We observe both dc voltage rectification and frequency conversion that occur when a reference microwave current is injected to a MgO based magnetic tunnel junction (MTJ). The rectification that is spin-transfer torque dependent is observed when the frequency of the input microwave current coincides with the resonance frequency of the magnetization of the active layer. In addition, we demonstrate that frequency conversion is the result of amplitude modulation between the reference signal and the resistance of the MTJ that is fluctuating at the resonance frequency of the magnetization of the active layer. © 2009 The Japan Society of Applied Physics

MgO-based magnetic tunnel junctions (MTJs) are extensively studied because of their implementation in hard disk reading heads or as bit cells in magnetic random access memories (MRAM).¹ Recent improvements in their fabrication process resulting in low resistive insulating barrier has made possible the observation of spin-transfer torque phenomena.¹–³ The transfer of spin angular momentum from a spin-polarized current to a ferromagnet enables to manipulate magnetization without magnetic field.⁴–⁵ This effect can be used for example to induce steady magnetization precessions by injection of a dc current. These magnetic dynamical regimes are converted into a microwave electrical signal through the magneto-resistive effect.⁶–¹¹ Spin transfer nano-oscillators (STNOs) offer high potentialities for a new generation of nanoscale high frequency synthesizer for telecommunication applications. Standard microwave features such as the frequency modulation of the STNO output signal has also been evidenced when a low frequency ac current is added to the dc current.¹² Moreover, for an excitation frequency much closer to the natural STNO one, frequency locking occurs.¹³,¹⁴ Analytical calculation of such phenomena has been extended to the description of the phase locking in arrays of coupled STNOs.¹⁵ In addition, the injection of a pure high frequency signal at the resonance frequency $f_{\text{FMR}}$ of the active magnetic layer is known to generate a dc rectified voltage¹⁶–¹⁸ and a microwave signal at $2f_{\text{FMR}}$¹⁹ across the device.

In this work, we demonstrate the frequency conversion of an input microwave signal, with an arbitrary frequency $f_{\text{rf}}$, obtained by the mixing with the ferromagnetic resonance frequency $f_{\text{FMR}}$ of the free magnetic layer in a MgO-based MTJ, not biased with dc current. When the input signal frequency $f_{\text{rf}}$ coincides with $f_{\text{FMR}}$, a dc rectified voltage is measured across the device. For $f_{\text{rf}} \neq f_{\text{FMR}}$, microwave spectra are characterized by two modulation peaks at respectively $|f_{\text{rf}} - f_{\text{FMR}}|$ and $f_{\text{rf}} + f_{\text{FMR}}$. This proves that, potentially, magneto-resistive devices could be used as a powerless nanoscale microwave frequency mixer.

The samples used are magnetic tunnel junctions composed of PtMn (15)/Co$_{90}$Fe$_{20}$ (2.5)/Ru (0.85)/Co$_{90}$Fe$_{20}$B$_{20}$ (3)/MgO (1.075)/Co$_{90}$Fe$_{20}$B$_{20}$ (2) (nm) patterned into an elliptical shape of dimension $170 \times 70 \text{nm}^2$.²⁰ The tunnel magneto-resistance ratio (TMR) is 100% and the RA product is 0.85 Ωμm² for the parallel (P) magnetization configuration at room temperature. An in-plane magnetic field $H$ (between 150 to 500 Oe) is applied along the hard axis of the ellipse in order to increase the amplitude of the measured microwave signals.

A microwave current delivered by an external source is injected into the sample through the capacitive branch of a bias tee via a 2–4 GHz circulator as shown in the inset of Fig. 1(a). The dc voltage across the MTJ is measured at the inductive output of the bias tee. The microwave part of the output signal is recorded onto a spectrum analyzer connected to the third circulator port. The frequency of the microwave input signal $f_{\text{rf}}$ is swept from 100 MHz up to 6 GHz. The rectified dc and microwave output voltages have been recorded for four values of the input power: $P = -25$, $-20$, $-15$, and $-10$ dBm. The actual amplitude of the microwave current passing through the sample depends on the frequency because of the mismatch impedance and the use of the circulator. We estimate that the maximum injected current obtained for $P = -10$ dBm is about 0.4 mA at $f_{\text{rf}} = 3$ GHz.

In Fig. 1(a), we show a typical rectified dc voltage measured as function of $f_{\text{rf}}$ for $H = 210$ Oe and $P = -15$ dBm. An asymmetric negative peak with a minimum of rectification $V_{\text{min}} = -1.1$ mV is observed at 2.32 GHz. This peak corresponds to the electrical response of the spin-transfer induced resonant excitation of the magnetization of the free layer.¹⁶,¹⁷ The calculation of the rectified dc voltage as function of $f_{\text{rf}}$ can be obtained from the Landau–Lifshitz–Gilbert including spin transfer torques. It corresponds to the dc component of $I_{\text{d}} \cos(2\pi f_{\text{rf}} / f_{\text{FMR}}) \Delta R(I_{\text{d}}, f_{\text{rf}})$, where $\Delta R(I_{\text{d}}, f_{\text{rf}})$ is the frequency dependent resistance variation when the magnetic moment of the free layer is harmonically excited at its resonance frequency by a microwave current. As $\Delta R(I_{\text{d}}, f_{\text{rf}})$ is proportional to $I_{\text{d}}$, it comes out that the rectified voltage goes as $I_{\text{d}}^2$. We confirm this behavior by measuring a linear variation of the measured minimum rectified voltage $V_{\text{min}}$ as a function of $P$ [see inset of Fig. 1(b)]. Moreover, the lineshape of $V_{\text{dc}}(f_{\text{rf}})$ is composed of symmetric and antisymmetric lorentzian attributed respectively to the Slonczewski-torque and the field-like torque [see plain line in Fig. 1(a)]. By fitting the experimental lineshape of $V_{\text{dc}}(f_{\text{rf}})$ at different magnetic fields, we extract the dependence of the resonance frequency $f_{\text{FMR}}$ with

¹E-mail address: vincent.cros@thalesgroup.com
function of the input microwave frequency. Inset: Dependence of the amplitude of the rectified dc voltage as the resonance frequency with the magnetic field. The red line is a fit using the Kittel formula [see Fig. 1(b)].

For such geometry, the resonance frequency is given by

\[ f_{\text{FMR}} = \left( \frac{\gamma}{2\pi} \right) \sqrt{(H - H_{\text{an}})(H + 4\pi M_s)}, \]

where \( \gamma = 28 \times 10^{-4} \text{GHz/Oe} \) is the gyromagnetic ratio, \( H_{\text{an}} \) is the uniaxial anisotropy field and \( 4\pi M_s \) is the effective magnetization. The best fitting parameters are \( H_{\text{an}} = 137 \text{Oe} \) and \( 4\pi M_s = 9900 \text{Oe} \). Thus, from the spin-diode measurements, we have access to the resonance frequency of the active layer at any temperature.

We now turn to the description of the microwave output signals. In Fig. 2(a), we show the power spectral density (PSD) obtained at \( H = 250 \text{Oe} \) with \( f_{\text{rf}} = 0.6 \text{GHz} \) and \( P = -10 \text{dBm} \) (no dc current is applied). Two peaks at 2.34 and 3.54 GHz are detected at frequencies corresponding respectively to \( f_{\text{FMR}} - f_{\text{rf}} \) and \( f_{\text{FMR}} + f_{\text{rf}} \) (the position of the resonance frequency \( f_{\text{FMR}} = 2.94 \text{GHz} \) is indicated by the vertical dashed line). In Fig. 2(b), we present the evolution of the peak positions and amplitudes (in color scale) with \( f_{\text{rf}} \). Note that on this plot, the peak corresponding to the signal of the source at \( f_{\text{rf}} \) has been subtracted. As \( f_{\text{rf}} \) increases up to \( f_{\text{FMR}} \), the two peaks follow their respective branches \( f_{\text{FMR}} - f_{\text{rf}} \) and \( f_{\text{FMR}} + f_{\text{rf}} \). Above \( f_{\text{FMR}} \), the lowest frequency branch follows \( f_{\text{rf}} - f_{\text{FMR}} \). These peaks are characteristic of the modulation between two signals with different frequencies.

In our experiment, no dc current is applied and the resonance frequency \( f_{\text{FMR}} \) is weakly dependent on the rf current over the range ±0.4 mA, thus frequency modulation is negligible in this case. Therefore the observed modulation phenomena is associated to amplitude modulation (AM). Indeed, if we assume that the magnetization is fluctuating at its resonance frequency, the MTJ resistance has an oscillating component at \( f_{\text{FMR}} \): \( R(t, T) = R_0 + \Delta R(T) \cos(2\pi f_{\text{FMR}} t) \), where \( R_0 \) is the nominal resistance. The amplitude of the resistance variation \( \Delta R(T) \), related to the amplitude of the magnetization fluctuations, is only determined by the temperature \( T \). When injecting a microwave signal at the frequency \( f_{\text{rf}} \), the resulting output voltage is:
that corresponds to an equation of amplitude modulation. The last two terms in eq. (1) indicate that the output voltage has a component at \( f_\text{rf} - f_\text{FMR} \) and another one at \( f_\text{FMR} + f_\text{FMR} \). This difference is due to the fact that the resistance variation associated to the magnetization fluctuations should not depend on \( I_\text{rf} \). In the inset of Fig. 2(a), we display the evolution of the \( f_\text{FMR} - f_\text{FMR} \)-modulated peak PSD (\( \propto V^2_\text{out} \)) with the source power (\( \propto I_\text{rf}^2 \)), obtained for \( H = 250 \text{ Oe} \), and \( f_\text{FMR} = 0.6 \text{ GHz} \). We observe a linear response of the output voltage with the microwave current, confirming that, in this regime, the amplitude of the magnetization motion is independent on \( I_\text{rf} \).

Notice that in the case of AM, \( f_\text{FMR} \) and \( f_\text{FMR} + f_\text{FMR} \) peaks should have the same amplitude that we do not observe experimentally. Actually, because of impedance mismatch effects, both \( I_\text{rf} \) and the PSD are frequency dependent leading to different amplitudes for the \( f_\text{FMR} \) and \( f_\text{FMR} + f_\text{FMR} \) peaks. Besides, if nonlinear effects are strong enough to make \( f_\text{FMR} \) be dependent on the applied current, amplitude modulation but also frequency modulation will occur.\(^{\text{12}\text{}}\)

To summarize, we have measured simultaneously the dc and microwave output voltages across a MgO-based MTJ while injecting only a microwave current. For an injection frequency equal to the resonance frequency of the magnetization of the active layer, a rectified dc voltage occurs through the TMR effect at the MTJ. For this resonant excitation case, the amplitude of the magnetization motion, then the resistance variation, is proportional to the microwave current amplitude, leading to a rectified voltage proportional to \( I_\text{rf}^2 \). For any other frequency, the microwave output spectra show modulated peaks between the resonance frequency and the input frequency. As, in this case, the magnetization is at the thermal equilibrium, its motion amplitude, and then the resistance variation, only depends on the temperature, and not on the microwave current, leading to an microwave output voltage proportional only to \( I_\text{rf} \).

These results demonstrate that magneto-resistive devices might be used as nanosized microwave mixer operating at high frequencies.
