**ABSTRACT**

**Background:** The present study was designed to investigate the hepatoprotective effect of methanolic extract of *Ficus religiosa* L., Moraceae, on isoniazid-rifampicin and paracetamol induced hepatotoxicity in rats. **Materials and Methods:** Male Wistar albino rats were divided into six groups; group 1 served as a control received vehicle (Distilled water), group 2 served as a toxic control, received isoniazid-rifampicin (100 mg/ kg, i.p.) or paracetamol 200mg/kg, p.o in sterile water, groups 3, 4 and 5 received 100, 200 and 300mg/kg bw, p.o. methanolic extract of *F. religiosa* along with INH+RIF or paracetamol and group 6 received Liv 52 as reference standard. All the treatment protocols followed 21 days for INH+RIF model and seven days for paracetamol model, after treatment rats were sacrificed and blood was used for biochemical and liver was used for histological studies. **Results:** Administration of INH+RIF and paracetamol caused a significant elevation in the levels of liver marker enzymes ($P < 0.05$ and $P < 0.01$) and thiobarbituric acid reactive substances ($P < 0.001$) in experimental rats. Administration of methanolic extracts of *F. religiosa* significantly prevented isoniazid-rifampicin and paracetamol induced elevation in the levels of serum diagnostic liver marker enzymes and TBARS level in experimental groups of rats. Moreover, total protein and reduced glutathione levels were significantly ($P < 0.001$) increased in treatment group. The effect of extract was compared with a standard drug, Liv 52. The changes in biochemical parameters were supported by histological profile. **Conclusion:** The methanolic extract of *F. religiosa* protects against isoniazid-rifampicin and paracetamol induced oxidative liver injury in rats.

**Key words:** Drug induced liver injury, Flavonoids, hepatotoxin, oxidative stress

**INTRODUCTION**

Liver is a key organ that regulates metabolism, secretion, storage, and detoxifying functions in the body, and hepatic damage is often associated with distortion of these functions. Drug-induced liver toxicity is a common cause of liver injury. It accounts for approximately one-half of the cases of acute liver failure and mimics all forms of acute and chronic liver disease.[1] Different types of drugs such as acetaminophen, chloroquine and isoniazid are inducers of hepatotoxicity in world. Most of the hepatotoxic chemicals damage liver cells mainly by inducing lipid peroxidation and other oxidative damages. Liver possesses a unique metabolism and plays a pivotal role in the removal of substances from the portal circulation due to which it is susceptible to toxicity of drugs, xenobiotics, and oxidative stress. The current treatment for hepatotoxicity includes drugs which influence the p-450 enzyme mechanism either by inhibiting (amiodarone, cimetidine, ciprofloxacin, etc.) or inducing (rifampicin, carbamazepine, phenobarbital, phenytoin) the metabolic activity of enzymes.[2] Herbal medicines have put forward a number of formulations for liver disorders. In this modern age it is very important to provide scientific proof to justify the various medicinal uses of herbs.[3]

*Ficus religiosa* (Moraceae) commonly known as Bodhi tree is regarded as a sacred tree to both Hindus as well as Buddhists; it is used for medicinal as well as religious purposes in India.[4] In Ayurveda it is claimed that *Ficus religiosa* possesses anticonvulsant activity.[5] Many such
reports have been validated pharmacologically for its actions on CNS viz.: different parts of *Ficus religiosa* showed acetyl cholinesterase inhibitory activity[8] and antianxiety activity.[7] Fruits of this plant contain numerous amino acids like asparagine and tyrosine in fruit edible part, alanine, threonine, tyrosine, and valine in seeds, alanine and valine in proteins.[8] Apart from amino acids fruits of this plant has been reported to contain highest amount of serotonin (5-HT) as compare to fruits of other *Ficus* species.[9,10] Singh et al.,[11] reported the anticonvulsant activity of methanolic extract of *Ficus religiosa*. The aqueous extract of leaves was reported for Antidiabetic activity by Srinivasan BP et al.[12] The hepatoprotective activity is not yet evaluated in this plant but most of the *ficus* species were reported for hepatoprotective activity.[13] Hence the present study was undertaken to investigate hepatoprotective role of methanolic extract of *Ficus religiosa* leaves by isoniazid, rifampicin (INH+RIF) and paracetamol (PML) induced hepatotoxic model.

**MATERIALS AND METHODS**

**Chemicals**

Bilirubin, total protein, alkaline phosphatase (ALP), alanine transaminases (ALT), and aspartate transaminases (AST) were assayed by using kits from Ranbaxy Diagnostic, New Delhi. All the drugs, chemicals and reagents used for biochemical estimation were purchased from Sigma-Aldrich, USA.

**Animals**

Male Wistar albino rats, weighing about 150-200g and Swiss albino mice weighing about 25-30g were obtained from Institute Animal Center were used in the experiments. The protocol was approved by the Institute's Animal Ethical Committee (1220/a/08/CPCSEA/ANCP/04). Animals were kept in the animal house at an ambient temperature of 25°C and 45-55% relative humidity, with 12 hrs each of dark and light cycles. Animals were fed pellet diet and water ad-libitum.

**Plant material and preparation of extract**

The leaves of *Ficus religiosa* Linn were freshly collected in the month of August-September 2009 in and around of Rajampet, Andhra Pradesh, India. The plant materials were identified and authenticated by Dr. K. Madhava Chetty, Department of botany, Sri Venkateswara University, Tirupathi. The vide voucher specimen (ANCP-Medicinal Plants-019-2011) has been deposited in the department. Authenticated leaves were washed with water, shade-dried, ground to a moderately coarse powder. The powdered leaves were subjected to extraction by refluxing with methanol in a Soxhlet extractor for 72 hrs. The resultant extract was evaporated to dryness using rotavapor (Evator rotary vacuum evaporator EV111) and stored at 4°C (yield: 5.3%, w/w).

**Phytochemical screening**

The obtained extracts were subjected to preliminary phytochemical screening and thin layer chromatography to identify the chemical constituents. TLC was performed by using mobile phase Benzene: Chloroform in the ratio of 7:3 and the compound were detected under UV chamber at 365 nm. The methods of analysis employed were those described in standard procedures.[14,15]

**Hepatotoxicity induced by isoniazid and rifampicin**

Isoniazid and rifampicin solution were prepared separately in sterile distilled water. Rats were treated with isoniazid (100 mg/kg, i.p.) and co-administered with rifampicin (100 mg/kg, i.p.), for 21 days.[16,17] In order to study the effect of MEFR in rat, 100, 200 and 300 mg/kg bw, p.o. were used respectively. Liv 52 (10 mg/kg bw, p.o) was used as a standard drug in this study. Rats were divided into Six different groups (n = 6), group 1 was served as a control, group 2 was toxic control receive isoniazid+rifampicin (100 mg/kg bw i.p.), group 3 served as standard group received Liv 52 and group 4, 5 and 6 were served as extract treatment groups received 100, 200 and 300 mg/kg bw, p.o MEFR. Rats were treated as per the treatment protocol. Body weights of these rats were monitored sequentially in control and experimental animals for a period of 21 days.

**Hepatotoxicity induced by paracetamol**

Rats were divided into Six different groups (n = 6), group 1 was served as a control, group 2 was toxic control receive paracetamol (200 mg/kg bw p.o), group 3 served as standard group received Liv 52. and group 4, 5 and 6 were served as extract treatment groups received 100, 200 and 300 mg/kg bw, p.o MEFR. Rats were treated as per the treatment protocol. Body weights of these rats were monitored sequentially in control and experimental animals for a period of 7 days. They were sacrificed 1hr after administration on seventh day and the blood was collected by retro orbital artery bleeding. Blood samples were kept for 30 minutes without any disturbance in dry test tubes. Then the supernatant layer was centrifuged for 10 minutes at 3000 rpm to separate the serum.

**Biochemical estimation**

Rats were sacrificed 1hr after administration on day 21 for isoniazid-rifampicin model and seventh day for paracetamol model. The blood was collected by retro-orbital artery bleeding. Blood samples were centrifuged for 10 min at 3000 rpm to separate the serum. ALP, ALT, AST, total protein and bilirubin levels were estimated from the serum by using standard kits. Liver was excised immediately,
quickly cooled and perfused with cold normal saline. Ten percent homogenate was prepared by homogenizing the liver tissue by using 0.3 m phosphate buffer. TBARS[18] and GSH[19] levels were estimated from the liver homogenate by using spectrophotometric determination.

**Histopathological studies**

The tissues of liver were fixed in 10% formalin and embedded in paraffin wax. Sections of 4-5 microns thickness were made using rotary microtome and stained with haematoxylin-eosin and histological observations were made under light microscope.

**Statistics**

All values were expressed as means ± SEM (n = 6 in each group). One way ANOVA was applied to test for significance of biochemical data of the different groups. Significance is set at $P \leq 0.05$.

**RESULTS**

**Phytochemical screening**

Phytochemical screening of MEFR revealed the presence of triterpenoids, alkaloids, flavonoids and phenolic compound. TLC of plant extract produced pink fluorescent compounds at 365nm and $R_f$ value was 0.2, 0.36 and 0.58 [Figure 1].

**Acute toxicity activity**

Acute oral toxicity studies, the extracts treated animals were observed for mortality up to 48 hrs. There was no mortality or any signs of behavioral changes observed after oral administration of methanol extract up to 5000 mg/kg body weight.

**Isoniazid — rifampicin and paracetamol induced hepatotoxicity**

The results of biochemical parameters revealed the elevation of biochemical markers like SGPT and SGOT in toxicant treated group indicating that INH+RIF and PM induces damage to the liver. Pretreatment with methanolic extract of *Ficus* religiosa at three different doses significantly reduced ($P < 0.01$) the elevated levels of SGPT and SGOT. There is no significant different in toxicant group as well as extract treatment group for the level of Total protein and albumin and alkaline phosphatase. The extract of *Ficus religiosa* treated rats when compared with standard Liv 52 group and extract control group there was no significant different in biochemical parameters. The results were present in Table 1 and 2.

**Histopathological studies**

Histopathological examination of the liver section of the rats treated with INH+RIF and PM showed an intense centrilobular necrosis and vacuolization. The rats treated with Liv 52 and methanolic extract of *Ficus religiosa* showed a good sign of protection against the toxicant to considerable extent as it was evident from the formation of normal hepatic cords and absence of necrosis and vacuoles [Figures 2 and 3].

**DISCUSSION**

From the phytochemical investigation the methanolic extract contains flavonoid was proved by chemical test and TLC. In UV chamber the compound shows pink fluorescent indicating the presence of flavonoids rich in the extract. During the metabolism of INH, hydrazine is produced directly (from INH) or indirectly (from acetyl hydrazine). From earlier study[20] it is evident that hydrazine play a role in INH induced liver damage in rats.

parameswari, et al.: hepatoprotective activity of ficus religiosa leaves

which is consistent with the report by sarich et al[21]. the combination of inh and rif was reported to result in higher rate of inhibition of biliary secretion and an increase in liver cell lipid peroxidation, and cytochrome p450 was thought to be involved the synergistic effect of rif on inh.[22] however, its role in inh induced hepatotoxicity is not clear, because, inh itself is an inducer of cyp2e1.[21] according to previous report it is cleared that inh itself does not produce complete damage to the liver.[23,24] inh is metabolized in the liver primarily by acetylation and hydrolysis, and these acetylated metabolites are thought to be hepatotoxins.[25,26] previous report in rats suggest that the hydrazine metabolite of inh is subsequent effect on cyp2e1 induction is involved in the development of inh-induced hepatotoxicity.[27] and also oxidative stress as one of the mechanism for inh+rif induced hepatic injury.[27]

acetaminophen was metabolically activated by cytochrome p450 enzymes to a reactive metabolite that depleted glutathione (gsh) and covalently bound to protein. it was shown that repletion of gsh prevented the toxicity. the reactive metabolite was found to be n-acetyl-p-benzoquinone imine (napqi), which is formed by a direct two-electron oxidation.[28] more recently, the cytochromes 2e1, 1a2, 3a4, and 2a6[29-31] have been reported to oxidize acetaminophen to the reactive metabolite. acetaminophen toxicity increased formation of superoxide would lead to

hydrogen peroxide and peroxidation reactions by Fenton-type mechanisms.

In this study the results suggest that the statistically significant difference in biochemical parameters in toxic control group G2, indicate that hepatic damage has been induced by INH+RIF and paracetamol. Following treatment with Liv 52 and MEFR (100, 200 and 300 mg/kg), all the parameters were reduced and total protein restored to normal value. Thakare et al.[32] also reported that administration of methanolic extract of *F. Religiosa* revert the elevated level of serum liver marker enzymes and malondialdehyde (MDA) (an index of lipid per oxidation) formation in edematous tissue at a dose of 200 and 400 mg/kg.

Histopathology also revealed that the significant protection from the hepatic damage by the treatment of MEFR. Metabolism of chemicals takes place largely in the liver, which accounts for the organ’s susceptibility to metabolism-dependent, drug induced injury. The drug metabolites can be electrophilic chemicals or free radicals that undergo or promote a variety of chemical reactions, such as depletion of reduced glutathione; covalently binding to proteins, lipids, or nucleic acids; or inducing lipid peroxidation.[1]

In present study in toxic control group increased level of TBARS (a marker for oxidative stress), reduction in the GSH concentration is indication for increased oxidative stress in INH+RIF and paracetamol treatment group. Elevation of TBARS were significantly reduced by co-administration of MEFR and Liv 52 and elevation of GSH level after MEFR and Liv 52 treatments indicate that the extracts is useful for the treatment of drug injury caused by INH+RIF and paracetamol. Recently we have reported the similar type of protective role of ficus benghalensis in INH+RIF induced hepatotoxicity model.[33]

The correlation between antioxidant activities and quantity of the flavonoids is still under discussion, a good linear relationship was observed in some published works.[34] Number of medicinal plants has been reported with good hepatoprotective activity with potential antioxidative mechanism due to presence of flavonoids and phenolic compounds.[35-37] The protective role of this plant against liver toxicity might be through antioxidative effect of flavonoids rich in the plant.

**CONCLUSION**

The present study showed that Methanolic extract of *Ficus religiosa* linn produce protective action against the hepatotoxicity induced by isoniazid+rifampicin and paracetamol. The hepatoprotective role of MEFR might be due to its chemical constituent like flavonoids and phenolic compound. Traditionally flavonoids produce antioxidant activity so this mechanism suggesting that the extract of plant may be useful to prevent the oxidative stress induced damage in liver. Hence MEFR may be act as prophylactic as well as curative drug in treating hepatic toxic conditions. Further studies needs to isolate the active constituents and also to evaluate the exact mechanism of action.
