SUMMARY

We demonstrate that GITR is predominantly expressed on human pMMR CRC- and CRLM-derived TIL. We show that GITR-mediated checkpoint stimulation ameliorates TIL functionality and anti-PD1-mediated TIL reinvigoration, thereby providing rationale for immunotherapies targeting GITR in pMMR CRC and CRLM patients.

BACKGROUND & AIMS: In contrast to mismatch repair deficient colorectal carcinoma (CRC), MMR proficient (pMMR) CRC does not respond to immune checkpoint blockade. We studied immune checkpoint stimulation via glucocorticoid-induced tumor necrosis factor receptor-related protein (GITR) on ex vivo functionality of human tumor-infiltrating lymphocytes (TIL) isolated from pMMR primary CRC and liver metastases (CRLM).

METHODS: Using lymphocytes from resected tumor, adjacent tissues, and peripheral blood mononuclear cells (PBMC) of 132 pMMR primary CRC or CRLM patients, we determined GITR expression and the in vitro T-cell agonistic activity of recombinant GITL ligation.

RESULTS: Here, we show that GITR was overexpressed on TIL when compared with other stimulatory immune checkpoints (4-1BB, OX40). Its expression was enhanced in TIL compared with PBMC and adjacent tissues. Among CD4⁺ TIL, GITR expression was primarily expressed by CD45RA⁻ FoxP3⁺ activated regulatory T cells. Within CD8⁺ TIL, GITR was predominantly expressed on functionally exhausted and putative tumor-reactive CD103⁺ CD39⁺ TIL. Strikingly, recombinant GITRL reinvigorated ex vivo TIL responses by significantly enhancing CD4⁺ and CD8⁺ TIL numbers. Dual treatment with GITRL and nivolumab (anti-PD1) enhanced CD8⁺ TIL expansion compared with GITRL monotherapy. Moreover, GITRL/
anti-PD1 dual therapy further improved anti-PD1-mediated reinvigoration of interferon gamma secretion by exhausted CD8 TIL from primary CRC.

**CONCLUSIONS:** GITR is overexpressed on CD4+ and CD8+ TIL from pMMR CRC and CRLM. Agonistic targeting of GITR enhances ex vivo human TIL functionality and may therefore be a promising approach for novel monotherapy or combined immunotherapies in primary pMMR CRC and CRLM. *(Cell Mol Gastroenterol Hepatol 2023;15:77–97; https://doi.org/10.1016/j.jcmgh.2022.09.007)*

**Keywords:** Colorectal carcinoma; Immune Checkpoint Stimulation; Liver metastasis; Microsatellite Stable; TNF Receptor Superfamily; Tumor-Infiltrating Lymphocytes.

Colorectal cancer (CRC) is the second and third most common cancer worldwide in women and men, respectively.1 In 2020, 1.9 million newly diagnosed patients and 935,000 disease-related deaths were reported, letting CRC account for 10% of total cancer incidence and mortality annually.1 Even though recent diagnostic and treatment regimens have enhanced overall survival rates significantly, there remains a need for further improvement.2 Extensive analyses on genomic, epigenomic, and transcriptomic CRC features have extended our understanding on CRC biology and its stromal-immune microenvironment, pleading for a more tailor-made, subtype-based therapeutic approach.3,4 Enhanced inflammatory stromal immune infiltration has been linked to a more favorable clinical outcome in early-stage CRC.5 High intratumoral and peritumoral CD8+ cytotoxic T lymphocyte (CTL) and CD4+ T helper 1 (Th1) content is limited to the hypermutated microsatellite instable (MSI) subtype of CRC.6 Recent clinical trials on programmed cell death 1 (PD1)-based immune checkpoint inhibition have confirmed survival benefit in these patients, exploiting the inflammatory immune phenotype, granting Food and Drug Administration approval for the treatment of metastatic mismatch repair–deficient and MSI-high (dMMR-MSI-H) CRC.6,7,9 In contrast, mismatch repair–proficient and MSI-low (pMMR-MSI-L) CRC, comprising 85% of the total CRC population, has hardly shown any response to immune checkpoint blockade (ICB).6,7,10 Its impaired clinical activity is hypothesized to be caused by poor immune cell infiltration, decreased inhibitory ligand expression, local immune suppression, and enhanced exhaustion of tumor-infiltrating CTL.3,11,12 Therefore, there is a need for effective immunotherapy that boosts the impaired tumor immune microenvironment in pMMR CRC.

Promoting anti-tumor immune responses via agonistic targeting of co-stimulatory receptors on tumor-infiltrating lymphocytes (TIL) is a promising alternative to current ICB therapies. In addition to T-cell receptor (TCR) signaling, co-stimulation is required to initiate effective T-cell activation, subset differentiation, effector function, and survival.13 Among co-stimulatory receptors, members of the tumor necrosis factor receptor superfamily (TNFRSF) (CD30, DR3, GITR, HVEM, OX-40, TNFR3, 4-1BB) have been widely studied for their application in anti-cancer immunotherapy.14,15 GITR is considered one of the most notable TNFRSF checkpoints because its activation has been shown to activate effector T cells, hamper regulatory T cell (Treg) functionality, and induce efficient anti-tumor responses in preclinical models using agonistic antibodies.16–22 Recent phase 1 clinical trials have reported manageable safety profiles for GITR targeting therapy among multiple advanced solid tumors; therefore, this approach may also be relevant for patients with pMMR CRC.24–26 Yet, expression and functionality of co-stimulatory checkpoint receptors including GITR on TIL isolated from CRC have not been elucidated.

In this study, we aimed to analyze the expression of TNFRSF members GITR, OX40, and 4-1BB on TIL in pMMR CRC and pMMR CRC-derived liver metastasis (CRLM) patients. Because GITR was expressed most prominently on CD4+ and CD8+ TILs, in functional assays we focused on co-stimulatory receptor targeting via agonistic GITR ligation in pMMR CRC and CRLM patients. We demonstrate that GITR is expressed by activated CD4+ and non-terminally exhausted CD8+ TIL. Moreover, GITR co-stimulation is found to be an effective immunomodulatory approach enhancing proliferation and function of TIL from pMMR CRC and CRLM patients. Last, GITR co-stimulation enhanced anti-PD1-mediated immune stimulation in pMMR CRC-derived TIL.

focused on CRC- and CRLM-derived CD4⁺ T cells to investigate TNFSRF member expression. Total CD45⁺ TIL fractions contained more CD4⁺ T cells compared with adjacent tissues. Compared with liver tissues, colorectal tissues demonstrated slightly higher frequencies of CD4⁺ T cells compared with adjacent tissues. In CRC and CRLM-derived TIL, GITR was expressed more prominently in CRC-derived aTreg and aTh compared with PBMC and adjacent tissues (Figure 1E).

We compared expression of GITR, 4-1BB, and OX40 on tumor-derived aTreg, aTh, and Th. In CRC, aTreg, aTh, and Th demonstrated enhanced GITR expression compared with 4-1BB and OX40 (Figure 2A). Moreover, GITR was expressed more prominently in CRC-derived aTreg and aTh compared with OX40 (Figure 2B). We conclude that high rates of co-expression among TNFSRF members were observed on all CD4⁺ TIL subsets, with GITR being expressed most prominently, especially in CRC.

Therefore, we focused further on GITR expression among CD4⁺ Th, aTh, and aTreg in TIL, adjacent tissues, and PBMC. In CRC and CRLM-derived TIL, GITR was expressed on Th (11.2% ± 1.3% and 5.8% ± 1.1%, respectively) and aTh (29.4% ± 2.4% and 16.9% ± 1.4%, respectively), whereas the highest expression was found on aTreg (54.5% ± 2.5% and 42.8% ± 2.5%, respectively) (Figure 2C and D). A similar trend was observed with regard to median fluorescent intensities (MFIs) of GITR (Figure 2C and D).

Compared with PBMC and adjacent tissues, GITR expression was significantly increased in all CD4⁺ TIL subsets. For CRC Th, expression was increased 0.7% ± 0.2% and 3.0% ± 1.2% vs 11.2% ± 1.3%, respectively; for aTh it was increased 2.5% ± 0.5% and 9.8% ± 2.2% vs 29.4% ± 2.4%, respectively; and for aTreg it was increased 5.1% ± 0.8% and 24.3% ± 2.8% vs 54.5% ± 2.5%, respectively (Figure 2E).

For CRLM Th, expression was increased 0.7% ± 0.2% and 1.4% ± 0.4% vs 5.8% ± 1.1%, respectively; for aTh it was increased 3.3% ± 0.6% and 6.3% ± 1.1% vs 16.9% ± 1.4%, respectively; and for aTreg it was increased 5.0% ± 0.9% and 20.7% ± 2.1% vs 42.8% ± 2.5%, respectively (Figure 2E). Importantly, we observed co-expression of GITR with proliferation and activation markers Ki67 or HLA-DR among all distinct CD4⁺ TIL subsets (Figure 3).

Taken together, we demonstrate that compared with adjacent tissues, expression of the co-stimulatory molecule GITR is increased most prominently of all TNFRSF members investigated on aTh and aTreg in TIL from pMMR CRC and CRLM patients and that its expression is associated with proliferation and activation markers.

GITR Delineates Activated CD103⁺ CD39⁺ CD8⁺ TIL From pMMR CRC and CRLM

Subsequently, we studied co-stimulatory molecule expression on cytotoxic CD8⁺ T cells from pMMR CRC and

CRLM patients. Compared with colorectal tissues, CRLM demonstrated higher frequencies of CD8$^+$ T cells among total CD45$^+$ T cells (Figure 4A). CD8$^+$ T cells were increased in total CD45$^+$ TIL fractions compared with adjacent tissues in CRC but not in CRLM.

Tumor-derived CD8$^+$ T cells demonstrated higher co-stimulatory receptor expression (GITR, 4-1BB, and/or OX40) compared with PBMC in CRC (Figure 4B). In CRLM, co-stimulatory receptor expression was enhanced on tumor-
derived CD8⁺ T cells compared with PBMC and adjacent tissues (Figure 4C).

From the TNFSF members analyzed in CRC, GITR was expressed at higher frequencies compared with 4-1BB and OX40 on CD8⁺ TIL (Figure 5A). On CRLM-derived CD8⁺ TIL, GITR and 4-1BB showed enhanced expression compared with OX40 (Figure 5B).

Compared with PBMC and adjacent tissues, GITR expression was increased on CD8⁺ TIL from CRC (9.7% ± 1.1% vs. 0.6% ± 0.1% and 3.6% ± 0.6%, respectively) and CRLM (8.4% ± 1.5% vs. 1.8% ± 0.4% and 1.6% ± 0.3%, respectively) (Figure 5C and D). Mean frequencies of GITR expression on CD8⁺ TIL were similar for CRC and CRLM (9.7% and 8.4%, respectively). GITR MFI of CD8⁺ T cells in CRC and CRLM was similar among all fractions (Figure 5C and D).

Comparison between GITR⁺ and GITR⁻ CD8⁺ TIL revealed co-expression of GITR with proliferation marker Ki67 on CD8⁺ TIL (Figure 5E). Recently, Duhen et al.²² have shown that co-expression of CD39 and CD103 identifies tumor-reactive CD8 T cells in human CRC tumors. In our cohort, we confirmed enrichment of CD39⁺ CD103⁺ (double positive) CD8⁺ T cells among TIL fractions compared with adjacent tissues and PBMC (data not shown). CRC- and CRLM-derived CD8⁺ TIL generally contained 47.5% and 41.1% of CD39⁺ CD103⁺ cells, respectively. Strikingly, CD39⁺ CD103⁺ CD8⁺ TIL appeared to be enriched for GITR (Figure 5F).

**GITR Expressing PD1hi CD8⁺ TIL Feature an Exhausted Phenotype With Enhanced Proliferative Capacity in pMMR CRC and CRLM**

Because GITR expression on CD8⁺ TIL appears to be linked to a more activated, potentially tumor-reactive phenotype, we aimed to analyze the functional state of GITR⁺ CD8⁺ TIL.

Although enhanced activation marker expression suggests increased functionality of GITR⁺ CD8⁺ TIL, upon ex vivo restimulation we observed that interferon gamma (IFN-γ) and tumor necrosis factor alpha (TNF-α) secretion by GITR⁺ CD8⁺ TIL were significantly impaired compared with the GITR⁻ counterpart, suggesting a more functionally exhausted state of the GITR⁺ population (Figure 6A).

Therefore, we correlated GITR expression with well-defined CD8⁺ T-cell exhaustion markers PD1 and lymphocyte-activation gene 3 (LAG3). Overall, patient-derived TIL from CRC and CRLM contained generally 9.9% and 11.5% PD1hi and 13.0% and 11.0% LAG3⁺ cells, respectively (Figure 6B). We could demonstrate that GITR⁺ CD8⁺ TIL were generally concentrated among the PD1hi and LAG3⁺ cell population (Figure 6C). GITR⁺ CD8⁺ cell frequencies correlated positively with both the frequency of PD1hi and LAG3⁺ TIL (R² = 0.86 and 0.75, respectively; Figure 6D). Furthermore, transcription factor TOX was demonstrated to be up-regulated by PD1hi CD8⁺ TIL independently of GITR expression (Figure 6E). However, remarkably, TCF1 expression was enhanced in PD1hi GITR⁺ CD8⁺ TIL compared with PD1hi GITR⁻ cells, and the former population showed significantly enhanced Ki67 expression (Figure 6F).

These data demonstrate that GITR is predominantly expressed by functionally impaired CD8⁺ TIL characterized by enhanced inhibitory receptor and TOX expression ex vivo. Nevertheless, GITR⁺ PD1hi CD8⁺ TIL differ from GITR⁻ PD1hi CD8⁺ TIL because they demonstrate an enhanced proliferative capacity based on enhanced Ki67 and TCF1 expression. Agonistic targeting of GITR might potentially functionally reinvigorate this cell population.

**GITR Ligation Enhances pMMR CRC- and CRLM-Derived CD4⁺/CD8⁺ TIL Expansion and Pro-inflammatory Cytokine Secretion**

The immune modulatory effect of GITR ligation on TIL was tested in vitro. Primary TIL were cultured in the presence of anti-CD3/-CD28 activation beads providing initial TCR and CD28 signaling, which is required for efficient GITR-mediated co-stimulation. After 8–10 days of in vitro culture, CD4⁺ and CD8⁺ TIL expansion was determined by ratiometric evaluation of cell numbers by flow cytometry using counting beads (Figure 7A).

Variable baseline proliferation rates of TIL were observed among individual patients, but overall co-culture in the presence of hexameric GITRL doubled the numbers of CD4⁺ and CD8⁺ pMMR CRC- and CRLM-derived TIL compared with TIL stimulated in the presence of αCD3/CD28 alone (Figure 7B–D). We could demonstrate a dose-dependent increase for both CD4⁺ and CD8⁺ TIL proliferation (Figure 7C). Moreover, proliferation marker Ki67 was significantly enhanced upon GITRL treatment for both TIL.
Figure 2. GITR is predominantly expressed on intratumoral CD4+ activated Th and Treg cells. (A and B) Frequencies of GITR, 4-1BB, and OX40 on aTreg, aTh, and Th in tumor. CRC are depicted in blue (n = 18), and CRLM are depicted in red (n = 9). (C and D) Frequencies and MFI of GITR on aTreg, aTh, and Th in tumor. CRC are depicted in blue (n = 42), and CRLM are depicted in red (n = 23). (E) Histogram and frequencies of GITR-positive cells among aTreg, aTh, and Th in tumor (T), adjacent tissues (A), and PBMC (P). CRC are depicted in blue (n = 40), and CRLM are depicted in red (n = 22). Friedman (A–D) or Kruskal-Wallis test (E) was applied to analyze differences between more than 2 different groups. *P ≤ .05, **P ≤ .01, ***P ≤ .001, ****P ≤ .0001. subsets (Figure 7E). Correlating with the ex vivo GITR expression data, CD4\(^+\) TIL demonstrated higher Ki67 frequencies compared with CD8\(^+\) TIL upon GITR ligation. Nevertheless, expansion rates did not significantly differ between both TIL subsets (data not shown).

To study how GITR ligation affects different CD4\(^+\) TIL subsets, we compared the expansion of FoxP3\(^-\) and FoxP3\(^+\) CD4\(^+\) TIL in vitro. Generally, after GITR ligation FoxP3\(^-\) CD4\(^+\) TIL demonstrated enhanced expansion compared with FoxP3\(^+\) TIL (Figure 8A). Furthermore, FoxP3 MFI declined upon GITR ligation, suggesting a reduced immune suppressive capacity, as was described previously in liver cancers (Figure 8B).\(^{21}\) To confirm the ability of CD4\(^+\) Th TIL to respond to GITR ligation independently of Treg, we cultured CD25-depleted TIL for 8–10 days. CD4\(^+\) TIL demonstrated similar expansion rates compared with controls in the presence or absence of CD25\(^+\) CD4\(^+\) Treg TIL, suggesting that the presence of aTreg within the TIL does not negatively impact the effect of GITR ligation on T-cell proliferation (Figure 8C).

To evaluate pro-inflammatory effector cytokine secretion by CD3⁺ TIL, after 8–10 days of in vitro culture with or without GITR ligation, total TIL were restimulated using PMA-ionomycin. Upon restimulation, CD3⁺ TIL that were treated with GITRL demonstrated increased frequencies of both IFN-γ⁺ and TNF-α⁺ cells compared with non-treated TIL (Figure 9A). These data were confirmed by the detection of elevated IFN-γ levels in the culture supernatants of

pMMR CRC and CRLM TIL that were treated with GITR ligation (Figure 9B). Furthermore, pro-inflammatory proteases granzyme A (GzmA), granzyme B (GzmB), and perforin were increased in response to GITRL in CRC-derived TIL cultures as well (Figure 9C).

Remarkably, GITR ligation not only skewed TIL to enhance pro-inflammatory cytokine secretion but also improved pro-inflammatory chemokine secretion. In CRC-derived TIL cultures, we detected enhanced CCL3, CCL4, CCL17, and CXCL9 levels (Figure 10A). CCL3, CCL4, CCL17, CXCL1, and CXCL5 levels showed a trend to increase among CRLM-derived cultures (Figure 10B).

Taked together, these data demonstrate that GITR ligation reinvigorates CRC- and CRLM-derived CD4+ and CD8+ TIL functionality, leading to enhanced pro-inflammatory cytokine or chemokine secretion.

**GITR Ligation Potentiates Immune Stimulation of Anti-PD1 in pMMR CRC-derived TIL**

So far, PD1 blockade monotherapy has not shown a clinical benefit in pMMR CRC and CRLM patients. Our data demonstrate that tumor-derived GITR+ CD8+ T cells were generally concentrated among the PD1hi CD8+ TIL. Therefore, we studied whether co-stimulatory checkpoint targeting via GITR ligation could enhance anti-PD1-mediated T-cell reinvigoration in vitro.

In the majority of patient-derived TIL, anti-PD1 monotherapy did not enhance TIL expansion or effector cytokine production (Figure 11). However, GITR co-stimulation in combination with PD1 blockade did enhance pMMR CRC-derived CD4+ and CD8+ expansion (Figure 11A and B). Conformably, proliferation marker Ki67 was significantly enhanced upon combination treatment for CD8+ TIL (Figure 11B). Ultimately, IFN-γ production in CD4+ and CD8+ TIL was enhanced upon PMA-ionomycin restimulation after in vitro culture with the combination regimen as well as TNF-α production in CD4+ TIL, indicating that GITR co-stimulation improves anti-PD1-mediated immune stimulation in pMMR CRC-derived TIL (Figure 11C and D).

**Discussion**

Whereas clinical trials on PD1-based immune checkpoint inhibition have shown great anti-tumor efficacy in dMMR (MSI-high) CRC, pMMR (MSI-low or microsatellite stable [MSS]) tumors that occur in the majority of CRC and CRLM patients do not respond well to ICB.14,37 Particularly, the implementation of co-stimulatory checkpoint targeting in anti-tumor immunotherapy is widely studied in preclinical and early clinical trials as a suitable alternative or supportive approach for ICB. Yet, the biological and clinical implications of these receptors in anti-tumor immunotherapy remain elusive. In this study, we aimed to comprehensively analyze the expression of TNFRSF members GITR, OX40, and 4-1BB on CD4+ and CD8+ TIL and to associate their expression to T-cell activation or exhaustion status in pMMR CRC and CRLM patients. Furthermore, we studied the impact of GITR co-stimulation on pMMR-CRC- and -CRLM-derived-TIL functions.

In a cohort of 132 patients with pMMR CRC or CRLM, we first demonstrated that GITR was expressed more prominently on tumor-derived TIL compared with OX40 and 4-1BB. Furthermore, GITR was predominantly co-expressed with OX40 and 4-1BB and compromised the vast majority of TIL expressing a TNFRSF member. GITR expression was enhanced on activated, proliferating CD4+ and CD8+ TIL. CD4+ aTh and aTreg displayed highest GITR expression compared with their counterparts in adjacent tissues and blood. Notably, GITR expression in CD8+ TIL delineated putative tumor reactive TIL.

To our knowledge, this is the first comprehensive report of GITR expression in human patient-derived pMMR CRC tissues. Co-stimulatory TNFRSF members have been described to be differentially expressed on TIL from different tumor types. Recently, Kim et al demonstrated enhanced 4-1BB expression on CD8+ TIL from hepatocellular carcinoma (HCC) compared with expression of various other TNFRSF members (eg, GITR, TNFR2, HVEM, DR3, OX40, CD30). Others have demonstrated varying levels of GITR expression in the tumor microenvironment (TME) from several solid tumors (non-small cell lung carcinoma, renal cell carcinoma, melanoma, and HCC). However, in all tumor types GITR expression was highest on CD4+ and CD4+ FoxP3+ TIL.34 We demonstrate that also in pMMR CRC and CRLM, compared with other TNFRSF members, GITR is prominently expressed by CD4+ TIL, co-expressed with proliferation and activation markers (Ki67 and HLA-DR, respectively), and enriched within the TME compared with adjacent tissues and blood.
Enhanced GITR expression was detected on CD4⁺ CD45RA⁻ FoxP3ʰⁱ aTreg and non-suppressive CD4⁺ CD45RA⁻ FoxP3ʰˡ aTh. Improved activation and anti-tumor immunity via GITR engagement in CD4⁺ TIL are described to be mediated either by CD4⁺ Treg depletion via Fcγ-receptor co-engagement on innate immune cells or CD4⁺ Treg
functionality impairment via lineage destabilization.\textsuperscript{22,35,36} We have confirmed previously that co-stimulation via GITR could alleviate Treg-mediated immune suppression, restoring proliferative capacity and cytokine production of non-Treg (CD4\textsuperscript{+}CD25\textsuperscript{-}) TIL from primary and secondary liver tumors.\textsuperscript{37} Nevertheless, multiple studies have shown a direct stimulatory effect of GITR ligation on effector TIL as well.\textsuperscript{20,22,38,39} Moreover, hexameric GITR ligation (GITRL) in human naive PBMC was shown to induce CD4\textsuperscript{+} T-cell proliferation in the absence of Treg.\textsuperscript{40} In CRC, TME-residing aT cells have been shown to correlate with improved survival rates because they produce pro-inflammatory cytokines and harbor anti-tumor immunity.\textsuperscript{31,41} Although on the basis of our in vitro functional polyclonal assay we cannot distinguish between any direct or indirect effects on CD4\textsuperscript{+} (FoxP3\textsuperscript{+}) or CD8\textsuperscript{+} TIL, these findings by us and others suggest that immunotherapeutic targeting of GITR may stimulate the local immune response within the CRC-/CRLM-related TME through affecting both Treg and aT cell function.

In CRC, Duhen et al\textsuperscript{32} and Simoni et al\textsuperscript{42} have demonstrated that CD103\textsuperscript{+}CD39\textsuperscript{+}CD8\textsuperscript{+} TIL are enriched by tumor-reactive T cells. Here, we confirmed enrichment of CD103 and CD39 co-expression on CD8\textsuperscript{+} T cells in TIL compared with adjacent tissues and blood (data not shown). Interestingly, GITR expression was highest on CD103\textsuperscript{+}CD39\textsuperscript{+}CD8\textsuperscript{+} T cells, suggesting that tumor-reactive CD8\textsuperscript{+} T cells within the TME display GITR expression. Furthermore, enhanced expression of Ki67, HLA-DR, and perforin illustrates the pro-inflammatory state of these putative tumor reactive GITR\textsuperscript{+} CD8\textsuperscript{+} TIL. Yet, ex vivo CD8\textsuperscript{+} TIL stimulation revealed impaired effector cytokine secretion in GITR\textsuperscript{+} cells compared with GITR\textsuperscript{-} TIL, suggesting the former to be functionally impaired. Functional exhaustion of these cells might be caused by potential chronic T-cell receptor stimulation of CD103\textsuperscript{+}CD39\textsuperscript{+}CD8\textsuperscript{+} TIL in the TME.\textsuperscript{4,13} In support of this hypothesis, we observed enrichment of GITR among PD1\textsuperscript{hi} and LAG3\textsuperscript{+} CD8\textsuperscript{+} TIL. Interestingly, although there was enhanced transcription factor TOX expression in PD1\textsuperscript{hi} GITR\textsuperscript{-} and GITR\textsuperscript{+} CD8\textsuperscript{+} TIL, the latter showed enhanced TCF1 and Ki67 expression compared with PD1\textsuperscript{hi} GITR\textsuperscript{-} CD8\textsuperscript{+} TIL. Therefore, GITR seems to delineate PD1\textsuperscript{hi} CD8\textsuperscript{+} TIL into cells that demonstrate some similarity to exhausted T (Tex) precursor cells. In recent preclinical cancer models, these Tex precursor cells have been shown to be a crucial source for providing a robust response to ICB, suggesting that these cells may be eligible for GITR-mediated reactivation as well.\textsuperscript{44,45}

Whereas TNFRSF co-stimulation was thought to affect CD8\textsuperscript{+} TIL indirectly via its selective effect on CD4\textsuperscript{+} TIL, direct effects of GITRL on CD8\textsuperscript{+} TIL have been described.\textsuperscript{25,28} We performed polyclonal functional assays testing the ability of GITR to stimulate tumor-derived CD4\textsuperscript{+} and CD8\textsuperscript{+} TIL function ex vivo. We demonstrated enhanced Ki67 expression and expansion of CD4\textsuperscript{+} and CD8\textsuperscript{+} TIL from pMMR CRC and CRLM. In addition, tumor-derived T cells that were treated with GITRL demonstrated increased frequencies of both IFN-\gamma\textsuperscript{+} and TNF-\alpha\textsuperscript{+} cells and enhanced secretion of pro-inflammatory proteases and chemokines (e.g., CCL3, CCL4, CXCL9), potentially driving immune cells attraction and activation in the TME in vivo.\textsuperscript{46}

In mice, dual therapy of GITR co-stimulation and PD1 blockade was shown to enhance effector T-cell function synergistically by restoring the balance of key homeostatic regulators CD226 and T-cell immunoreceptor with Ig and ITIM domains.\textsuperscript{28} Moreover, it has been shown recently that the anti-GITR/anti-PD1 combination could restore the effector T-cell:Treg ratio, resulting in enhanced anti-tumor immunity.\textsuperscript{25,39} In concordance with clinical studies, our data indicate that anti-PD1 monotherapy hardly stimulates the activity of tumor-derived TIL from pMMR CRC in vitro. However, the combination regimen of anti-PD1 with GITRL led to significant functional T-cell reinvigoration. Because high GITR expression is mostly restricted to the tumor site, which potentially limits systemic adverse events of GITR targeting, in our opinion GITR represents an attractive target for therapeutic immunomodulation alone or in combination with ICB in these pMMR patients. Although treatment with anti-GITR antibodies had been shown to cause toxicity upon repeated administration in preclinical animal models, recently it has been shown that a newly developed fully human agonistic GITR immunoglobulin G1 monoclonal antibody in combination with nivolumab demonstrated an

![Figure 6](https://example.com/figure6.png)

**Figure 6. (See previous page).** GITR is up-regulated on PD1\textsuperscript{hi} CD8\textsuperscript{+} TIL featuring a (pre-)exhausted phenotype. TIL were isolated from tumor tissues using enzymatic digestion and subsequent Ficoll density gradient centrifugation. Ex vivo function and phenotype of TIL were analyzed using flow cytometry with or without in vitro stimulation. (A) Frequencies of IFN-\gamma\textsuperscript{+} and TNF-\alpha\textsuperscript{+} positive cells in GITR\textsuperscript{-} and GITR\textsuperscript{+} among CD8\textsuperscript{+} T cells in tumor after 5 hours of PMA/ionomycin stimulation (n = 8). CRC are depicted in blue, and CRLM are depicted in red. (B) Frequencies of PD1\textsuperscript{+}, PD1\textsuperscript{int}, or PD1\textsuperscript{hi} and LAG3\textsuperscript{-} or LAG3\textsuperscript{+} among CD8\textsuperscript{+} T cells in tumor. Blue and red bars represent CRC- and CRLM-derived TIL, respectively. (C) Gating strategy and frequencies of GITR, PD1, and LAG3 among CD8\textsuperscript{+} T cells in tumor. Frequencies of GITR among PD1\textsuperscript{+}, PD1\textsuperscript{int}, or PD1\textsuperscript{hi} and LAG3\textsuperscript{-} or LAG3\textsuperscript{+} CD8\textsuperscript{+} T cells in tumor. CRC are depicted in blue (n = 26), and CRLM are depicted in red (n = 13). (D) Correlation of frequencies of GITR-positive cells to frequencies of PD1\textsuperscript{+} or LAG3\textsuperscript{+} cells among CD8\textsuperscript{+} T cells in tumor. Blue and red dots represent individual CRC (n = 26 and n = 14, respectively) and CRLM (n = 13 and n = 8, respectively) patients. (E) Histogram and MFI of transcription factor TOX on PD1\textsuperscript{+}, PD1\textsuperscript{int}, GITR\textsuperscript{-} PD1\textsuperscript{+}, or GITR\textsuperscript{+} PD1\textsuperscript{hi} CD8\textsuperscript{+} T cells in tumor (n = 7). (F) Histogram and MFI of TCF1 on GITR\textsuperscript{-} PD1\textsuperscript{hi} or GITR\textsuperscript{+} PD1\textsuperscript{hi} CD8\textsuperscript{+} T cells in tumor (n = 8). Histogram and MFI of proliferation marker Ki67 on GITR\textsuperscript{-} PD1\textsuperscript{hi} or GITR\textsuperscript{+} PD1\textsuperscript{hi} CD8\textsuperscript{+} T cells in tumor (n = 14). CRC are depicted in blue, and CRLM are depicted in red. Wilcoxon matched test (A and F) was used to analyze differences between 2 paired groups. Friedman test (C and D) was used to analyze differences between more than 2 different groups. Correlation analysis was performed according to Spearman. **P \leq .01, ***P \leq .001, ****P \leq .0001. acceptable safety profile in patients with advanced solid tumors.26,47 In humans, GITR monoclonal antibodies have been shown to reduce circulating and intratumoral Treg.25 Yet, efficient direct T-cell activation via TNFR requires receptor clustering to induce optimal downstream signal transduction.19 In our study, GITR oligomerization is facilitated using a hexameric GITRL. Other strategies to induce receptor multimerization are Fc-engineering or the construction of bi-specific antibodies.48,49 Chan et al49 have recently shown the great potential of combining immune checkpoint stimulation (ICS) and ICB using an anti-PD-1-GITR-L bispecific. In particular, the approach of bispecific antibodies deserves great attention for development of future clinical trials on ICS because these constructs not only drive receptor multimerization but also directly GITR-mediated activation to tumor reactive PD-1 expressing cells only.

The strength of our study is the use of human patient-derived TIL, but it entails some limitations as well.3 Because all patients underwent surgical resection, our study cohort does not comprise the full spectrum of the CRC and CRLM patient population. Currently, the efficacy of immunotherapy has been mostly studied in advanced therapy resistant tumors. Nevertheless, the (neo)adjuvant application of immunotherapy in early or intermediate stage disease is being studied more and more frequently.7 Some patients from our CRC and CRLM cohort have undergone systemic therapy before resection. Therapeutic regimen might have varied among individual patients, potentially changing the composition of the TME. To exclude any direct effects of neoadjuvant therapy on the TME, minimum time before surgery was set at 4 weeks.3 TIL numbers isolated from individual patient tissues were highly variable. Therefore, phenotype analysis and in vitro functional assays could not be performed in all patients.

In summary, we conclude that GITR is enriched in CD4+ aTh and aTreg TIL as well as in PD1hi CD8+ TIL. Furthermore, GITRL enhances pMMR CRC- and CRLM-derived human TIL functionality ex vivo. Our study provides compelling preclinical data that support agonistic targeting of GITR as part of a new immunotherapeutic approach for pMMR CRC and CRLM patients.

**Methods**

**Patient Selection**

Patients (age >18 years) undergoing surgical resection between July 2016 and November 2021 for either primary CRC (stage 1–3) or CRLM were included from 3 different hospitals. Patients having received (any) neoadjuvant treatment or immunosuppressive therapy <4 weeks and <3 months before surgical resection were excluded from our study. Peripheral blood was drawn on the day of the surgical resection before surgery. In accordance with the pathologists, fresh samples of tumor and adjacent tumor-free tissues (>10 cm and >2 cm distant of the tumor for primary CRC and liver metastasis, respectively) were obtained and processed within 24 hours.
repair gene-related proteins: MLH1, PMS2, MSH2, and MSH6. Patient data were retrieved from electronic medical records. All study procedures were approved by the local ethics committee (NL58534.078.16; NL47888.041.14). Patients had given informed consent for tissue and blood donation as well as usage of personal data.

**Cell Preparation**

PBMC were isolated by Ficoll density gradient centrifugation. Mononuclear single cell suspensions from tumor and adjacent tissues were obtained by enzymatic tissue digestion. Adjacent colon tissues were cut and stirred in the presence of EDTA (10% fetal calf serum, 15 mmol/L HEPES, 1 mmol/L EDTA in phosphate-buffered saline) 4 times for 15 minutes at 37°C. Subsequently, adjacent colon as well as cut primary CRC tissues were digested in the presence of 400 U/mL collagenase type VIII (Sigma-Aldrich, St Louis, MO) and 0.2 mg/mL DNAse I (Sigma-Aldrich) in Hanks balanced salt solution for 30–60 minutes at 37°C with interrupted gently swirling. CRLM and adjacent liver tissues were cut into small pieces and then digested with 0.2 mg/mL DNAse I (Sigma-Aldrich) and 0.125 mg/mL collagenase type IV (Sigma-Aldrich) for 40 minutes at 37°C with

**Figure 9. GITR ligation increases CD3⁺ TIL pro-inflammatory cytokine secretion.** TIL were isolated from tumor tissues using enzymatic digestion and subsequent Ficoll density gradient centrifugation. TIL were stimulated using CD3/CD28 stimulation beads in absence (ctrl) or presence of hexameric GITR ligand (GITRL 1 μg/mL + anti-HA 2.5 μg/mL). After 8 days, supernatants were analyzed for soluble factors, and TIL were phenotyped after PMA/ionomycin restimulation. (A) Flow cytometric gating strategy and relative frequencies of IFN-γ and TNF-α producing pMMR CRC-derived CD3⁺ TIL upon PMA/ionomycin restimulation after GITR ligation compared with control conditions (n = 11). (B) Concentration of secreted IFN-γ defined as fold increase over control conditions. CRC are depicted in blue (n = 18), and CRLM are depicted in red (n = 4). (C) Concentration of secreted cytokines defined as fold increase over control conditions. CRC are depicted in blue (n = 6). Wilcoxon matched test was used to analyze differences between 2 paired culture conditions. *P ≤ .05. Boxes and whiskers represent mean and 95% confidence interval. CRC, primary colorectal cancer; CRLM, liver metastasis; Ctrl, control; IFN-γ, interferon gamma; TIL, tumor-infiltrating lymphocyte; TNF-α, tumor necrosis factor alpha.
interrupted gently swirling. Cell suspensions were filtered through 70-μm pore cell strainers (BD Biosciences, San Diego, CA), and mononuclear leukocytes were obtained by Ficoll density gradient centrifugation. Mononuclear cell viability, CD45/CD3 purities, and cell numbers were determined using flow cytometry (MACS Quant; Miltenyi Biotec, Bergisch Gladbach, Germany). A minimum of 100,000 total CD3+ TIL/1 g tissue was set for study inclusion.

**Flow Cytometric Analysis**

Freshly isolated PBMC, tumor-infiltrating lymphocytes, and tissue-infiltrating lymphocytes were analyzed for the expression of specific surface and intracellular markers using monoclonal antibodies (Table 3). Nonviable cells were excluded by labeling with Fixable Viability Dye Efluor 506 (eBioscience, Vienna, Austria). Cell surface staining with fluorochrome-conjugated antibodies was performed in the dark at 4°C for 30 minutes, after which cells were fixed, permeabilized using the FoxP3 staining buffer kit (eBioscience), and stained for intracellular antigens. Cells were measured using a FACSComp II, FACSArray SORP II, or FACSymphony flow cytometer (BD Biosciences) and analyzed using FlowJo software version V10 (BD Biosciences). Appropriate isotype control antibodies were used for gating purposes (Table 3).

**Ex Vivo Polyclonal T-Cell Activation Assay**

Isolated total TIL were either used directly for in vitro culture or purified using Magnetic Cell Separation. CD25-depleted TIL fractions were obtained by negatively selecting CD25+ TIL with human CD25 MicroBeads II (130-0920983; Miltenyi Biotec). Efficiency of Magnetic Cell Separation was set to a minimum of 90% purity of FoxP3- within CD25- TIL fractions. TIL cultures were performed in RPMI 1640 (Lonza, Breda, the Netherlands) supplemented with 10% human AB serum (Sigma-Aldrich), 2 mmol/L L-glutamine (Invitrogen, Waltham, MA), 50 mmol/L Hepes Buffer (Lonza), 1% penicillin-streptomycin (Gibco-Life Technologies, Oslo, Norway), 5 mmol/L sodium pyruvate (Gibco-Life Technologies), and 1% minimum essential medium non-essential amino acids (complete medium) at 37°C and 5% CO2. TIL were cultured in a 96-well round-bottom culture plate (0.5 × 10^6 CD45+ cells/well) in the presence of anti-human anti-CD3/CD28 Dynabeads (cell:bead ratio 100:1; Gibco-Life Technologies). Experiments in the range of >15% baseline Ki67 expression on T cells after day 8-9 of culture were included unless mentioned otherwise. Overall, suboptimal CD3/CD28-mediated pre-stimulation could be reached in approximately 85% of all vitro TIL cultures. For indicated experiments, cells were treated with 1 µg/mL azide-free and low endotoxin soluble GITRL (R&D Systems, Minneapolis, MN) crosslinked with 2.5 µg/mL anti-HA antibody (R&D Systems) alone or in combination with 10 µg/mL humanized immunoglobulin G4 blocking anti-PD1 antibody (Nivolumab; Bristol-Myers Squibb, New York, NY) or the corresponding isotype control antibody (hIgG4, clone QA16A15; Biolegend, San Diego, CA). After 8–9 days, culture supernatants were collected and quantified for cytokines/chemokines using LegendPlex Human CD8/NK Panel and/or Human Pro-Inflammatory Cytokine Panel.
Chemokine Panel (740267 and 740985, respectively; Biolegend). For indicated experiments, cells were restimulated (on day 0 and day 8/9) using PMA (40 ng/mL; Sigma-Aldrich), ionomycin (1 μg/mL; Sigma-Aldrich), and Monensin (1000X; eBioscience). T-cell expansion was determined on the basis of ratiometric determination of absolute cell counts using counting beads (01-1234-42; Thermo Fisher Scientific, Waltham, MA).

Figure 11. (See previous page). GITR ligation further enhances anti-PD-1-mediated reinvigoration of CD4+ and CD8+ TIL. TIL were isolated from tumor tissues using enzymatic digestion and subsequent Ficoll density gradient centrifugation. TIL were stimulated using CD3/CD28 stimulation beads in presence of isotype antibodies (iso IgG4), anti-PD1 blocking antibodies (× PD1), anti-PD1 blocking antibodies in combination with GITRL (× PD1 + GITRL), or GITRL (GITRL). After 8 days, TIL were phenotyped directly or after PMA/ionomycin restimulation. TIL expansion and cytokine secretion were measured and defined as fold increase over isotype control conditions (proliferation and stimulation index, respectively). (A) pMMR CRC-derived CD4+ TIL Ki67 expression and expansion upon iso IgG4, αPD1, αPD1 + GITRL, and GITRL (n = 12). (B) pMMR CRC-derived CD8+ TIL Ki67 expression and expansion upon iso IgG4, × PD1, × PD1 + GITRL, and GITRL (n = 12). (C) Flow cytometric gating strategy and relative frequencies of IFN-γ and TNF-α producing pMMR CRC-derived CD4+ TIL upon PMA/ionomycin restimulation after × PD1, × PD1 + GITRL, and GITRL compared with isotype control conditions (n = 10). (D) Flow cytometric gating strategy and relative frequencies of IFN-γ and TNF-α producing pMMR CRC-derived CD8+ TIL upon PMA/ionomycin restimulation after × PD1, × PD1 + GITRL, and GITRL compared with isotype control conditions (n = 10). Friedman (A–D) was applied to analyze differences between more than 2 different groups. *P ≤ 0.05, **P ≤ 0.01, ***P ≤ 0.001, ****P ≤ 0.0001. Boxes and whiskers represent mean and 95% confidence interval. CRC, primary colorectal cancer; IFN-γ, interferon gamma; iso IgG4, isotype control; PI, proliferation index; SI, stimulation index; TIL, tumor-infiltrating lymphocyte; TNF-α, tumor necrosis factor alpha.
Statistical Analysis

Statistical analyses were performed using GraphPad Prism software version 9.0 (GraphPad, La Jolla, CA). A Wilcoxon matched test was used to analyze differences between 2 paired groups of data. Either a Friedman or a Kruskal-Wallis test was applied to analyze differences between more than 2 different groups. Correlation analysis was performed according to Spearman. A P value lower than .05 was considered statistically significant (*P ≤ .05, **P ≤ .01, ***P ≤ .001, ****P ≤ .0001). All authors had access to the study data and had reviewed and approved the final manuscript.
