Out of equilibrium correlation functions of quantum anisotropic XY models: one-particle excitations.

Luigi Amico and Andreas Osterloh
NEST-INFM & Dipartimento di Metodologie Fisiche e Chimiche (DMFCI), viale A. Doria 6, 95125 Catania, ITALY

We calculate exactly matrix elements between states that are not eigenstates of the quantum XY model for general anisotropy. Such quantities therefore describe non equilibrium properties of the system; the Hamiltonian does not contain any time dependence. These matrix elements are expressed as a sum of Pfaffians. For single particle excitations on the ground state the Pfaffians in the sum simplify to determinants.

I. INTRODUCTION

Spin systems are paradigmatic models for describing many phenomena in contemporary physics [1]. Often their main properties can be captured qualitatively, resorting on approximated techniques. However, in many cases more refined approaches are required to obtain reliable results. A prime example are systems near or at a phase transition, where quantum fluctuations inhibit many standard routes from working (as e.g mean-field theory but also perturbation theory). At the critical point, in change, the system can remarkably be simplified by a then present large class of symmetries. Conformal field theory employs systematically this important property of the system at criticality and the corresponding dynamics can be integrated exactly in 1+1 dimensions. Much more difficulties arise when the system is far from either, criticality and accessibility to mean-field or perturbation theory. Fortunately there are many non-trivial systems for which the symmetry is large enough to allow the dynamics being integrated exactly even for generic values of the relevant couplings. Then, also the physics of the cross over from non-critical to critical regimes is accessible. Complete integrability constitutes the crucial property that even exact correlation functions are available. Important steps forward to this goal have become possible by the Quantum Inverse Scattering approach [2], more recently refined by Kitanine, Maillet, Slavnov and Terras [3] and Korepin and Göhman [4].

The quantum anisotropic XY chains are a relevant example of completely integrable models. The model was solved exactly by Lieb, Schultz and Mattis [5], Pfeuty [6] for isotropic cases and by Barouch, McCoy, and Dresden [7] for generic anisotropy. Also the correlation functions were intensively studied and analytic expressions for their asymptotics (in time and space variables) were obtained [7,8]. The correlation functions were calculated at equilibrium and for time-dependent magnetic field. We perform an exact calculation of correlations between states that are not eigenstates of the model, and that therefore describe non-equilibrium properties of the model; we remark that the Hamiltonian instead does not contain explicit time-dependence. Our motivations come from condensed matter where quantum XY chains are particulary studied, even more intensively since recent interest in the phenomenon of decoherence in suitably designed physical systems [9]; this latter kind of analysis is due, in turn, to the burst of interest in quantum information theory [10]. Such cross-over of interests originated a line of research investigating the inter-connection between condensed matter and quantum information. In particular it is intriguing to investigate whether it is possible to better characterize condensed matter states by looking at e.g. quantum correlations entanglement properties of their wavefunction. Already a number of interesting results in this direction have been obtained [11]-[19].

The present paper is laid out as follows. In the next section we present the models we discuss and review the exact solution from Refs. [5,7], already preparing relevant building blocks for computing off-equilibrium correlations. In section III we present known results connecting vacuum expectation values in fermionic theories with a generalized determinant structure, called the Pfaffian and their application to equilibrium correlation functions presented in [6,7]. Section IV contains the main result for non-equilibrium correlations and matrix elements of the presented models. After all we draw our conclusions.

II. THE MODELS

The system under consideration is a spin-1/2 ferromagnetic chain with an exchange coupling λ in a transverse magnetic field of strength \( h \). The Hamiltonian is \( H = h H_s \) with the dimensionless Hamilton operator \( H_s \) being

\[
H_s = -\lambda \sum_{i=1}^{N} (1 + \gamma) S^x_i S^x_{i+1} + (1 - \gamma) S^y_i S^y_{i+1} - \sum_{i=1}^{N} S^z_i
\]  

(1)
where $S^a$ are the spin-1/2 matrices ($a = x, y, z$) and $N$ is the number of sites. We assume periodic boundary conditions. The anisotropy parameter $\gamma$ connects the quantum Ising model for $\gamma = 1$ with the isotropic XY model for $\gamma = 0$. In the interval $0 < \gamma \leq 1$ the model belongs to the Ising universality class and for $N = \infty$ it undergoes a quantum phase transition at the critical coupling $\lambda_c = 1$. The order parameter is the magnetization in $x$-direction, $\langle S^x \rangle$, which is different from zero for $\lambda > 1$ and vanishes at and below the transition. On the contrary the magnetization along the $z$-direction, $\langle S^z \rangle$, is different from zero for any value of $\lambda$.

This class of models was diagonalized by means of the Jordan-Wigner transformation [5–7] that maps spins to one dimensional spin-less fermions with creation and annihilation operators $c^\dagger_l$ and $c_l$. It proved convenient to use the operators $A_l = c^\dagger_l + c_l$, $B_l = c^\dagger_l - c_l$, which fulfill the anti-commutation rules

$$
\{A_l, A_m\} = -\{B_l, B_m\} = 2\delta_{lm} ,
\{A_l, B_m\} = 0 .
$$

In terms of these operators the Jordan-Wigner transformation reads

$$
S^x_l = \frac{1}{2} A_l \prod_{s=1}^{l-1} A_s B_s ,
S^y_l = -i \frac{1}{2} B_l \prod_{s=1}^{l-1} A_s B_s ,
S^z_l = -\frac{1}{2} A_l B_l .
$$

The Hamiltonian defined in Eq.(1) is bilinear in the fermionic degrees of freedom and therefore can be diagonalized by means of the transformation

$$
\eta_k = \frac{1}{\sqrt{N}} \sum_l e^{ikl} \left( \alpha_k c_l + i\beta_k c_l^\dagger \right) ,
$$

with coefficients

$$
\alpha_k = \frac{\Lambda_k - (1 + \lambda \cos k)}{\sqrt{2[\Lambda_k^2 - (1 + \lambda \cos k)\Lambda_k]}} ,
\beta_k = \frac{\gamma \lambda \sin k}{\sqrt{2[\Lambda_k^2 - (1 + \lambda \cos k)\Lambda_k]}} .
$$

The Hamiltonian thereafter assumes the form

$$
H = \sum_k \Lambda_k \eta_k^\dagger \eta_k - \frac{1}{2} \sum_k \Lambda_k
$$

and the associated energy spectrum is

$$
\Lambda_k = \sqrt{(1 + \lambda \cos k)^2 + \lambda^2 \gamma^2 \sin^2 k} .
$$

Now, in order to calculate correlations out of equilibrium, we need to know the time dependence of the relevant operators. From Eq.(4) we obtain the spin-less fermion creation and annihilation operators in the Heisenberg picture. We have $\eta_k^\dagger(t) = \exp(-i\Lambda_k t)\eta_k^\dagger(0)$ and hence, using Eq.(4) and its inverse

$$
c_j(t) = \sum_l [\tilde{a}_{l-j}(t)c_l - \tilde{b}_{l-j}(t)c_l^\dagger] ,
$$

where the new coefficients are

$$
\tilde{a}_x(t) = \frac{1}{\sqrt{N}} \sum_k \cos kx \left( e^{i\Lambda_k t} - 2i\beta_k^2 \sin \Lambda_k t \right) ,
\tilde{b}_x(t) = \frac{2i}{\sqrt{N}} \sum_k \sin kx \alpha_k \beta_k \sin \Lambda_k t .
$$
In the limit $\gamma = 0$ the previous expressions simplify considerably. In this case the magnetization, i.e. the $z$-component of the total spin $S_z = \sum_j S^z_j$, is a conserved quantity. In terms of fermions this corresponds to the conservation of the total number of particles, $N = \sum_j n_j = \sum_j c_j^\dagger c_j$. For $\gamma \to 0$ and $|\lambda| \leq 1$ we find that $\alpha_k \to 0$ and $\beta_k \to \text{sign} k$. The energy spectrum is $\Lambda_k = |1 + \lambda \cos k|$ and the eigenstates are plane waves (the Hamiltonian corresponds to a tight binding model)

$$c_j(t) = \frac{1}{\sqrt{N}} \sum_k \sum_l \cos k(l-j)e^{-i\Lambda_k t} c_l$$

$$\eta^\dagger_k = \frac{1}{\sqrt{N}} \sum_l e^{-i kl} c_l .$$

In this work we discuss vacuum expectation values and correlations in excitations of them. It is worthwhile noticing that different strategies are applied, depending on whether the vacuum is the ground state or the state with no particles (which we call the c-vacuum). Since it is cumbersome to calculate the time dependence of the vacuum itself, it is convenient to write the operators $A_l$ and $B_l$ in the Heisenberg picture. For the ground state instead the time dependence is trivial and the operators are taken in the Schrödinger picture. For both approaches we express the operators $A_l$ and $B_l$ in terms of the operators $\eta_k$ and $\eta^\dagger_k$

$$A_l = \frac{1}{\sqrt{N}} \sum_q \eta^\dagger_{l-q} \eta_q z_q e^{-iql}$$

$$B_l = \frac{1}{\sqrt{N}} \sum_q \eta^\dagger_{l-q} \eta_q z^*_q e^{-iql}$$

These are sufficient for the correlations in the ground state. For the calculation for the c-vacuum it proves to be convenient defining the following (redundant) Fourier transforms containing $\alpha_k$, $\beta_k$, and their combination $z_k := \alpha_k + i \beta_k$

$$\mathfrak{A}_x := \frac{1}{L} \sum_q dq \alpha^2 q e^{i q x}$$

$$\mathfrak{B}_x := \frac{1}{L} \sum_q dq \beta^2 q e^{i q x}$$

$$\mathfrak{Z}_x := \frac{1}{L} \sum_q dq \Lambda x e^{i q x}$$

$$\mathfrak{A}_3_x(t) := \frac{1}{L} \sum_q dq \alpha_q z_q e^{i \Lambda t e^{i q x}}$$

$$\mathfrak{B}_3_x(t) := \frac{1}{L} \sum_q dq \beta_q z_q e^{i \Lambda t e^{i q x}}$$

$$\mu_x(t) := \mathfrak{A}_3^*_x(t) - i \mathfrak{B}_3_x(t) .$$

In these quantities we have

$$A_l(t) = \sum_j \left( c_j^\dagger \mu_{j-l}(t) + c_j \mu_{j-l}^*(t) \right)$$

$$B_l(t) = \sum_j \left( c_j^\dagger \mu_{l-j}(t) - c_j \mu_{l-j}^*(t) \right) .$$

where

$$\mu_x(t) = \frac{1}{L} \sum_q dq e^{-i \Lambda t} (\alpha_q^2 \cos qx + \alpha_q \beta_q \sin qx) .$$
III. CORRELATION FUNCTIONS AS PFAFFIANS

It is known since 1952 that “vacuum” expectation values of a product of \(2R\) fermionic fields
\[
\langle 0| \Psi_1 \cdots \Psi_{2R} |0 \rangle
\]  
(22)
can be written as a Pfaffian \[20\]. The entries of the Pfaffian structure are the contractions of two field operators
\[
\langle 0| \Psi_i \Psi_j |0 \rangle = P_{i,j}.
\]  
(23)
The field operators \(\Psi\) are linear functionals of fermionic creation and annihilation operators, where the “vacuum” \(|0\rangle\) is that state annihilated by the annihilation operators. The Pfaffian is a type of generalized determinant form \[20\]. It is written in a triangular structure as
\[
\sum_{\pi \in S_{2n}^2} (-)^r P_{\pi(1),\pi(2)} P_{\pi(3),\pi(4)} \cdots P_{\pi(2n-1),\pi(2n)} = \begin{vmatrix}
P_{1,2} & P_{1,3} & \cdots & P_{1,R} & P_{1,R+1} & P_{1,R+2} & \cdots & P_{1,2R} \\
P_{2,3} & P_{2,4} & \cdots & P_{2,R} & P_{2,R+1} & P_{2,R+2} & \cdots & P_{2,2R} \\
\vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\
P_{R,R+1} & P_{R,R+2} & \cdots & P_{R,2R} & P_{R+1,R+2} & P_{R+1,2R} & \cdots & P_{2R-1,2R} \\
\end{vmatrix}
\]  
(24)
where \(S_{2n}^2\) denotes all elements \(\pi\) of the symmetric group \(S_{2n}\) which give ordered pairs; i.e. \(\pi(2l-1) < \pi(2l)\) and \(\pi(2l-1) < \pi(2m-1)\) for \(l < m\). We particularly make use of the known property that a Pfaffian can be expanded along “rows” or “columns”, where the \(r\)-th row or column corresponds to all \(P_{i,j}\) with \(i = r\) or \(j = r\). In analogy to matrix minors, we will call the minor Pfaffian \(\hat{P}_{i,j} = \hat{P}_{j,i}\) the Pfaffian of the above structure (24) when having canceled the \(i\)-th and \(j\)-th row. In terms of these minors the expansion reads
\[
P_{2R} = \sum_{i \neq r} (-)^{i+r} P_{i,r} \hat{P}_{i,r}.
\]  
(25)
where \(\hat{i,r}\) means that the indices are to be written in increasing order. It is worth noting that the \(r\)-th part of this expansion reflects all possible contractions with the field operator \(\Psi_r\) performed in Eq.(22).

There are two cases which we will study in this work: \(|0\rangle\) being (i) the ground state, denoted by \(|g\rangle\) and (ii) the c-vacuum, denoted by \(|\Psi\rangle\).

A. Ground state

At equilibrium \[5–7\], a crucial simplification is that \(\langle A_l A_m \rangle_g = -\langle B_l B_m \rangle_g = \delta_{lm}\). This reduces the Pfaffian to a Töplitz determinant
\[
\langle S_l^\alpha S_{l+R}^\alpha \rangle_g = s(\alpha, \alpha) \begin{vmatrix}
0 & \cdots & 0 & G_{1,1}^{\alpha \alpha} & G_{1,2}^{\alpha \alpha} & \cdots & G_{1,R}^{\alpha \alpha} \\
0 & \cdots & 0 & 0 & G_{R-1,1}^{\alpha \alpha} & \cdots & G_{R-1,R}^{\alpha \alpha} \\
0 & \cdots & 0 & 0 & G_{R,1}^{\alpha \alpha} & \cdots & G_{R,R}^{\alpha \alpha} \\
\end{vmatrix}
\]
\[
= (-)^{R(R-1)/2} s(\alpha, \alpha) \begin{vmatrix}
G_{1,1}^{\alpha \alpha} & \cdots & G_{1,R}^{\alpha \alpha} \\
\cdots & \cdots & \cdots \\
G_{R,1}^{\alpha \alpha} & \cdots & G_{R,R}^{\alpha \alpha} \\
\end{vmatrix}
\]  
(26)
with \[21\]
\[
G^{zz}_{\mu,\nu} = (A_{l+\mu}B_{l+\nu-1})_g \\
G^{y\gamma}_{\mu,\nu} = (A_{l+\mu-1}B_{l+\nu})_g
\]
\[
\langle A_lB_m \rangle_q = 3_{m-t}. \text{ The correlation functions } \langle S_l^y S_{l+R}^y \rangle \text{ and } \langle S_l^y S_{l+R}^z \rangle \text{ identically vanish, since a complete row and column in the corresponding matrices vanishes, respectively.}
\]
\]

As already mentioned, time-dependent correlation functions were derived in Ref. \[7\]. There, the time-dependence was explicitly induced into the Hamiltonian (time dependent external magnetic field). In contrast, we compute matrix elements of operators at non-equilibrium, meaning that the initial and final state are not eigenstates of the Hamiltonian; the resulting quantities are then time dependent although the Hamiltonian is not. First, we consider matrix elements in the \(c\)-vacuum \(|\psi\rangle\) (for generic \(\gamma\) this is not an eigenstate of the Hamiltonian; only for \(\gamma = 0\) it coincides with the ground state), and in excitations on it and on the ground state.

### A. Correlations in the \(c\)-Vacuum

Using Eqs. (19,20), leads to the following contractions as building blocks for the Pfaffians

\[
\langle A_l(t)B_m(t) \rangle_q = \sum_j \mu_j^{l-j}\mu_{m-j} = \\
\delta_{lm} - \frac{1}{L} \sum_q (2\alpha_q^2\beta_q^2 \cos q(m-l) + \alpha_q\beta_q(1 - 2\beta_q^2) \sin q(m-l)) \sin^2 \Lambda_q t
\]
\[
\langle A_l(t)A_m(t) \rangle_q = \sum_j \mu_j^{l-j}\mu_{j-m} = \delta_{lm} - 2i \frac{1}{L} \sum_q \alpha_q\beta_q \sin q(m-l) \sin 2\Lambda_q t
\]
\[
\langle B_l(t)B_m(t) \rangle_q = \sum_j \mu_j^{l-j}\mu_{m-j} = -\delta_{lm} - 2i \frac{1}{L} \sum_q \alpha_q\beta_q \sin q(m-l) \sin 2\Lambda_q t
\]

We are now ready to write down the two-point spin correlation functions, applying the results from the previous section

\[
\langle S_l^\alpha S_{l+R}^\beta \rangle_q = s(\alpha, \beta).
\]

\[
\begin{array}{cccccccccc}
I_1^{\alpha\beta} & \cdots & I_{l-1,R}^{\alpha\beta} & J_1^{\alpha\beta} & F_1^{\alpha\beta} & G_1^{\alpha\beta} & \cdots & \cdots & \cdots & G_{1,R}^{\alpha\beta} \\
\vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \ddots \\
I_R^{\alpha\beta} & \cdots & I_{R-2,R-1}^{\alpha\beta} & J_R^{\alpha\beta} & F_R^{\alpha\beta} & G_R^{\alpha\beta} & \cdots & \cdots & \cdots & G_{R-2,R}^{\alpha\beta} \\
J_1^{\alpha\beta} & \cdots & J_{R-1,R-1}^{\alpha\beta} & F_1^{\alpha\beta} & G_1^{\alpha\beta} & \cdots & \cdots & \cdots & \cdots & \cdots \\
\vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \ddots \\
J_R^{\alpha\beta} & \cdots & J_{R-1,R-1}^{\alpha\beta} & F_R^{\alpha\beta} & G_R^{\alpha\beta} & \cdots & \cdots & \cdots & \cdots & \cdots \\
E^{\alpha\beta} & \cdots & E^{\alpha\beta} & D_2^{\alpha\beta} & D_2^{\alpha\beta} & \cdots & \cdots & \cdots & \cdots & \cdots \\
K_1^{\alpha\beta} & \cdots & K_1^{\alpha\beta} & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
H_2^{\alpha\beta} & \cdots & H_2^{\alpha\beta} & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \ddots \\
H_{R-1,R}^{\alpha\beta} & \cdots & H_{R-1,R}^{\alpha\beta} & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\end{array}
\]

IV. CORRELATION FUNCTIONS OUT OF EQUILIBRIUM

As already mentioned, time-dependent correlation functions were derived in Ref. \[7\]. There, the time-dependence was explicitly induced into the Hamiltonian (time dependent external magnetic field). In contrast, we compute matrix elements of operators at non-equilibrium, meaning that the initial and final state are not eigenstates of the Hamiltonian; the resulting quantities are then time dependent although the Hamiltonian is not. First, we consider matrix elements in the \(c\)-vacuum \(|\psi\rangle\) (for generic \(\gamma\) this is not an eigenstate of the Hamiltonian; only for \(\gamma = 0\) it coincides with the ground state), and in excitations on it and on the ground state.
where \( s(x, x) = s(y, y) = 1/4(-R^{(R+1)/2}) \),

\[
\begin{align*}
I^{xx}_{\mu,\nu} &= \langle A_{t+\mu}(t)A_{t+\nu}(t) \rangle_\varphi \\
J^{xx}_\mu &= I^{xx}_{\mu,R} \\
H^{xx}_{\mu,\nu} &= \langle B_{t+\mu-1}(t)B_{t+\nu-1}(t) \rangle_\varphi \\
K^{xx}_\nu &= H^{xx}_{1,\nu} \\
G^{xx}_{\mu,\nu} &= \langle A_{t+\mu}(t)B_{t+\nu-1}(t) \rangle_\varphi \\
F^{xx}_\mu &= G^{xx}_{\mu,1} \\
E^{xx} &= G^{xx}_{R,1} \\
D^{xx}_\nu &= G^{xx}_{R,\nu}
\end{align*}
\]

(33)

and \( s(x, y) = s(y, x) = -i/4(-R^{(R-1)/2}) \),

\[
\begin{align*}
I^{yy}_{\mu,\nu} &= \langle A_{t+\mu-1}(t)A_{t+\nu-1}(t) \rangle_\varphi \\
J^{yy}_\mu &= I^{yy}_{\mu,R} \\
H^{yy}_{\mu,\nu} &= \langle B_{t+\mu}(t)B_{t+\nu}(t) \rangle_\varphi \\
K^{yy}_\nu &= H^{yy}_{1,\nu} \\
G^{yy}_{\mu,\nu} &= \langle A_{t+\mu-1}(t)B_{t+\nu}(t) \rangle_\varphi \\
F^{yy}_\mu &= G^{yy}_{\mu,1} \\
E^{yy} &= G^{yy}_{R,1} \\
D^{yy}_\nu &= G^{yy}_{R,\nu}
\end{align*}
\]

(34)

\[
\begin{align*}
I^{xy}_{\mu,\nu} &= \langle A_{t+\mu}(t)A_{t+\nu}(t) \rangle_\varphi \\
G^{xy}_{\mu,\nu} &= \langle A_{t+\mu}(t)B_{t+\nu}(t) \rangle_\varphi \\
J^{xy}_\mu &= G^{xy}_{\mu,0} \\
F^{xy}_\mu &= G^{xy}_{\mu,1} \\
H^{xy}_{\mu,\nu} &= \langle B_{t+\mu-1}(t)B_{t+\nu-1}(t) \rangle_\varphi \\
E^{xy} &= H^{xy}_{0,1} \\
D^{xy}_\nu &= H^{xy}_{0,\nu} \\
K^{xy}_\nu &= H^{xy}_{1,\nu}
\end{align*}
\]

(35)
I_{\mu,\nu}^{yx} = \langle A_{t+\mu-1}(t) A_{t+\nu-1}(t) \rangle_{q}
G_{\mu,\nu}^{yx} = \langle A_{t+\mu-1}(t) B_{t+\nu-1}(t) \rangle_{q}
J_{\mu}^{yx} = I_{\mu,R}^{yx}
F_{\mu}^{yx} = I_{\mu,R+1}^{yx}
E_{\nu}^{yx} = I_{R,R+1}^{yx}
D_{\nu}^{yx} = G_{R,\nu}^{yx}
K_{\nu}^{yx} = G_{R+1,\nu}^{yx}
H_{\mu,\nu}^{yx} = \langle B_{t+\mu-1}(t) B_{t+\nu-1}(t) \rangle_{q}

(36)

We note that a Pfaffian $P$ can be written (up to a sign) as a determinant of the corresponding antisymmetric matrix $A$ of dimension $2R \times 2R$ [22] by $|pf P|^2 = \det A$. Since the $c$-vacuum is transactional invariant this determinant is again of Töplitz type. Therefore, also here the asymptotics of the correlation functions could be extracted explicitly along the lines depicted in [7].

**B. Matrix elements for excitations of the vacuum**

We now want to concentrate on expectation values for states which are not the vacuum. So let $C^\dagger$ and $C'^\dagger$ be linear functionals in the creation and annihilation operators and let us calculate

$$\langle C | \Psi_1 \cdots \Psi_{2R} | C' \rangle := \langle 0 | C \Psi_1 \cdots \Psi_{2R} C'^\dagger | 0 \rangle$$

(37)

Performing all possible contractions in (37), we obtain $\langle 0 | C C'^\dagger | 0 \rangle \langle 0 | \Psi_1 \cdots \Psi_{2R} | 0 \rangle + \text{all possible contractions where } C \text{ and } C'^\dagger \text{ are contracted with a pair of field operators, say } \Psi_i \text{ and } \Psi_j$. Thus we have to calculate

$$\hat{P}_{i,j} := \langle C | \Psi_i | 0 \rangle \langle 0 | \Psi_j | C' \rangle - \langle C | \Psi_j | 0 \rangle \langle 0 | \Psi_i | C' \rangle,$$

(38)

where we take $i < j$ in order to avoid double counting of contractions. The sign coming from transporting the operators $C$ and $C'^\dagger$ to the left of $\Psi_i$ and the right of $\Psi_j$ respectively is $(-1)^{i+j+1}$. In the remaining vacuum expectation value the field operators $\Psi_i$ and $\Psi_j$ are missing, which corresponds to canceling the rows $i$ and $j$ in the original Pfaffian (24). Consequently, this expectation value is the minor Pfaffian $\hat{P}_{i,j}$, and we obtain

$$\langle C | \Psi_1 \cdots \Psi_{2R} | C' \rangle := \mathcal{P}_{2R} + \sum_{i=1}^{2R-1} \sum_{j=i+1}^{2R} (-1)^{i+j+1} \hat{P}_{i,j} \hat{P}_{i,j} \rangle =$$

$$= \mathcal{P}_{2R} + \sum_{i=1}^{2R-1} \left( \sum_{j=1}^{i-1} (-1)^{i+j+1} \hat{P}_{i,j} + \sum_{j=i+1}^{2R} (-1)^{i+j+1} \hat{P}_{i,j} \right) \hat{P}_{i,j} \rangle$$

We note that this expression is the sum over Pfaffian expansions (25). Indeed, each element of the first sum is the expansion of a Pfaffian along the $i$-th row, in which $P_{j,i} = 0$ and $P_{i,j} \rightarrow \hat{P}_{i,j}$, hence

$$\langle C | \Psi_1 \cdots \Psi_{2R} | C' \rangle := \sum_{i=0}^{2R-1} \mathcal{P}^{(i)}_{2R},$$

(39)

where we defined

$$\mathcal{P}^{(0)}_{2R} := \mathcal{P}_{2R}$$
and

\[ \mathcal{P}_{2R}^{(i)} := \begin{vmatrix} P_{1,2} & \ldots & 0 & P_{1,i+1} & \ldots & P_{1,2R} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ 0 & P_{t-1,i+1} & \ldots & P_{t-1,2R} & \ldots & P_{t-1,2R} \\ \vdots & \vdots & \ddots & \ddots & \vdots & \vdots \\ P_{t,i+1} & \ldots & \ldots & P_{t,2R} & \ldots & P_{t,2R} \\ P_{2R-1,i+1} & \ldots & \ldots & \ldots & \ldots & P_{2R-1,2R} \end{vmatrix} \]  

(40)

Actually, we found the correlations \( \langle C | S^\alpha_{l} S^\beta_{l+R} | C' \rangle \) expressed as a sum of Pfaffians. The generalization to operators \( C^\dagger \) that are multi-linear in the annihilation and creation operators can be related to a sum of multi-row expanded Pfaffians [23].

In what follows, we will come back to the cases of the ground state and the c-vacuum, discussed in the previous section. As mentioned, in order to be able to explicitly extract the asymptotics of the correlations, the initial and final state have to be transactional invariant. In the following, the translational invariance is explicitly broken.

1. Single hole excitations on the ground state

We choose the final and initial state to be \( \langle C | = \langle g | c_j^\dagger / \sqrt{\mathcal{B}_0} =: \langle j | \text{ and } | C' \rangle = c_k | g \rangle / \sqrt{\mathcal{B}_0} =: | k \rangle \), which is normalized due to \( \langle g | c_j^\dagger c_k | g \rangle = \mathcal{B}_{k-j} \). Then we have to calculate

\[ \langle A_l B_m \rangle_g^{jk} = \langle j | A_l | g \rangle \langle g | B_m | k \rangle - \langle j | B_m | g \rangle \langle g | A_l | k \rangle \]

In this case we find

\[ \langle A_l B_m \rangle_g^{jk} = \frac{\mathcal{B}_j \mathcal{B}_{m-k} + \mathcal{B}_{m-j} \mathcal{B}_{k-l}}{\mathcal{B}_0} \]  

(41)

\[ \langle A_l A_m \rangle_g^{jk} = \frac{\mathcal{B}_j \mathcal{B}_{k-m} - \mathcal{B}_{k-j} \mathcal{B}_{j-m}}{\mathcal{B}_0} \]  

(42)

\[ \langle B_l B_m \rangle_g^{jk} = - \frac{\mathcal{B}_j \mathcal{B}_{m-k} - \mathcal{B}_{m-j} \mathcal{B}_{k-m}}{\mathcal{B}_0} \]  

(43)

The contraction of \( C \) with \( C' \) is

\[ \langle 0 | CC' | 0 \rangle = \frac{\mathcal{B}_{k-j}}{\mathcal{B}_0} \]  

(44)

We now discuss the correlation functions \( \langle S^\alpha_{l} S^\alpha_{l+R} \rangle \). The only non-zero contributions come from contractions of \( C \) and \( C' \) with one operator of type \( A \) and one of type \( B \) (since only vacuum expectations of an equal number of \( A \)’s and \( B \)’s are non-zero as discussed before). That means that here the sum of Pfaffians simplifies to the following sum of determinants

\[ \langle S^\alpha_{l} S^\alpha_{l} \rangle = \sum_{i=1}^{R} \mathcal{D}_{R}^{(i)} \]

with

\[ \mathcal{D}_{R}^{(i)} = (-1)^R \begin{vmatrix} G_{1,1}^{\alpha \alpha} & \ldots & G_{1,R}^{\alpha \alpha} \\ \vdots & \ddots & \vdots \\ G_{i,1}^{\beta \beta} & \ldots & G_{i,R}^{\beta \beta} \\ \vdots & \ddots & \vdots \\ G_{R,1}^{\gamma \gamma} & \ldots & G_{R,R}^{\gamma \gamma} \end{vmatrix} \]  

(45)

with

\[ G_{\mu,\nu}^{xx} = \langle A_{i+\mu} B_{i+\nu-1} \rangle_g \]  

(46)

\[ \tilde{G}_{\mu,\nu}^{xx} = \langle A_{i+\mu} B_{i+\nu-1} \rangle_g \]  

(47)

\[ G_{\mu,\nu}^{yy} = \langle A_{i+\mu-1} B_{i+\nu} \rangle_g \]  

(48)

\[ \tilde{G}_{\mu,\nu}^{yy} = \langle A_{i+\mu-1} B_{i+\nu} \rangle_g \]  

(49)
Analogously, for the correlation functions \( \langle S^x_I S^y_R \rangle \) and \( \langle S^y_I S^x_R \rangle \) the only non-zero contributions come from contractions of \( C \) and \( C' \) with two operators of type \( \hat{B} \) and two of type \( \hat{A} \), respectively. This again simplifies the sum of Pfaffians to a sum of determinants

\[
\langle S^x_I S^y_R \rangle = \sum_{i=1}^{R} \mathcal{P}^{(i)}_{2R},
\]

where

\[
\mathcal{P}^{(i)}_{2R} = \begin{vmatrix}
0 & \ldots & 0 & G^{xy}_{1,1} & \ldots & 0 & G^{xy}_{1,i+1} & \ldots & G^{xy}_{1,R+1} \\
\vdots & \ddots & \vdots & \ddots & \vdots & \ddots & \vdots & \ddots & \vdots \\
0 & G^{xy}_{R-1,1} & \ldots & 0 & G^{xy}_{R-1,i+1} & \ldots & G^{xy}_{R-1,R+1} \\
0 & \ldots & 0 & 0 & \ldots & 0 & \ldots & 0 & 0 \\
0 & \ldots & 0 & \ldots & 0 & \ldots & 0 & \ldots & 0
\end{vmatrix}
\]

(50)

and this simplifies to

\[
\langle S^x_I S^y_R \rangle = \sum_{i=1}^{R} \mathcal{D}^{(i)}_{R}
\]

with

\[
\mathcal{D}^{(i)}_{R} = (-1)^R \begin{vmatrix}
G^{xy}_{1,1} & \ldots & G^{xy}_{1,i-1} & G^{xy}_{1,i+1} & \ldots & G^{xy}_{1,R+1} \\
\vdots & \ddots & \vdots & \ddots & \vdots & \ddots & \vdots \\
G^{xy}_{R-1,1} & \ldots & G^{xy}_{R-1,i-1} & G^{xy}_{R-1,i+1} & \ldots & G^{xy}_{R-1,R+1} \\
0 & \ldots & 0 & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
0 & \ldots & 0 & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
\hat{H}_{i,i+1}^{xy} & \ldots & \hat{H}_{i,R+1}^{xy}
\end{vmatrix}
\]

(51)

with

\[
G^{xy}_{\mu,\nu} = \langle A_{t+\mu} B_{t+\nu-1} \rangle_g \\
\hat{H}_{\mu,\nu}^{xy} = \langle B_{t+\mu-1} B_{t+\nu-1} \rangle_{jk}^g
\]

(52)

(53)

In an analogous way we find

\[
\langle S^y_I S^x_R \rangle = \sum_{i=1}^{R} \mathcal{D}^{(i)}_{R}
\]

with \( \mathcal{D}^{(i)}_{R} \) defined as in (51), but

\[
G^{xy}_{\mu,\nu} = \langle A_{t+\nu-1} B_{t+\mu} \rangle_g \\
\hat{H}_{\mu,\nu}^{xy} = \langle A_{t+\mu-1} A_{t+\nu-1} \rangle_{jk}^g
\]

(54)

(55)

2. Single particle excitations on the ground state

Alternatively we consider \( \langle C \rangle = \langle g | c_j / \sqrt{A_0} = : j | \rangle \) and \( \langle C' \rangle = c_k^\dagger | g \rangle / \sqrt{A_0} = : k | \rangle \) as final and initial state, which are again normalized according to \( \langle g | c_j^\dagger c_k | g \rangle = \delta_{k-j} \). In this case the possible contractions with the operators \( C \) and \( C' \) are
The contraction of $C$ are replaced with given by Eqs. (32)–(36), where (following Eq. 40) in the $i$ and in the same manner problem to find the asymptotics of the correlations since the Szegö theorem cannot be applied. This last issue constitutes a further difficulty of the correlation functions in excited states (of the vacuum) the translational invariance of the system is explicitly broken the vacuum-correlation functions the Pfaffians instead, they can be related to $2$\[\langle C|S^x(t=0)|C'\rangle = \langle C|S^y(t=0)|C'\rangle = 0.\]

3. Single particle excitations on the c-vacuum

We take the final and initial state to be $|C\rangle = |0\rangle c_j =: |j\rangle$ and $|C'\rangle = c_k^\dagger =: |k\rangle$. In this case the Pfaffian $P^R_{2R}$ is given by Eqs. (32)–(36), where (following Eq. 40) in the $i$-th row
\[\langle \psi | A_i B_m | \psi \rangle \rightarrow \langle A_i B_m \rangle^j_k\]
are replaced with
\[\langle A_i B_m \rangle^j_k \equiv \langle j | A_i | \psi \rangle \langle \psi | B_m | k \rangle - \langle j | B_m | \psi \rangle \langle \psi | A_i | k \rangle\]
and in the same manner $\langle \psi | A_i A_m | \psi \rangle \rightarrow \langle A_i A_m \rangle^j_k$, $\langle \psi | B_i B_m | \psi \rangle \rightarrow \langle B_i B_m \rangle^j_k$. We find
\[\langle A_i(t)B_m(t) \rangle^j_k = - (\mu_m - j\mu_k^* - l + \mu_j - l\mu_k^* - k) \] (60)
\[\langle A_i(t)A_m(t) \rangle^j_k = \mu_j - l\mu_k^* - m - \mu_j - m\mu_k^* - l \] (61)
\[\langle B_i(t)B_m(t) \rangle^j_k = \mu_m - j\mu_k^* - m - \mu_j - l\mu_k^* - k \] (62)
With these results, all spin-correlation functions can be calculated as long as $\langle C|S^x(t=0)|C'\rangle = \langle C|S^y(t=0)|C'\rangle = 0$. In this case it will remain zero during the evolution. This is satisfied if the parity symmetry of the Hamiltonian is not broken by neither the initial nor the final state.

V. CONCLUSIONS

We calculated exactly spin-spin correlations out of equilibrium. For excitations on the “vacuum”, they can be written as a sum of Pfaffians. For excitations on the ground state these Pfaffians reduce to determinants (see Eqs. (39), (40)). The result for particle and hole excitations on the ground state and the $c$-vacuum were based on different approaches, writing the fermionic field operators in the Schrödinger and Heisenberg picture, respectively. Comparing with the known eigenstate correlations, we remark that here $\langle S^x(t=0)S^y(t=0)\rangle$ cannot be reduced to $R \times R$ Töplitz determinants. For the vacuum-correlation functions the Pfaffians instead, they can be related to $2R \times 2R$ Töplitz determinants. For correlation functions in excited states (of the vacuum) the translational invariance of the system is explicitly broken and then the determinants are not anymore of Töplitz type. This last issue constitutes a further difficulty of the problem to find the asymptotics of the correlations since the Szegö theorem cannot be applied.

We have used these results explicitly for studying the dynamics of correlations and quantum information theoretic quantities like the entanglement in specific states [19] but is also a key ingredient for the study of transport properties of the system. One possible application of the exact results we found here is to study the quantum phase transitions (characteristic of this class of models) out of equilibrium.
