0(0, x) = \lambda^{-\frac{s_0}{2}} u_0(\frac{x}{\lambda}),(5.2)\end{cases}\]
The energy $E(u^\lambda)$ is defined by

$$E(u^\lambda)(t) = \frac{1}{2} \int |\nabla u^\lambda(t,x)|^2 dx + \frac{1}{2(k+1)} \int |u^\lambda(t,x)|^{2(k+1)} dx + \frac{\lambda^{-2+s} + 2}{p+2} \int |u^\lambda(t,x)|^{p+2} dx.$$  

For given $u_0 \in H^s(\mathbb{R}^2)$, we have

$$\|\nabla Iu_0\|_2 \leq N^{1-s}\|u_0\|_{H^s} = N^{1-s}\lambda^{-\frac{s}{4} - s}\|u_0\|_{H^s},$$

$$\lambda^{-\frac{s}{2} + \frac{s}{4}}\|u_0\|_{p+2}^{p+2} = \lambda^{-\frac{s}{2} + \frac{s}{4} + \frac{s}{4}}\|u_0\|_{p+2}^{p+2} \leq \lambda^{-\frac{s}{2}}\|u_0\|_{p+2}^{p+2},$$

$$\|u_0\|_{2k+2} \leq \lambda^{-\frac{s}{2} + \frac{s}{4}}\|u_0\|_{2k+2} \leq \lambda^{-\frac{s}{2} + \frac{s}{4}}\|u_0\|_{H^s}.$$  

As $s > 1 - \frac{1}{\lambda}$, choosing $\lambda$ sufficiently large depending on $\|u_0\|_{H^s}$ and $N$ such that

$$N^{1-s}\lambda^{-\frac{s}{4} - s}\|u_0\|_{H^s} \ll 1 \text{ and } \lambda^{-\frac{s}{2} + \frac{s}{4}}\|u_0\|_{H^s} \ll 1,$$

we obtain

$$E(Iu_0) \leq 1.$$  

### 5.1. Almost conservation law.

Let us define $Z_I(t)$ by

$$Z_I(t) := \|Iu\|_{Z_I} = \sup_{(q,r) \in \mathbb{A}_0} \left( \sum_{|a| \geq 1} \|\nabla P_N Iu(t)\|_{L^p_t L^q_x([t_0,t] \times \mathbb{R}^2)} \right)^\frac{1}{p}.$$  

Moreover, we denote

$$s_c^{(1)}(1) = 1 - \frac{2}{p}, \quad s_c^{(2)} = 1 - \frac{2}{N}, \quad s_c^{(1)} < s_c^{(2)}.$$  

### Proposition 5.1.

Let $u(t,x)$ be an $H^s$ solution to problem [5.2] defined on $[t_0,T] \times \mathbb{R}^2$ and satisfying

$$\|u\|_{L^p_t L^q_x([t_0,T] \times \mathbb{R}^2)} \leq \eta$$  

for some small constant $\eta$. Assume $E(Iu(t_0)) \leq 1$. Then for sufficiently large $N$,  

$$s > \max \left\{ s_c^{(1)}, \frac{1 + s_c^{(1)}}{2}, s_c^{(2)} \right\} = \max \left\{ \frac{1 + s_c^{(1)}}{2}, s_c^{(2)} \right\}, \quad 2k > p > \frac{5}{2},$$

and $k$ is an integer number larger than one,

$$Z_I(t) \lesssim \|\nabla Iu_0\|_2 + \lambda^{-\frac{s}{2} + \frac{s}{4}} \left[ \tilde{g}(t)^p Z_I(t) + N^{-s-s_k} Z_I(t) \tilde{g}(t)^{p-1} (\tilde{g}(t) + \tilde{h}(t)) \right] + g_k(t)Z_I(t).$$  

where $\tilde{g}(t), \tilde{h}(t)$ and $g_k(t)$ are defined by

$$\tilde{g}(t) = \eta^p \lambda^2(2 - \frac{s}{4}) \frac{1 + s_c^{(1)}}{2} \sup_{s \in [t_0, t]} E(Iu(s))^{\frac{1 - s_c^{(1)} + 1}{p + 2}} + \eta^2 Z_I(t) \lambda^{1 - \theta_2} P \eta^p Z_I(t) \lambda^{1 - \theta_2} + N^{-s - s_k} Z_I(t) \tilde{g}(t)^{p-1} (\tilde{g}(t) + \tilde{h}(t)),$$

$$\tilde{h}(t) = \eta^{2s} \lambda^{2 - \frac{s}{4}} \frac{1 + s_c^{(1)}}{2} \sup_{s \in [t_0, t]} E(Iu(s))^{\frac{1 - s_c^{(1)} + 1}{p + 2}} + Z_I(t),$$

$$g_k(t) = \eta^{2k} \sup_{s \in [t_0, t]} E(Iu(s))^{\frac{1 - s_c^{(1)} + 1}{p + 2}} + \eta^{2k} \lambda^{2 - \frac{s}{4}} \frac{1 + s_c^{(1)}}{2} \sup_{s \in [t_0, t]} E(Iu(s))^{\frac{1 - s_c^{(1)} + 1}{p + 2}} + N^{-2k - (1-s_k)} Z_I(t) \lambda^{2k} Z_I(t) \lambda^{1 - \theta_2} + N^{-2k - (1-s_k)}.$$

with $\theta_1, \theta_2 \in (0,1)$ defined as in Proposition 3.1.

### Proof.

Using the Strichartz estimate [2.3], we get from [5.2]

$$Z_I(t) \lesssim \|\nabla Iu_0\|_2 + \|\nabla I(u)\|_{L^{t,x}_p}^{\frac{1}{p}} \lesssim \|\nabla Iu_0\|_2 + \lambda^{-\frac{s}{2} + \frac{s}{4}} \|\nabla I(u\|_{L^{t,x}_p}^{\frac{1}{p}} + \|\nabla I(u^{2k}u)\|_{L^{t,x}_p}^{\frac{1}{p}} + \|\nabla I(u^{2k}u)\|_{L^{t,x}_p}^{\frac{1}{p}}.$$  

(5.8)
Proof. Since

\[
\|u_{\leq 1}\|_{L^p_t L^q_x} \lesssim \|u_{\leq 1}\|_{L^p_t L^q_x} \lesssim \eta \|u_{\leq 1}\|_{L^p_t L^q_x} \lesssim \eta \|u_{\leq 1}\|_{L^p_t L^q_x},
\]

we obtain in the same way as deriving (3.8) and (3.13), the inequality

\[
\|\nabla I(u^p u)\|_{L^p_{t,x}} \lesssim \tilde{g}(t)^p Z_I(t) + N^{-(s-s_0)} Z_I(t) \tilde{g}(t)^{p-1} (\tilde{g}(t) + \tilde{h}(t)),
\]

where \(\theta_1 = \frac{\tilde{g}}{\tilde{g}^p}\) with \(p \geq \frac{\tilde{g}}{\tilde{g}^p}\).

On the other hand, using the fact that \(\nabla I\) acts as a derivative, we obtain

\[
\|\nabla I(|u|^{2k} u)\|_{L^p_{t,x}} \lesssim \|u|^{2k}\|_{L^p_{t,x}} \|
abla I u\|_{L^p_{t,x}}, \quad \forall \ t \in [t_0, T].
\]

Using estimate (3.12) with \(p = 2k\), we deduce

\[
\|u\|_{L^p_{t,x}} \lesssim \eta^{2k\theta_1} \sup_{s \in [t_0, t]} E(I(u(s)))^{(1-\theta_1)k} + \eta^{2k\theta_2} Z_I(t)^{2k(1-\theta_2)} + N^{-2} Z_I(t)^{2k}.
\]

This together with (5.8), (5.10) and (5.11) yields (5.7).

Proposition 5.2 (Energy increment). Let \(u(t,x)\) be an \(H^s\) solution to problem (5.2) defined on \([t_0, T] \times \mathbb{R}^2\) and satisfying

\[
\|u\|_{L^p_{t,x}(\{0,T\}\times\mathbb{R}^2)} \leq \eta
\]

for some small constant \(\eta\). Assume \(E(I(u(t_0))) \leq 1\). Then for

\[
s \geq \frac{2k}{2k+1}, \quad 2k > p \geq \frac{11}{8}, \quad 2 \leq k \in \mathbb{N}
\]

and sufficiently large \(N\), we have

\[
\left| \sup_{s \in [t_0, t]} E(I(u(s)) - E(I(u(t_0))) \leq h_1(t) + h_2(t) + h_3(t) + h_4(t),
\]

where the quantities \(h_j(t)\) (\(j = 1, 2, 3, 4\)) are defined below in (5.20), (5.21), (5.23), (5.24).

Proof. Since

\[
i u_t + \Delta u = If(u) = \lambda^{-2+\frac{\tilde{g}}{\tilde{g}^p}} I(|u|^p u) + I(|u|^{2k} u),
\]
by a simple computation, we obtain
\[
E(Iu(t)) - E(Iu(t_0)) = \int_{t_0}^t \frac{\partial}{\partial s} E(Iu(s)) ds
\]
\[
= \Im \int_{t_0}^t \int_{R^d} \Delta Iu \left[ |Iu|^{2k} Iu - |Iu|^{2k} \right] dx ds
\]
\[
- \lambda^{-2+\beta} \Im \int_{t_0}^t \int_{R^d} \nabla Iu \cdot \nabla \left[ |Iu|^p Iu - |Iu|^p u \right] dx ds
\]
\[
- \lambda^{-2+\beta} \Im \int_{t_0}^t \int_{R^d} \left[ |Iu|^p Iu - |Iu|^p u \right] dx ds
\]
\[
\lambda^{-2+\beta} \Im \int_{t_0}^t \int_{R^d} \frac{\partial}{\partial s} E(Iu(s)) ds
\]
Recalling the result in [8, Proposition 5.2], we have for \( s > \frac{2(k-1)}{2k+1} \)
\[
\lesssim N^{-1+} \left( Z_1(t)^{2k+2} + \eta^{2k+2} Z_1(t)^2 \sup_{s \in [t_0,t]} E(Iu(s)) \frac{(1-\delta_{0k})}{s+1} \right)
\]
\[
+ \sum_{J=3}^{2k+2} \eta^{(2k+2-J)\delta J} Z_1(t)^J \sup_{s \in [t_0,t]} E(Iu(s)) \frac{(1-\delta_{0k})}{s+1} \)
\]
\[
+ N^{-1+} \left( Z_1(t)^{2k+2} + \eta^{2k+2} Z_1(t) \sup_{s \in [t_0,t]} E(Iu(s)) \frac{(1-\delta_{0k})}{s+1} \right)
\]
\[
\times \left( Z_1(t)^{2k+2} + \eta^{2k+2} Z_1(t) \sup_{s \in [t_0,t]} E(Iu(s)) \frac{(1-\delta_{0k})}{s+1} \right)
\]
\[
+ N^{-1+} \sum_{J=3}^{2k+2} \eta^{(2k+2-J)\delta J} Z_1(t)^J \sup_{s \in [t_0,t]} E(Iu(s)) \frac{(1-\delta_{0k})}{s+1} \)
\]
\[
\times \left( Z_1(t)^{2k+2} + \eta^{2k+2} Z_1(t) \sup_{s \in [t_0,t]} E(Iu(s)) \frac{(1-\delta_{0k})}{s+1} \right)
\]
\[
=: h_1(t),
\]
where \( \delta_{0k}, \delta_{01}, \delta_7 \in (0,1) \) are defined by
\[
\delta_{0k} = \frac{\delta}{4k}, \quad \delta_{01} = \frac{5}{4(2k+1)}, \quad \delta_7 = \frac{6}{3(2k+1)}.
\]
Here, we adopt the interaction Morawetz norm \( L_t^5 L^8_x \) instead of \( L_t^4 L^8_x \)-norm as used in [8]. There is only one difference appearing in the power of \( \eta \) and \( E(Iu) \).

While, by Proposition 3.2, we have for \( s \geq \frac{1}{p+1} \) and \( p \geq \frac{1}{2} \)
\[
\lesssim \lambda^{-2+\beta} \left( N^{-1+} Z_1(t) \tilde{g}(t)^{p-1} + N^{-1} Z_1(t) \tilde{g}(t)^{p-1} \tilde{h}(t) \right)
\]
\[
+ \lambda^{-2+\beta} \tilde{h}(t) \left( N^{-1} \tilde{g}(t)^p \tilde{Z}_1(t) + \eta N^{-1} \tilde{Z}_1(t) \tilde{m}(t) \right) =: h_2(t),
\]
where \( q = \frac{5p}{2} \), and \( \tilde{k}(t), \tilde{m}(t) \) are defined by
\[
\begin{aligned}
\tilde{k}(t) &= q^{\theta(p+1)} (e^{-\tilde{C}})^{\frac{(1-\theta)(p+1)}{p+2}} \sup_{s \in [t_0, t]} E(Iu(s))^{\frac{(1-\theta)(p+1)}{p+2}} + Z_I(t)^{p+1}, \quad \theta_3 = \frac{5}{3(p+1)} \\
\tilde{m}(t) &= q^{1+\theta} \tilde{g}(t)^{(1-\theta)(p+1)} (1-\theta) Iu(t) + Z_I(t), \quad \theta_4 = \frac{1}{4p-10}.
\end{aligned}
\]

- **The estimate of (5.18):** By the same argument as leading to (5.14), we have for
\[
|5.18| \lesssim \lambda^{-2+\frac{p}{2N} - 1} \sup_N \| P_N I |u|^p u \|_{L^4_{t,x}} \left\{ Z_I(t)^{2k+2} + q^{2k \theta_3} Z_I(t)^2 \sup_{s \in [t_0, t]} E(Iu(s))^{\frac{(1-\theta)(p+1)}{p+2}} \right. \\
+ \sum_{J=3}^{2k+2} q^{2k+2-J} \theta_3 Z_I(t)^J \sup_{s \in [t_0, t]} E(Iu(s))^{\frac{(1-\theta)(2k+2-J)}{2(k+1)}} \bigg\}, \quad s > \frac{2(k-1)}{2k-1}. \tag{5.22}
\]

To estimate \( \| P_N I |u|^p u \|_{L^4_{t,x}} \), we obtain by (3.21)
\[
\| P_N I |u|^p u \|_{L^4_{t,x}} \lesssim \| |u|^{p+1} \|_{L^4_{t,x}} \left\{ \lambda^{2-\frac{p}{2N}} (e^{-\tilde{C}})^{\frac{(1-\theta)(p+1)}{p+2}} \sup_{s \in [t_0, t]} E(Iu(s))^{\frac{(1-\theta)(p+1)}{p+2}} + Z_I(t)^{p+1}, \right.
\]
where \( \theta_3 = \frac{5}{3(p+1)} \) and we need the restriction \( s \geq \frac{p}{p+1} \) in the estimate of the high frequency part by means of (5.8) with \( \sigma = \frac{p}{p+1} \). Plugging this into (5.22) gives
\[
|5.18| \lesssim \lambda^{-2+\frac{p}{2N} - 1} \left\{ \lambda^{2-\frac{p}{2N}} (e^{-\tilde{C}})^{\frac{(1-\theta)(p+1)}{p+2}} \sup_{s \in [t_0, t]} E(Iu(s))^{\frac{(1-\theta)(p+1)}{p+2}} + Z_I(t)^{p+1} \right. \\
\times \left\{ \sum_{J=3}^{2k+2} q^{2k+2-J} \theta_3 Z_I(t)^J \sup_{s \in [t_0, t]} E(Iu(s))^{\frac{(1-\theta)(2k+2-J)}{2(k+1)}} \bigg\} \\
=: h_3(t). \tag{5.23}
\]

- **The estimate of (5.19):** By the same argument as deducing (5.20), we get
\[
|5.19| \lesssim \lambda^{-2+\frac{p}{2N}} \| |u|^{2k+1 + \bar{\theta}} \|_{L^4_{t,x} L^{2k+1 + \bar{\theta}}_{t,x}} \left\{ \| |u| |u|^p - |u|^p \|_{L^4_{t,x} L^{p+1}_{t,x}} + \| |u| |u|^p - I(|u|^p u) \|_{L^4_{t,x} L^{p+1}_{t,x}} \right\} \\
\lesssim \lambda^{-2+\frac{p}{2N}} \left\{ q^{2k+1+\bar{\theta}} \sup_{s \in [t_0, t]} E(Iu(s))^{\frac{(1-\theta)(2k+1)+1}{2k+1}} + Z_I(t)^{2k+1} \right\} \\
\times \left\{ N^{-1} \tilde{g}(t)^p Z_I(t) + N^{-1-s} \tilde{g}(t)^{1+s} \tilde{m}(t) \right\} \\
\lesssim \lambda h_4(t). \tag{5.24}
\]

where \( q = \frac{5p}{2} \), \( \tilde{g}(t) \) is defined as in Proposition 5.1. We need the restriction \( s \geq \frac{2k}{2k+1} \) in the estimate of the high frequency part by means of (5.8) with \( \sigma = \frac{2k}{2k+1} \).

Note that \( \frac{2k}{2k+1} > \max \left\{ \frac{2k-1}{2k+1}, \frac{p}{p+1} \right\} \) and collecting (5.20)-(5.24), we obtain (5.13). Therefore, we conclude the proof of this proposition. \( \square \)
Combining the above two propositions, a standard bootstrap argument and arguing as in the proof of Proposition 5.3, we can easily show that the quantity $E(Iu)(t)$ is “almost conserved” by using the condition

$$s_c^{(2)} < \min \left\{ \frac{1+s_c^{(1)}}{2}, \frac{2k}{2k+1} \right\}.$$  

**Proposition 5.3** (Almost conservation law). Let $u(t, x)$ be an $H^s$ solution to problem 5.2 with defined on $[0, T] \times \mathbb{R}^2$ and satisfying

$$\|u\|_{L^1_t,\mathbb{R}^2(\mathbb{R} \times \mathbb{R}^2)} \leq \eta$$  

for some small constant $\eta$. Assume $E(Iu_0) \leq 1$. Then for

$$s \geq \max \left\{ \frac{1+s_c^{(1)}}{2}, \frac{2k}{2k+1} \right\}, \quad 2k > \frac{1}{4}, \quad 2 \leq k \in \mathbb{N}$$

and sufficiently large $N$, we have

$$E(Iu)(t) = E(Iu_0) + O\left( \max \left\{ N^{-1}, \lambda^{-2}(2-t)(1-\frac{(1-\theta)\eta}{\eta+k})N^{-s} \right\} \right),$$  

where $\theta_1 = \frac{5}{2p}$.

**Proof.** By the same way as deducing Proposition 4.3, we derive that the contributions of $h_j(t) (j = 1, 2, 3, 4)$ to the difference $E(Iu(t)) - E(Iu(t))$ are

$$N^{-1}, \lambda^{-2}(2-t)(1-\frac{(1-\theta)\eta}{\eta+k})N^{-s}, \lambda^{-2}(2-t)N^{-1},$$

$$\lambda^{-2}(2-t)N^{-s} \lambda(2-t)(1-\theta_1)$$

respectively. This fact gives the formula (5.26). \qed

5.2. Global well-posedness and scattering. By an argument as similar to that in Section 3, we can reduce the proof of Theorem 4.3 to the following proposition.

**Proposition 5.4.** Suppose $u(t, x)$ is a global solution to problem (1.1) with $f(u) = |u|^p u + |u|^{2k} u$ and $u_0 \in C_0^\infty(\mathbb{R}^2)$. Then for

$$2k > \frac{1}{4}, \quad 1 < k \in \mathbb{N},$$

and

$$s \in (\tilde{s}_3, 1), \quad \tilde{s}_3 := \max \left\{ \frac{1+s_c^{(1)}}{2}, \frac{2k}{2k+1}, \frac{5s_c^{(2)}}{4s_c^{(2)}+1}, \quad s_3 \right\}$$

with $s_3$ being the positive root of the quadratic equation

$$s^2 - (s_c^{(1)} + s_c^{(2)} - \alpha)s - \alpha = 0, \quad \alpha = 4s_c^{(2)} - \frac{9(2-p)}{2(p+2)},$$

we have

$$\|u\|_{L^1_t,\mathbb{R}^2(\mathbb{R} \times \mathbb{R}^2)} \leq C\left( \|u_0\|_{H^s(\mathbb{R}^2)} \right),$$  

$$\sup_{t \in \mathbb{R}} \|u(t)\|_{H^s(\mathbb{R}^2)} \leq C\left( \|u_0\|_{H^s(\mathbb{R}^2)} \right).$$

**Proof.** By the same argument as in the proof of Proposition 5.3 and the scaling transform, we claim that

$$\|u^\lambda\|_{L^1_t,\mathbb{R}^2(\mathbb{R} \times \mathbb{R}^2)} \leq C\lambda^k s_c^{(2)}. $$

Indeed, we define

$$\Omega_1 := \left\{ t \in [0, \infty) : \|u^\lambda\|_{L^1_t,\mathbb{R}^2([0,t]\times\mathbb{R}^2)} \leq C\lambda^k s_c^{(2)} \right\}.$$  

We want to show $\Omega_1 = [0, \infty)$. Let

$$\Omega_2 := \left\{ t \in [0, \infty) : \|u^\lambda\|_{L^1_t,\mathbb{R}^2([0,t]\times\mathbb{R}^2)} \leq 2C\lambda^k s_c^{(2)} \right\}.$$
Then, it suffices to show $\Omega_2 \subset \Omega_1$ by the standard bootstrap argument. In the same way as deriving (5.30), it is sufficient to prove
\[
\sup_{\eta \in [0, T]} \|Iu^\lambda\|_{H^1} \leq 1, \quad T \in \Omega_2.
\] (5.30)
In fact, let $\eta > 0$ be a sufficiently small constant as in Proposition 5.3 and we divide $[0, T]$ into subintervals $I_j = [t_j, t_{j+1}]$ such that
\[
\|u^\lambda\|_{L^\infty_x(I_j \times \mathbb{R}^2)} \leq \eta.
\] (5.32)
Using Proposition 5.3 on each interval $I_j$, we obtain
\[
\sup_{t \in [0, T]} E(Iu^\lambda)(t) \leq E(Iu^\lambda_0) + \mathcal{O}\left( \max \left\{ N^{-1+\epsilon}, \lambda^{-(2-\frac{9}{4})\left(1-\frac{12-6p}{p+2}\right)}N^{-\left(s-s^{(1)}\right)} \right\} \right).
\] (5.33)
To maintain a small energy during the iteration, we need the estimate
\[
\mathcal{O}\left( \max \left\{ N^{-1+\epsilon}, \lambda^{-(2-\frac{9}{4})\left(1-\frac{12-6p}{p+2}\right)}N^{-\left(s-s^{(1)}\right)} \right\} \right) \lesssim 1,
\]
which together with (5.3) leads to
\[
\lambda^{4\epsilon(2)} N^{-1+\epsilon} \simeq N^{4\epsilon(2)\frac{1+\epsilon}{s-s^{(1)}}} N^{-1+\epsilon} \simeq N^{\frac{3p-4-\frac{1}{p} - \frac{12-6p}{p+2}}{p(s+1)-1}} \ll 1
\]
and
\[
\lambda^{4\epsilon(2)} \lambda^{-(2-\frac{9}{4})\left(1-\frac{12-6p}{p+2}\right)}N^{-\left(s-s^{(1)}\right)} \simeq N^{\frac{1-s}{s-s^{(1)}}} \ll 1
\]
with
\[
\alpha = 4\epsilon(2) - (2-\frac{9}{4})(1-\frac{12-6p}{p+2}) = 4\epsilon(2) - \frac{9(2-\frac{9}{4})}{2(p+2)}.
\]
They may be ensured by choosing $N = N(\|u_0\|_{H^s})$ large enough provided
\[
s > \max\left\{ \frac{5\epsilon(2)}{4\epsilon(2)+1}, s_3 \right\},
\]
where $s_3$ is the positive root of the quadratic equation
\[
s^2 - (s^{(1)} + s^{(2)} - \alpha)s - \alpha = 0.
\]
This completes the bootstrap argument, and hence Proposition 5.3 follows. Therefore, we conclude Theorem 1.3.

\section*{Appendix}

In this Appendix, we state the result in the one dimension. In fact, the proof is the same as in the case dimension two. We utilize the following classical interaction Morawetz estimates in [30, 46]
\[
\|u\|_{L^4_{xy}(I \times \mathbb{R})} \lesssim \|u\|_{L^\infty_t(\{0\} \cup L^2_{x,y}(\mathbb{R}))} \|u_0\|_{L^2_x}^{\frac{3}{2}},
\] (A.1)
and the improved interaction Morawetz estimates in [7]
\[
\int_0^T \int \left|u(t,x)\right|^6 dx dt \lesssim T^{\frac{1}{2}} \|u_0\|_{L^2_x}^3 \|u\|_{L^\infty_{t,x}((0,T), L^2_{x,y})}^2 + T^{\frac{1}{4}} \|u_0\|_{L^2_x}^6,
\] (A.2)
instead of (1.17) and (1.16).
Define
\[ s_0 := \max \left\{ \frac{1+s_c}{2}, \frac{p}{2(\rho+1)} \right\}, \quad s_1 = \frac{1}{2} - \frac{2}{p}, \]
\[ \tilde{s}_0 := \max \left\{ \frac{1+s_c}{2}, \frac{dp}{2(\rho+1)} \right\}, \quad \tilde{s}_1, \]
where \( s_1 \) is the positive root of the quadratic equation
\[ s^2 + 5s_c s + s_c^2 - 7s_c = 0, \]
and \( \tilde{s}_1 \) is the positive root of the quadratic equation
\[ 3(s - s_c)^2 - 2(1 + 9s_c)(1 - s) = 0. \]

**Theorem A.1.** (i) Assume that \( u_0 \in H^s(\mathbb{R}) \) with \( s \in (s_0, 1) \) and \( p \geq \frac{4}{3} \). Then the solution \( u \) to \( iu_t + \Delta u = |u|^p u \) is global and scatters.
(ii) Assume that \( u_0 \in H^s(\mathbb{R}) \) with \( s \in (\tilde{s}_0, 1) \) and \( p \geq 4 \). Then the solution \( u \) to \( iu_t + \Delta u = |u|^p u \) is global. Furthermore, for any \( T > 0 \),
\[ \sup_{t \in [0, T]} \|u(t)\|_{H^s(\mathbb{R})} \leq C \left( (\|u_0\|_{H^s(\mathbb{R})}) (1 + T)^{\frac{\tilde{s}_c - s}{2(1 + 9s_c)(1 - s)}} \right)^+. \]
(iii) Assume that \( u_0 \in H^s(\mathbb{R}) \) with \( s \in \left( \max \left\{ \frac{1+s_c(2)}{2}, \frac{p_2}{2(\rho+1)} \right\}, s_2 \right) \), \( s_c(j) = \frac{1}{2} - \frac{2}{p^j} \), \( j = 1, 2, \frac{17}{3} \leq p_1 < p_2 \) and \( s_2 \) is the positive root of the quadratic equation
\[ s^2 + 5s_c^{(2)} s + (s_c^{(2)})^2 - 7s_c^{(2)} = 0. \]
Then the solution \( u \) to \( iu_t + \Delta u = |u|^{p_1} u + |u|^{p_2} u \) is global and scatters.
