Abstract. The well-studied semigroup $Sg(A) = \{ b : b = Ax, x \in \mathbb{Z}^n, x \geq 0 \}$ can be stratified by the sizes of the polyhedral fibers $IP_A(b) = \{ x : Ax = b, x \geq 0, x \in \mathbb{Z}^n \}$. The key theme of this paper is a structure theory that characterizes precisely the set $Sg_{\geq k}(A)$ of all vectors $b \in Sg(A)$ such that their fiber $IP_A(b)$ has at least $k$ solutions. We demonstrate that this set is finitely generated, a union of translated copies of a semigroup which can be computed explicitly via Hilbert bases computations. Related results can be derived for those right-hand-side vectors $b$ for which $IP_A(b)$ has exactly $k$ solutions or fewer than $k$ solutions. As a consequence, one can identify all right-hand-side vectors that have at least $k$ solutions.

Using this tool we prove that for fixed $n, k$ the $k$-Frobenius number can be computed in polynomial time, generalizing a well-known result of R. Kannan.

Keywords: Lattice points in polyhedra, Hilbert bases, combinatorial commutative algebra, affine semigroups, Frobenius numbers

1 Introduction

An affine semigroup is a semigroup (always containing a zero element) which is finitely generated and can be embedded in $\mathbb{Z}^n$ for some $n$. We study here a special kind of affine semigroups that appears in many interesting problems in combinatorics, commutative algebra, and number theory and that can be described in very explicit terms. Given an integer matrix $A \in \mathbb{Z}^{d \times n}$ and a vector $b \in \mathbb{Z}^d$, we study the semigroup $Sg(A) = \{ b : b = Ax, x \in \mathbb{Z}^n, x \geq 0 \}$. Geometrically it can be described as some of the lattice points inside the convex polyhedral cone $cone(A)$ of non-negative linear combinations of the columns of $A$. It is well-known that $Sg(A) \subset cone(A) \cap \mathbb{Z}^n$, but the equality is not always true. It is also well-known that $cone(A) \cap \mathbb{Z}^n$ is a finitely generated semigroup, this time with generators given by the Hilbert bases of $cone(A)$ [31][40]. The study of the difference between $Sg(A)$ and $cone(A) \cap \mathbb{Z}^n$ is quite interesting (e.g., has been part of many papers in commutative algebra about semigroups and their rings. See [9][19][23][44] and the references therein). Practically speaking, membership of $b$ in the semigroup $Sg(A)$ reduces to the challenge, given a vector $b$, to find whether the linear Diophantine system

$$Ax = b, \quad x \geq 0, \quad x \in \mathbb{Z}^n,$$

has a solution or not. We will denote the problem [1] by $IP_A(b)$. Geometrically, $IP_A(b)$ asks whether there is at least one lattice point inside the parametric polyhedron $P_A(b) = \{ x : Ax = b, x \geq 0 \}$. 

arXiv:1409.5259v1 [math.CO] 18 Sep 2014
Now, for a given integer \( k \) there are three natural interesting variations of the classical feasibility problem above that in a natural way measure the number of solutions of \( IP_A(b) \):

- Are there at least \( k \) distinct solutions for \( IP_A(b) \)? If yes, we say that the problem is \( \geq k \)-feasible.
- Are there exactly \( k \) distinct solutions for \( IP_A(b) \)? If yes, we say that the problem is \( = k \)-feasible.
- Are there less than \( k \) distinct solutions for \( IP_A(b) \)? If yes, we say that the problem is \( < k \)-feasible.

We call these three problems, the fundamental problems of \( k \)-feasibility. Given the integer \( k \) one can decompose \( \text{Sg}(A) \) taking into account the number of solutions for \( IP_A(b) \). The original feasibility problem is just the problem of deciding whether \( IP_A(b) \) is \( \geq 1 \)-feasible. This shows directly that \( k \)-feasibility problems are NP-hard in complexity. Recently Eisenbrand and Hähle [27] showed that the related problem of finding the right-hand-side vector \( b \) that maximizes the number of lattice points solutions, when \( b \) is restricted to take values in a polyhedron, is NP-hard.

This paper investigates the question of, given an integral matrix \( A \), determining for which right-hand-side vectors \( b \) are the problems \( IP_A(b) \) \( \geq k \)-feasible, \( = k \)-feasible, or \( < k \)-feasible. In what follows we say that \( b \) is \( \geq k \)-feasible, or respectively, \( = k \)-feasible or \( < k \)-feasible if the corresponding \( IP_A(b) \) is. The first part of this paper is about a decomposition of the semigroup \( \text{Sg}(A) \) into translated semigroups that group together all elements \( b \in \text{Sg}(A) \) that are \( \geq k \)-feasible (similarly for the other cases). The second part is about the theoretical and practical complexity of algorithms for finding such decomposition of \( \text{Sg}(A) \) in practice. A key application is the study of the \( k \)-Frobenius number, a number of interest in combinatorial number theory.

The theory of \( k \)-feasibility is useful in applications where a given number of solutions \( k \) needs to be achieved to consider the problem solved or where one cannot allow too many solutions. Naturally \( k \)-feasibility problems have interesting applications in combinatorics and statistics: Consider first the widely popular recreational puzzle sudoku, each instance can be thought of as an integer linear program where the hints provided in some of the entries are the given right-hand-sides of the problem. Of course in that case newspapers wish to give readers a puzzle where the solution is unique (\( k = 1 \)). It is not difficult to see that this is a special case of a \( 3 \)-dimensional transportation problem that is, the question to decide whether the set of \( \text{integer} \) feasible solutions of the \( r \times s \times t \)-transportation problem

\[
\begin{align*}
\left\{ x \in \mathbb{Z}^{rs} : & r \sum_{i=1}^{r} x_{ijk} = u_{jk}, \sum_{j=1}^{s} x_{ijk} = v_{ik}, \sum_{k=1}^{t} x_{ijk} = w_{ij}, x_{ijk} \geq 0 \right\}
\end{align*}
\]

has a unique solution given right-hand sides \( u, v, w \). Another application of \( k \)-feasibility appears in statistics, concretely in application in the data security problem of \( \text{multi-way contingency tables} \), because when the number of solutions is small, e.g. unique, the margins of the statistical table may disclose personal information which is illegal [25]. Polyhedra with fixed number of (interior) lattice points play a role in many areas of pure mathematics including representation theory, algebraic geometry and combinatorial geometry. Indeed, there has been a lot of work, going back to classical results of Minkowski and van der Corput, to show that the volume of a lattice polytope \( P \) with \( k = \text{card}(\mathbb{Z}^n \cap \text{int } P) \geq 1 \) is bounded above by a constant that only depends in \( n \) and \( k \) (see e.g., [33]). Similarly, the supremum of the possible number of points of \( \mathbb{Z}^n \) in a lattice polytope in \( \mathbb{R}^n \) containing precisely \( k \) points of \( \mathbb{Z}^n \) in its interior, can be bounded by a constant that only depends in \( n \) and \( k \). Such results play an important role in the theory of toric varieties and the structure of lattice polyhedra (see e.g., [29,19,44] and the references therein). The \( k \)-feasibility problems also relate to the growth of the values of Littlewood-Richardson coefficients through the polyhedral interpretations of those numbers (see [35] and its references).
Finally, our work is a generalization of a classical problem in combinatorial number theory. Let \( a \) be a positive integral \( n \)-dimensional primitive vector, i.e., \( a = (a_1, \ldots, a_n)^T \in \mathbb{Z}_{\geq 0}^n \) with \( \gcd(a_1, \ldots, a_n) = 1 \). For a positive integer \( k \) the \( k \)-Frobenius number \( F_k(a) \) is the largest number which cannot be represented in at least \( k \) different ways as a non-negative integral combination of the \( a_i \)’s. Thus, putting \( A = a^T \),

\[
F_k(a) = \max \{ b \in \mathbb{Z} : IP_A(b) \text{ is } < k\text{-feasible} \}.
\] (2)

When \( k = 1 \) this has been studied by a large number of authors and both the structure and algorithmic properties are well-understood. Computing \( F_1(a) \) when \( n \) is not fixed is an NP-hard problem (Ramirez Alfonsin [38]). On the other hand, for any fixed \( n \) the classical Frobenius number can be found in polynomial time by sophisticated deep algorithms due to Kannan [32] and later Barvinok and Woods [13]. The general problem of finding \( F_1(a) \) has been traditionally referred to as the Frobenius problem. There is a rich literature on the various aspects of this question. For a comprehensive and extensive survey we refer the reader to the book of Ramirez Alfonsin [39]. The \( k \)-feasibility generalization of the Frobenius number was introduced and studied by Beck and Robins in [16]. They gave formulas for \( n = 2 \) of the \( k \)-Frobenius number, but for general \( n \) and \( k \) only bounds on the \( k \)-Frobenius number \( F_k(a) \) are available (see [3], [6] and [28] for prior work).

Our Results

This paper has six contributions to the study of \( k \)-feasibility for the semigroup \( Sg(A) \), and the associated polyhedra. Throughout the paper we assume that the cone \( \text{cone}(A) \) is pointed. The six contributions guide the structure of this paper:

1. First, we prove a structural result that implies that the set \( Sg_{\geq k}(A) \) of \( b \)'s inside the semigroup \( Sg(A) \) that provide \( \geq k \)-feasible fibers \( IP_A(b) \) is finitely generated.

Let \( Sg_{\geq k}(A) \) (respectively \( Sg_{\leq k}(A) \) and \( Sg_{< k}(A) \)) be the set of right-hand side vectors \( b \in \text{cone}(A) \cap \mathbb{Z}^d \) that make \( IP_A(b) \geq k \)-feasible (respectively \( = k \)-feasible, \( < k \)-feasible). Note that \( Sg_{\geq k}(A) \) is equal to \( Sg(A) \), the semigroup generated by the column vectors of the matrix \( A \).

Our first structural theorem gives an algebraic description of the sets \( Sg_{\geq k}(A) \) and \( Sg_{< k}(A) \).

Let \( e_1, \ldots, e_n \) be the standard basis vectors in \( \mathbb{Z}_{\geq 0}^n \). We define the coordinate subspace of \( \mathbb{Z}_{\geq 0}^n \) of dimension \( r \geq 1 \) determined by \( e_{i_1}, \ldots, e_{i_r} \), with \( i_1 < \cdots < i_r \) as the set \( \{ e_{i_1}z_1 + \cdots + e_{i_r}z_r : z_j \in \mathbb{Z}_{\geq 0} \text{ for } 1 \leq j \leq r \} \).

By the 0-dimensional coordinate subspace of \( \mathbb{Z}_{\geq 0}^n \) we understand the origin \( 0 \in \mathbb{Z}_{\geq 0}^n \).

**Theorem 1.** (i) There exists a monomial ideal \( I^k(A) \subset \mathbb{Q}[x_1, \ldots, x_n] \) such that

\[
Sg_{\geq k}(A) = \{ A\lambda : \lambda \in E^k(A) \},
\] (3)

where \( E^k(A) \) is the set of exponents of monomials in \( I^k(A) \).

(ii) The set \( Sg_{< k}(A) \) can be written as a finite union of translates of the sets \( \{ A\lambda : \lambda \in S \} \), where \( S \) is a coordinate subspace of \( \mathbb{Z}_{\geq 0}^n \).

By the Gordan-Dickson lemma, the ideal \( I^k(A) \) is finitely generated, thus one can conclude

**Corollary 1.** \( Sg_{\geq k}(A) \) is a finite union of translated copies of the semigroup \( AZ_{\geq 0}^n \).

The proof of Theorem 1 relies on some basic facts on lattice points when we think of them as generators of monomial ideals. The basic tool is a characterization of the complement of a monomial ideal (see [21]). Some of the arguments are of interest for the study of affine semigroups and toric varieties [1844].
Theorem 1 extends the earlier decomposition theorem of Hemmecke, Takemura and Yoshida [30] for $k = 1$. They investigated the semigroup $S_g(A)$ and the integral vectors that are not in the semigroup, but still lie within the cone $cone(A)$ generated by the columns of $A$. Those authors studied $Q_{sat} = cone(A) \cap lattice(A)$, where $lattice(A)$ is the lattice generated by the columns of $A$. They called $H = Q_{sat} \setminus S_g(A)$ the set of holes of $S_g(A)$. The set of holes $H$ may be finite or infinite, but their main result is to give a finite description of the holes as a finitely-generated set. Our Theorem 1 was inspired by theirs. The elements of the set $S_{g<k}(A)$ can be viewed as $k$-holes (in the context of numeric semigroups and the Frobenius number, 1-holes have also been called gaps, see [37]), namely those right hand-sides $b$ for which $Ax = b$ has less than $k$ non-negative integral solutions. Section 2 gives a proof of Theorem 1 that relies on basic commutative algebra.

Second, although traditionally the Frobenius problem has been studied for $1 \times n$ matrices, in Sections 3-5 we discuss $F_k(A)$, a generalization of $k$-Frobenius number, but this time applicable to all matrices. We explain the meaning of this generalized $k$-Frobenius number to the structure of the set $S_{g\geq k}(A)$ when seen far away from the origin moving toward asymptotic directions inside the cone $A$. Essentially, under some natural assumptions for the matrix $A$, the set $S_{g\geq k}(A)$ can be decomposed into the set of all integer points in the interior of a certain translated cone and a smaller complex complementary set. We discuss the location of such a cone along a given direction $c$ in the interior of cone($A$). The key goal of Sections 3-5 is to derive the lower and upper bounds for $F_k(A)$. Based on the results obtained in [4], [6] we show that $F_k(A)$ is bounded from above in terms of $\det(AA^T)$ and $k$.

**Theorem 2.** Let $A$ be a matrix in $\mathbb{Z}^{d \times n}$, $1 \leq d < n$, satisfying

i) $gcd(\det(A_{I_d}) : A_{I_d}$ is a $d \times d$ minor of $A) = 1$,

ii) $\{ x \in \mathbb{R}_{\geq 0}^n : Ax = 0 \} = \{ 0 \}$.

Then the $k$-Frobenius number associated with $A$ satisfies the inequality

$$F_k(A) \leq \frac{n - d}{2(n - d + 1)^{1/2}} \det(AA^T) + \frac{(k - 1)^{1/(n-d)}}{2(n - d + 1)^{1/2}} \det(AA^T)^{1/2 + 1/(2(n-d))}.$$  

(4)

In addition, the structural Theorem 1 allows us to obtain the lower and upper bounds for $F_k(A)$ in terms of a finite basis of the monomial ideal $I^k(A)$. Let $\| \cdot \|_{\infty}$ denote the maximum norm.

**Theorem 3.** Let $x^{g_1}, \ldots, x^{g_n}$ be a finite basis for the ideal $I^k(A)$ and let $m(A) = \min_{1 \leq i \leq t} \|g_i\|_{\infty}$. The number $F_k(A)$ satisfies the inequalities

$$m(A) - 1 \leq F_k(A) \leq \frac{n - d}{2(n - d + 1)^{1/2}} \det(AA^T) + m(A) \left( \frac{\det(AA^T)}{n - d + 1} \right)^{1/2}.$$  

(5)

3. Third, in Section 6 we propose a way to compute the $k$-holes, i.e., $S_{g<k}(A)$, of the semigroup $S_g(A)$. We give a natural generalization of the proof techniques used by Hemmecke et al. [30] that relies on Hilbert bases to obtain the following theorem:

**Theorem 4.** There exists an algorithm that computes for an integral matrix $A$ a finite explicit representation for the set $S_{g<k}(A)$ of $k$-holes of the semigroup $S_g(A)$. The algorithm computes (finitely many) vectors $h_i \in \mathbb{Z}^d$ and (affine) semigroups $M_i, i \in I$, each given by a finite set of generators in $\mathbb{Z}^d$, such that

$$S_{g<k}(A) = \bigcup_{i \in I} (h_i + M_i).$$
Here $M_i$ could be trivial, that is, $M_i = \{0\}$. In the special case $k = 1$, Theorem 4 was proved in [30].

4. Fourth. For $n$ and $k$ fixed integer numbers, the main result of this paper establishes an efficient way to detect all the $\geq k$-feasible vectors $b$’s, not explicitly one by one, but rather the entire set of $k$-feasible vectors is encoded as a single multivariate generating function, $\sum_{b: \geq k}$-feasible $t^b$.

**Theorem 5.** Let $A \in \mathbb{Z}^{d \times n}$ and let $M$ be a positive integer. Assuming that $n$ and $k$ are fixed, there is a polynomial time algorithm to compute a short sum of rational functions $G(t)$ which efficiently represents a formal sum

$$\sum_{b: \geq k}$-feasible $t^b.$

Moreover, from the algebraic formula, one can perform the following tasks in polynomial time:

(a) Count how many such $b$’s are there (finite because $M$ provides a box).
(b) Extract the lexicographic-smallest such $b$, $\geq k$-feasible vector.
(c) Find the $\geq k$-feasible vector $b$ that maximizes the dot product $c^T b$.
(d) Identical results hold for the problem of the form $Ax \leq b$, $x \in \mathbb{Z}^n$.

Let us explain a bit the philosophy of such theorem using generating functions for those not familiar with this point of view: In 1993 A. Barvinok [12] gave an algorithm for counting the lattice points inside a polyhedron $P$ in polynomial time when the dimension of $P$ is a constant.

The input of the algorithm is the inequality description of $P$, the output is a polynomial-size formula for the multivariate generating function of all lattice points in $P$, namely $f(P) = \sum_{a \in P \cap \mathbb{Z}^n} x_a$, where $x_a$ is an abbreviation of $x_{a_1} x_{a_2} \ldots x_{a_n}$. Hence, a long polynomial with exponentially many monomials is encoded as a much shorter sum of rational functions of the form

$$f(P) = \sum_{i \in I} \pm \frac{x_{u_i}}{(1 - x^{c_1,i})(1 - x^{c_2,i}) \ldots (1 - x^{c_s,i})}. \quad (7)$$

Later on Barvinok and Woods [13] developed a set of powerful manipulation rules for using these short rational functions in Boolean constructions on various sets of lattice points, as well as a way to recover the lattice points inside the image of a linear projection of a convex polytope.

It is very interesting that to prove the last item of the theorem we will use a generalization of a famous results in the theory of integer programming, the theorem of Doignon [26] and Bell and Scarf [14,41]. In this paper we rely on Barvinok’s theory to prove Theorem 5.

It must be remarked that from the results of Barvinok [12] for fixed $n$, but not necessarily fixed $k$, one can decide whether a particular $b$ is $k$-feasible in polynomial time, but more strongly, as a corollary of Theorem 4 one can prove the following theorem for the computation of the $k$-Frobenius number. Recall that given a vector $(a_1, \ldots, a_n)$ and a positive integer $b$ a knapsack problem is a linear Diophantine problem of the form $a_1 x_1 + \ldots + a_n x_n = b$ with $x_i \geq 0$. The question about finding the $k$-Frobenius number is a query over a parametric family of knapsack problems.

**Corollary 2.** Consider the parametric knapsack problem $a^T x = b$, $x \geq 0$ associated with the vector $a = (a_1, \ldots, a_n)^T \in \mathbb{Z}_{\geq 0}^n$ with $\text{gcd}(a_1, \ldots, a_n) = 1$. For fixed positive integers $k$ and $n$, the $k$-Frobenius number can be computed in polynomial time.

This result is a key contribution of this paper. Corollary 2 greatly generalizes a similar celebrated theorem of R. Kannan [32]. Section 7 gives proofs of Theorem 5 and its Corollary 2.
5. The fifth contribution of our article is concerned with \( k \)-feasible knapsack problems. Given \( a = (a_1, \ldots, a_n) \in \mathbb{Z}_{\geq 0}^n \) with gcd\( (a_1, \ldots, a_n) = 1 \), let \( g_k = g_k(a) \) denote the largest positive integer \( b \) such that \( a_1 x_1 + \cdots + a_n x_n = b \) has exactly \( k \) nonnegative integral solutions if such \( b \) exists and zero otherwise. The numbers \( g_k \) were studied by many authors, see e. g. [16], [15], [17] and [42]. In Section 8 we prove the inequality \( g_0 < g_1 \) for \( n = 3 \). This answers in affirmative a question proposed in [17].

6. From Corollary [2] one further can ask: What is the computational complexity of computing the \( k \)-Frobenius number when the dimension \( n \) is fixed but \( k \) is part of the input? On the basis of the results of [27] we suspect that this is an NP-hard problem, but we do not know of the answer. It is then of interest to experiment with the values of \( F_k(a) \) to see the growth for fixed values of \( n \) and possibly predict a formula. The sixth and final contribution of our article is then about practical computation and experimental exploration of the behavior of the \( k \)-Frobenius numbers. In Section 9 we give an algorithm for fast practical computation of the \( k \)-Frobenius numbers using ideas from dynamic programming. Our experiments with knapsacks of three variables \((n = 3)\) provided support for a new conjecture on the asymptotic properties of the average value of the \( k \)-Frobenius numbers.

In what follows we assume that the reader has some familiarity with polyhedral convexity, monomial ideals, toric ideals, semigroup rings, and Gröbner bases as presented in [13] and [21,14].

2 Proof of Theorem [1]

For \( f \in \text{cone}(A) \cap \mathbb{Z}^d \) define

\[
L_{A,f}^k = \{ \lambda \in \mathbb{Z}_{\geq 0}^n : IP_A(f + A\lambda) \text{ is } \geq k \text{ feasible} \},
\]

so that \( S_{g_{\geq k}}(A) = \{ A\lambda : \lambda \in L_{A,0}^k \} \). Define then the monomial ideal \( I^k(A) \) as follows (with its set of exponent vectors denoted by \( E^k(A) \)).

\[
I^k(A) := \langle x^\lambda : \lambda \in L_{A,0}^k \rangle.
\]

To see that the equation \( S_{g_{\geq k}}(A) = \{ A\lambda : \lambda \in E^k(A) \} \) is satisfied it is enough to check that for any \( \lambda_0 \in L_{A,0}^k \) the inclusion \( \lambda_0 + \mathbb{Z}_{\geq 0}^n \subset L_{A,0}^k \) holds. We will prove the following more general statement.

**Lemma 1.** For any \( f \in \text{cone}(A) \cap \mathbb{Z}^d \) and \( \lambda_0 \in L_{A,f}^k \) we have the inclusion

\[
\lambda_0 + \mathbb{Z}_{\geq 0}^n \subset L_{A,f}^k.
\]

**Proof.** Let \( \lambda_0 \in L_{A,f}^k \), so that there exist \( k \) distinct vectors \( \lambda_1, \ldots, \lambda_k \in \mathbb{Z}_{\geq 0}^n \) with

\[
f + A\lambda_0 = A\lambda_1 = \cdots = A\lambda_k.
\]

Take any vector \( \mu \in \mathbb{Z}_{\geq 0}^n \) and set \( \nu = \lambda_0 + \mu \). Then, clearly, we have

\[
f + A\nu = A(\lambda_1 + \mu) = \cdots = A(\lambda_k + \mu),
\]

where all vectors \( \lambda_1 + \mu, \ldots, \lambda_k + \mu \in \mathbb{Z}_{\geq 0}^n \) are distinct. Consequently, \( IP_A(f + A\nu) \) is \( \geq k \) feasible and, thus, \( \nu \in L_{A,f}^k \). Hence (8) holds and the lemma is proved.

Lemma 1 with \( f = 0 \) clearly implies the first claim of Theorem 1. Let us now prove the second claim. Recall that the elements of the set \( S_{g_{\leq k}}(A) \) are also called \( k \)-holes. A \( k \)-hole \( f \) is fundamental if there is no other \( k \)-hole \( h \in S_{g_{\leq k}}(A) \) such that \( f - h \in S_{g_{\geq 1}}(A) \).
Lemma 2. The set of fundamental \( k \)-holes is a subset of the zonotope

\[
P = \{ A \lambda : \lambda \in [0,1]^n \} .
\]

Proof. Let \( f \in \text{Sg}_{<k}(A) \) be a fundamental \( k \)-hole. We can write

\[
f = A \lambda, \; \lambda \in \mathbb{Q}^n_{\geq 0}.
\]

Suppose \( f \notin P \). Then for some \( j \) we must have \( \lambda_j \geq 1 \). Thus, denoting by \( A_j \) the \( j \)th column vector of \( A \), the element \( f' = f - A_j \) is a \( k \)-hole as any \( k \) distinct solutions for \( IP_A(f') \) would correspond to \( k \) distinct solutions for \( IP_A(f) \). Thus we get a contradiction with our choice of \( f \) as a fundamental \( k \)-hole. This implies \( \lambda_j < 1 \) for all \( j \) and, consequently, \( f \in P \). The lemma is proved.

Lemma 2 shows, in particular, that the number of fundamental \( k \)-holes is finite. Let us fix a fundamental \( k \)-hole \( f \). If the set \( L^k_{A,f} \) is empty then \( f + A \lambda \) is a \( k \)-hole for all \( \lambda \in \mathbb{Z}^n_{\geq 0} \). Assume now that \( L^k_{A,f} \) is not empty and consider the monomial ideal \( I^k_{A,f} \subset \mathbb{Q}[x_1,\ldots,x_n] \) defined as

\[
I^k_{A,f} = \langle x^\lambda : \lambda \in L^k_{A,f} \rangle .
\]

Then, in view of \( \text{[6]} \), \( f + A \lambda \) is not a \( k \)-hole if and only if \( x^\lambda \in I^k_{A,f} \).

Thus we need to write down the set \( C(I^k_{A,f}) \) of exponents of standard monomials for the ideal \( I^k_{A,f} \). Any such exponent \( \lambda \in C(I^k_{A,f}) \) corresponds to the \( k \)-hole \( f + A \lambda \).

By Theorem 3 in Chapter 9 of \([21]\), the set \( C(I^k_{A,f}) \) can be written as a finite union of translates of coordinate subspaces of \( \mathbb{Z}^n_{\geq 0} \). Since the number of fundamental \( k \)-holes is finite, the second claim of Theorem \([4]\) is proved.

3 Asymptotic structure of \( \text{Sg}_{\geq k}(A) \)

In this section we assume that \( A \in \mathbb{Z}^{d \times n}, 1 \leq d < n \), is an integral \( d \times n \) matrix satisfying

\[
i) \; \gcd( \det(A_{I_d}) : A_{I_d} \text{ is an } d \times d \text{ minor of } A) = 1,
\]

\[ii) \; \left\{ x \in \mathbb{R}_{\geq 0}^n : Ax = 0 \right\} = \{0\} . \tag{9}
\]

In the important special case \( d = 1 \) the matrix \( A = a^T \) is just a row vector with \( a = (a_1,\ldots,a_n)^T \in \mathbb{Z}^n \) and \( \text{[10]} \) \( i) \) says that \( \gcd(a_1,\ldots,a_n) = 1 \). Due to the second assumption \( \text{[10]} \) \( ii) \) we may assume that all entries of the vector \( a \) are positive. It follows that the largest integral value \( b \) such that the problem \( IP_A(b) \) is \( < k \)-feasible, the \( k \)-Frobenius number \( F_k(a) \), is well-defined. Clearly, for \( d = 1 \) we have the inclusion

\[
\text{int}(F_k(a) + \mathbb{R}_{\geq 0}) \cap \mathbb{Z} \subset \text{Sg}_{\geq k}(a^T) , \tag{10}
\]

where \( \text{int}(\cdot) \) denotes the interior of the set.

In general, the structure of the set \( \text{Sg}_{\geq k}(A) \), apart from a few special cases, is not well understood. It is known that, in analogy with \( \text{[10]} \), \( \text{Sg}_{\geq k}(A) \) can be decomposed into the set of all integer points in the interior of a certain translated cone and a complex complementary set. More recent results (see \( \text{[19]} \)) attempt to estimate the location of such a cone along the fixed direction \( v = A \mathbf{1} \), where \( \mathbf{1} \) is the all-1-vector, in the interior of \( \text{cone}(A) \). The choice of \( v \) as the direction vector is dated back to the paper of Khovanskii \([20]\) for \( k = 1 \). In general, given any rational vector \( u \) in the interior of \( \text{cone}(A) \), the multiple \( tu \) will, for large enough \( t \in \mathbb{Z} \), lie in \( \text{Sg}_{\geq k}(A) \). Hence the name asymptotic structure.
In this paper we consider a generalization of the Frobenius number that reflects \( \geq k \)-feasibility properties of the whole family of the problems \( IP_A(b) \), when \( b \) runs over all integer vectors in the interior of the cone \( \text{cone}(A) \). Given a direction vector \( b \in \text{int}(\text{cone}(A)) \cap \mathbb{Z}^d \) put 
\[
g_k(A,b) = \min\{t \geq 0 : \text{int}(tb + \text{cone}(A)) \cap \mathbb{Z}^d \subset S_{g \geq k}(A)\}.
\]
We define the \( k \)-Frobenius number associated with \( A \) as 
\[
F_k(A) = \max\{g_k(A,b) : b \in \text{int}(\text{cone}(A)) \cap \mathbb{Z}^d\}.
\]
The number \( g_k(A) = g_k(A,v) \) was called in [6] the diagonal \( k \)-Frobenius number of \( A \). A lower bound for \( g_k(A) \) (and thus, by definition of \( g_k(A) \), for \( F_k(A) \)) was given in [6, Theorem 1.3]. Next we derive the lower and upper bounds for \( F_k(A) \) presented in Theorem 2 and Theorem 3.

Before we start the proofs it is worth remarking they will be based on the results obtained in [4], [6] and the structural Theorem 1.

### 4 Proof of Theorem 2

First we show that the \( k \)-Frobenius number \( F_k(A) \) is bounded from above by the (suitably normalized) number \( g_k(A) \).

**Lemma 3.**
\[
F_k(A) \leq \left( \frac{\det(AAT)}{n-d+1} \right)^{1/2} g_k(A) .
\]

**Proof.** Put for convenience \( \gamma = \left( \frac{\det(AAT)}{n-d+1} \right)^{1/2} \). As it was shown in the proof of Lemma 1.1 in [4], for any \( b \in \text{int}(\text{cone}(A)) \cap \mathbb{Z}^d \) the vector \( \gamma b \) is contained in \( v + \text{cone}(A) \). Therefore \( \gamma b + \text{cone}(A) \subset v + \text{cone}(A) \) and, consequently,
\[
\text{int}(g_k(A)\gamma b + \text{cone}(A)) \cap \mathbb{Z}^n \subset \text{int}(g_k(A)v + \text{cone}(A)) \cap \mathbb{Z}^n \subset S_{g \geq k}(A) .
\]
Hence for any \( b \in \text{int}(\text{cone}(A)) \cap \mathbb{Z}^d \) we have \( g_k(A,b) \leq g_k(A)\gamma \). Therefore \( F_k(A) \leq g_k(A)\gamma \) and the lemma is proved.

The diagonal \( k \)-Frobenius number \( g_k(A) \) in its turn is bounded from above in terms of \( A \) and \( k \) due to the following result.

**Theorem 6 (Theorem 1.2 in [6]).** The diagonal \( k \)-Frobenius number associated with \( A \) satisfies the inequality
\[
g_k(A) \leq \frac{n-d}{2} \left( \det(AAT) \right)^{1/2} + \frac{(k-1)^{1/(n-d)}}{2} \left( \det(AAT) \right)^{1/2(n-d)} .
\]

Combining (11) and (12) we obtain the inequality (5).
5 Proof of Theorem 3

The set of exponents $E^k(A)$ of the monomial ideal $I^k(A) = \langle x^{g_1}, \ldots, x^{g_t} \rangle$ has the form

$$E^k(A) = \bigcup_{i=1}^{t} (g_i + \mathbb{Z}_{\geq 0}^n).$$

(13)

By (13), any $g \in E^k(A)$ has $||g||_\infty \geq m(A)$. Therefore the point $(m(A) - 1) \mathbf{1} \notin E^k(A)$ and, by Theorem 1 (i), we obtain $A((m(A) - 1) \mathbf{1}) = (m(A) - 1) v \notin S_{g,k}(A)$. Therefore, by the definition of $g_k(A)$,

$$m(A) - 1 \leq g_k(A) \leq F_k(A).$$

This proves the lower bound in (6).

To derive the upper bound, we will show first that $g_k(A)$ satisfies the inequality

$$g_k(A) \leq g_1(A) + m(A).$$

(14)

Let us choose any $y \in \text{int}((g_1(A) + m(A))v + \text{cone}(A)) \cap \mathbb{Z}^d$. To prove (14), it is enough to show that $y \in S_{g,k}(A)$. Consider the point $y' = y - m(A)v$. Since $y' \in \text{int}(g_1(A)v + \text{cone}(A)) \cap \mathbb{Z}^d$, we have $y' \in S_{g,k}(A)$. Therefore, there exists $z \in \mathbb{Z}_{\geq 0}^n$ such that $Az = y'$. Hence $A(m(A) \mathbf{1} + z) = m(A)v + Az = y$. Finally, observe that $m(A) \mathbf{1} \in E^k(A)$ by (13), and hence $m(A) \mathbf{1} + z \in (m(A) \mathbf{1} + \mathbb{Z}_{\geq 0}^n) \subset E^k(A)$. Consequently, $y = A(z + m(A) \mathbf{1}) \in S_{g,k}(A)$ and the inequality (14) is proved. The upper bound in (6) now follows from (11), (14) and (12) with $k = 1$.

6 Computing $k$-holes via Hilbert bases

In this section we combine the results of Hemmecke et al. [30] with our techniques to compute the elements of $S_{g,k}(A)$ proving Theorem 4. We present an algorithm to compute an explicit representation of $S_{g,k}(A)$, even for an infinite case, using semigroups. We remark that this explicit representation need not be of polynomial size in the input size of $A$.

In view of the proof of Theorem 1 (ii), it is enough to compute all fundamental $k$-holes and then for each fundamental $k$-hole $f$ with nonempty set $L^k_{A,f}$ compute the standard monomials of the ideal $I^k_{A,f}$. If the set $L^k_{A,f}$ is empty, the set of all $k$-holes $H_k$ contains the translated semigroup $f + S_g(A)$. By Lemma 2 all fundamental $k$-holes are located in a zonotope $P = \{ A \lambda : \lambda \in [0,1]^n \}$. Thus, with a straightforward generalization of the approach proposed in Hemmecke et al. [30], the fundamental $k$-holes the can be computed by using a Hilbert basis of the cone $cone(A)$.

Let $f$ be a fundamental $k$-hole. Recall that for a nonempty set $L^k_{A,f}$ the monomial ideal $I^k_{A,f} \subset \mathbb{Q}[x_1, \ldots, x_n]$ is defined as

$$I^k_{A,f} = \langle x^\lambda : \lambda \in L^k_{A,f} \rangle$$

and $f + A \lambda$ is not a $k$-hole if and only if $x^\lambda \in I^k_{A,f}$.

Thus we need to compute the exponents of standard monomials for the ideal $I^k_{A,f}$. Any such exponent $\lambda \in \mathbb{Z}_{\geq 0}^n$ corresponds to the $k$-hole $f + A \lambda$. The exponents of standard monomials can be computed explicitly from a set of generators of the ideal. Hence, it is enough to find the generators of $I^k_{A,f}$. Let us fix an ordering $\prec$ in $\mathbb{Z}_{\geq 0}^n$. The minimal generators for the ideal $I^k_{A,f}$ correspond to the $\prec$-minimal elements of the set

$$L^k_{A,f} = \{ \lambda \in \mathbb{Z}_{\geq 0}^n : \exists \text{ distinct } \mu_1, \ldots, \mu_k \in \mathbb{Z}_{\geq 0}^n \text{ such that } f + A \lambda = A \mu_1 = \cdots = A \mu_k \}.$$
For computational purposes it is enough to compute a set of vectors of $L^k_{A,f}$ that contains all the $\prec$-minimal elements. We will proceed as follows. Let $K$ be a complete graph with the vertex set $V = \{1, 2, \ldots, k\}$. By a weighted orientation $H$ of $K$ we will understand a weighted directed graph $H = (V, E)$ such that any two vertices of $H$ are connected by a directed edge $e \in E$ with a weight $w(e) \in \{1, \ldots, n\}$.

Let $\mathcal{S}$ be set of all weighted orientations of $K$. For each $H \in \mathcal{S}$ we construct the following two auxiliary sets: the set
\[
L_H = \{ \lambda \in \mathbb{Z}_{\geq 0}^n : \exists \mu_1, \ldots, \mu_k \in \mathbb{Z}_{\geq 0}^n \text{ such that } f + A\lambda = A\mu_1 = \cdots = A\mu_k \\
\text{and } (\mu_i)_{w(e)} \leq (\mu_j)_{w(e)} - 1 \text{ for each } e = (i, j) \in E \}
\]
and the set
\[
M_H = \{ (\lambda, \mu_1, \ldots, \mu_k) \in \mathbb{Z}_{\geq 0}^{(k+1)n} : f + A\lambda = A\mu_1 = \cdots = A\mu_k \\
\text{and } (\mu_i)_{w(e)} \leq (\mu_j)_{w(e)} - 1 \text{ for each } e = (i, j) \in E \}.
\]

Then, in particular, $L^k_{A,f} = \bigcup_{H \in \mathcal{S}} L_H$, where the union is taken over all orientations in $H \in \mathcal{S}$.

We will need the following result.

**Lemma 4.** Let $\lambda_0$ be a $\prec$-minimal element of $L_H$. Then there exists a $\prec$-minimal element of $M_H$ of the form $(\lambda_0, \mu_1, \ldots, \mu_k)$.

**Proof.** Let $\lambda_0$ be a $\prec$-minimal element of $L_H$. Suppose on contrary, for every $(\mu_1, \ldots, \mu_k) \in \mathbb{Z}_{\geq 0}^n$ the vector $(\lambda_0, \mu_1, \ldots, \mu_k)$ is not a $\prec$-minimal element of $M_H$. Let $(\hat{\mu}_1, \ldots, \hat{\mu}_k)$ be a $\prec$-minimal element of the set
\[
M_H|_{\lambda=\lambda_0} = \{ (\mu_1, \ldots, \mu_k) \in \mathbb{Z}_{\geq 0}^n : f + A\lambda_0 = A\mu_1 = \cdots = A\mu_k \\
\text{and } (\mu_i)_{w(e)} \leq (\mu_j)_{w(e)} - 1 \text{ for each } e = (i, j) \in E \}.
\]

By the assumption, there exists a vector $(\lambda', \mu'_1, \ldots, \mu'_k) \in M_H$ such that $(\lambda', \mu'_1, \ldots, \mu'_k) \prec (\lambda_0, \hat{\mu}_1, \ldots, \hat{\mu}_k)$ and $(\lambda', \mu'_1, \ldots, \mu'_k) \neq (\lambda_0, \hat{\mu}_1, \ldots, \hat{\mu}_k)$. If $\lambda' \neq \lambda_0$ we get a contradiction to the $\prec$-minimality of $\lambda_0$ in $L_H$. On the other hand, if $\lambda' = \lambda_0$ we get a contradiction to the $\prec$-minimality of $(\hat{\mu}_1, \ldots, \hat{\mu}_k)$ in $M_H|_{\lambda=\lambda_0}$.

In view of Lemma 4, to compute a generating set for $L^k_{A,f}$ (or to determine that $L^k_{A,f}$ is empty) it is now enough to compute the set of all minimal elements for $M_H$, $H \in \mathcal{S}$ and remove the last $kn$ components from each of them.

### 7 Proof of Theorem 5

We use the technic of rational generating functions developed by Barvinok and Woods in [12,13] (see also the book [11]). We wish to prove a representation theorem of a set of lattice points as a sum $\sum_{k \geq k - \text{feasible}} \hat{\psi}$. First we need a lemma

**Lemma 5.** Let $n$ be a constant. Given a positive integer $M$ and the associated $n$-dimensional box $B_M = [0, M]^n$, there exists an integer linear objective function $\hat{c}_M^T x$ such that $\hat{c}_M^T (y_i - y_j) \neq 0$ for all pairs of non-zero lattice points $y_i, y_j$ inside the box $B_M$. One can find such vector in polynomial time.
Proof: Let $s$ be a single auxiliary (real) variable and the associated $n$-dimensional vector $c(s) = (1, s, s^2, s^3, \ldots, s^{n-1})^T$. Now for each of the $L = M^n(M^n - 1)/2$ pairs of non-zero lattice vectors $y_i - y_j$ we construct one univariate polynomial $f_{i,j}(s) = c(s)^T(y_i - y_j)$ (since $y_i, y_j$ are distinct the polynomial $f_{i,j}$ is not identically zero). These are polynomials of degree $n - 1$ so they can only have at most $n - 1$ real roots each. Note also that these are polynomials all of whose coefficients are integer numbers between $-M$ and $M$, that means, by the famous Cauchy bound on the absolute values of roots of univariate polynomials that any of the real roots of any $f_{i,j}(s)$ must be bounded in above by $1 + M$. Thus taking, for example, the value $s_0 = M + 2$ gives $c_M = c(s_0)$ as an integer vector that totally orders all lattice points in the box $B_M$. Note that the bit-size description of $c_M$ is polynomial in the input namely $n$, and $\log(M)$ because the entries are the first $n - 1$ powers of $M$. The lemma is proved.

Now, recall that $A$ is an integral $d \times n$ matrix and $n,k$ are constants. Let $M$ be a positive integer. We can define the polyhedron (note $X_i$ denotes an $n$-dimensional vector so this polytope lives in $nk$-dimensional space):

$$Q(A,k,M) = \{(X_1, X_2, \ldots, X_k) : AX_1 = \cdots = AX_k, e^T_M X_i \geq e^T_M X_{i+1} + 1, \quad \text{for } i = 1, \ldots, k-1 \text{ and } X_i \geq 0, M \geq AX_1 \geq 0 \}.$$ 

One can use Barvinok’s algorithm to compute the generating function of the lattice points of $Q(A,k,M)$. This is a polytope that has the key property that all its integer points represent distinct $k$-tuples of integer points that are in some parametric polyhedron $P_A(b) = \{x : Ax = b, x \geq 0 \}$. When we turn to monomials, $z_1^{X_1}z_2^{X_2} \cdots z_k^{X_k}$ has only those exponents where $X_i \neq X_j$. Namely, this is precisely the set of all monomials coming from $k$-tuples of distinct vectors in $\mathbb{Z}_{\geq 0}^n$ that give the same value $AX_1 = AX_2 = \cdots = AX_k$.

We can do Boolean operations on the generating functions representing sets of lattice points by the following result:

Lemma 6 (Corollary 3.7 in [13]). Assume the dimension $d$ is a fixed constant. Let us fix $l$ (the number of sets $S_i \subset \mathbb{Z}^d$) and $r$ (the number of binomials in each fraction of the generating function $f(S_i)$). Then there exists an $s = s(l,r)$ and a polynomial time algorithm, which, for any $l$ (finite) sets of lattice points $S_1, \ldots, S_l \subset \mathbb{Z}^d$ given by their generating functions $f(S_i)$ and a set $S \subset \mathbb{Z}^d$ defined as a Boolean combination of $S_1, \ldots, S_m$, computes $f(S)$ in the form

$$f(S) = \sum_{i \in I} \gamma_i \frac{x^{u_i}}{(1 - x^{v_{ij}}) \cdots (1 - x^{v_{ij}})},$$

where $\gamma_i \in \mathbb{Q}$, $u_i, v_{ij} \in \mathbb{Z}^d$ and $v_{ij} \neq 0$ for all $i,j$.

Finally another key subroutine introduced by Barvinok and Woods is the following Projection Theorem.

Lemma 7 (Theorem 1.7 in [13]). Assume the dimension $n$ is a fixed constant. Consider a rational polytope $P \subset \mathbb{R}^n$ and a linear map $T : \mathbb{Z}^n \rightarrow \mathbb{Z}^d$ such that $T(\mathbb{Z}^n) \subset \mathbb{Z}^d$. There is a polynomial time algorithm which computes a short representation of the generating function $f(T(P \cap \mathbb{Z}^n), x)$.

In this case we apply a very simple linear map $T(X_1, X_2, \ldots, X_k) = AX_1$, by multiplication with $A$. This yields of course for each $k$-tuple (which has $X_i \neq X_j$) the corresponding right-hand side vector $b = AX_1$ that has at least $k$-distinct solutions. The final generating expression will be

$$f = \sum_{b \in \text{projection of } Q(A,k,M)} t^b.$$
Which is the desired short rational function which efficiently represents the sum $\sum_{\geq k-\text{feasible}} t^b$. This proves the main result in the body of the paper for $\geq k$-feasibility. Because if one knows a description for $S_{g \geq k}(A)$ and $S_{g \geq k+1}(A)$ one knows $S_{g=k}(A) = S_{g \geq k}(A) \cap S_{g \geq k+1}(A)$ and $S_{g<k}(A) = S_g(A) \setminus S_{g \geq k}(A)$, the Boolean properties of generating functions in Lemma 6 give the theorem in all three cases.

Now we move to prove Parts (a) to (d) of the theorem.

**Part (a)** If we have a generating function representation of

$$\sum_{\geq k-\text{feasible}} t^b,$$

it has the form

$$f(t) = \sum_{i \in I} \alpha_i \frac{t^{p_i}}{(1 - t^{a_{i1}}) \cdots (1 - t^{a_{ik}})}.$$

Note that by specializing at $t = (1, \ldots, 1)$, we can count how many $b$’s are $\geq k$-feasible (again the set is finite because it fits inside a box). Remark the substitution is not immediate since $t = (1, \ldots, 1)$ is a pole of each fraction in the representation of $f$. This problem is solvable because it has been shown by Barvinok and Woods that this computation can be handled efficiently (see Theorem 2.6 in [13] for details) and this proves Part (a).

**Part (b)** This item is a direct corollary of the following extraction lemma.

**Lemma 8** (Lemma 8 in [23] or Theorem 7.5.2 in [24]). Assume the dimension $n$ is fixed. Let $S \subseteq \mathbb{Z}_+^n$ be nonempty and finite set of lattice points. Suppose the polynomial $f(S; z) = \sum_{\beta \in S} z^\beta$ is represented as a short rational function and let $c$ be a cost vector. We can extract the (unique) lexicographic largest leading monomial from the set $\{ x^\alpha : \alpha \cdot c = L, \alpha \in S \}$, where $L := \max\{ \alpha \cdot c : \alpha \in S \}$, in polynomial time.

**Part (c)** Barvinok and Woods developed a way to do monomial substitutions (not just $t_i = 1$ as we used in Part (a)), where the variable $t_i$ in the current series, is replaced by a new monomial $z_1^{t_1} z_2^{t_2} \cdots z_r^{t_r}$. Note that the rational generating function $f = \sum_{b \in Q^d} b^b$ can give the evaluations of the $b$’s for a given objective function $c \in \mathbb{Z}^d$. If we make the substitution $t_i = z^{c_i}$, the above equation yields a univariate rational function in $z$:

$$f(z) = \sum_{i \in I} E_i \prod_{j=1}^d (1 - z^{c_{ij}}).$$

Moreover $f(z) = \sum_{k \in Q^d} z^c b$. Thus we just need to find the (lexicographically) largest monomial in the sum in polynomial time. But this follows from Part (b).

**Part (d)** To prove this result we will use a recent generalization of Doignon-Bell-Scarf’s theorem [7]. Any problem of the form $Ax \leq b$ can be transferred to a problem of the form $Ax + Is = b$ by adding slack variables $s$. Then such a system is in the shape of the main part of Theorem 5 except we need a fixed number of columns. To see this is possible, by Theorem 1 in [7], if $Ax \leq b$ has $k$-solutions then, exactly the same integer solutions appear in a subsystem $A_{Sx} \leq b$ with no more than a constant $c(n, k)$ rows. Thus we need to add at most $n + c(k, n)$ slack variables. Of course we do not know which rows form the system but there are only $\binom{d}{k}$ possibilities for subsystems $A_{Sx} + Is = b$ (each subsystem has a fixed number of columns now, thus it can be solved in polynomial time). Therefore, we can also decide for which $b$’s the polyhedron has $k$ points $Ax \leq b$ in polynomial time (again when encoded in a rational function format).
To conclude we see how to compute the $k$-Frobenius number efficiently.

**Proof of Corollary 2**

We start by observing that there is an upper bound for the $k$-Frobenius number. Indeed Theorem 1.1 in [3] gives already an upper bound that is certainly smaller than $M = k(n-1)\alpha_{1} 2 \cdots a_{n}$. The $k$-Frobenius number must be smaller and thus we will use in the bounding box created in our Theorem 5.

Next we claim the same generating function descriptions obtained in Theorem 5 can be also obtained for the sets of those $b$ which are $k$-feasible, $\geq k$-feasible, or $< k$-feasible with the added condition that $b_{i} \leq M$. This is because the generating functions of those sets of $b$'s can be obtained from the set of $b$'s encoded by Theorem 5 through Boolean operations (intersection, unions, complements). Indeed we clearly have $S_{ \geq k+1}(A) \setminus S_{ \geq k}(A) = S_{ \geq k}(A) \setminus S_{ \geq k}(A)$ and $S_{ \leq k}(A) = S_{ \geq k}(A) \setminus S_{ \leq k}(A)$. The same identities hold under the intersection with the box $B_{M} = [0, M]^{d}$, thus the claim follows.

We may see now that Corollary 2 follows directly from what we achieved in Theorem 5 and the Boolean operation Lemma of Barvinok and Woods. Indeed, from Theorem 5 we have a rational function representation of the $k$-feasible $b$ for the knapsack problem $f(t) = \sum_{t \in T} E_{t} \prod_{j=1}^{n} (1 - t^{-1} a_{j})$ = $\sum_{b \in \text{projection } \text{of} Q(A, k, M) \cap \mathbb{Z}^{d}, \geq k}$-feasible $t^{c-b}$. Clearly the $k$-Frobenius number is simply the largest (lexicographic) $b$, such that $t^{b}$ is not in $f(t)$, it is in its complement. Note the choice of bound $M$ is such that we indeed have the $k$-Frobenius number inside. Then, for the complement $S = \mathbb{Z}_{+} \setminus S$, we compute the generating function $f(S; x) = (1 - t)^{-1} - f(t)$ and then we compute the largest such $t^{b}$ in the complement using Lemma 8.

8 Integers with exactly $k$ representations

Let $a = (a_{1}, \ldots, a_{n}) \in \mathbb{Z}_{\geq 0}^{n}$ with $\gcd(a_{1}, \ldots, a_{n}) = 1$. Recall that $g_{k}(a)$ denotes the largest positive integer $b$ such that $a_{1}x_{1} + \cdots + a_{n}x_{n} = b$ has exactly $k$ integral nonnegative solutions if such $b$ exists and zero otherwise. In other words, a positive $g_{k}$ is the largest integer that has exactly $k$ representations by $a_{1}, \ldots, a_{n}$. In the case $n = 2$ Beck and Robins [16] obtained the formula

$$g_{k-1}(a_{1}, a_{2}) = k a_{1} a_{2} - a_{1} - a_{2}.$$  \hspace{1cm} (16)

Note that $F_{k}(a_{1}, a_{2}) = g_{k-1}(a_{1}, a_{2})$ and, in general, $F_{k}(a)$ = $\max\{g_{i}(a) : i \leq k - 1\}$.

Given a fixed vector $a$, the behavior of the sequence $\{g_{i}(a)\}_{i=0}^{\infty}$ is far from being simple for $n \geq 3$. For instance, it has been observed in Brown et al. [17] that $g_{i}(a_{1}, a_{2}, a_{3})$ is not necessarily increasing with $i$. For example, $g_{14}(3, 5, 8) = 52$ whereas $g_{15}(3, 5, 8) = 51$ and therefore in that particular case $g_{14} > g_{15}$. Furthermore, Shallit and Stankevicz [12] proved that for $i > 0$ and $n = 5$, the quantity $g_{0} - g_{i}$ is arbitrarily large and positive. They also give an example of $g_{0} > g_{1}$ for $n = 4$.

For $n = 3$ Brown et al. [17] posed the question whether or not the inequality $g_{0} < g_{1}$ always holds. In what follows we answer this question in affirmative.

**Theorem 7.** Given $a_{1} < a_{2} < a_{3} \in \mathbb{Z}_{\geq 0}$, we have

$$g_{0}(a_{1}, a_{2}, a_{3}) < g_{1}(a_{1}, a_{2}, a_{3}).$$

To prove this theorem, we first consider the case in which all coefficients are pairwise relatively prime.

**Lemma 9.** Let $a_{1} < a_{2} < a_{3}$ be the pairwise relatively prime positive integers. Then

$$g_{0}(a_{1}, a_{2}, a_{3}) < g_{1}(a_{1}, a_{2}, a_{3}).$$
Proof. Let $f = g_0(a_1, a_2, a_3)$ denote the Frobenius number of the vector $(a_1, a_2, a_3)$. Then

$$a_1x_1 + a_2x_2 + a_3x_3 = f$$

(17)

has no nonnegative integral solution. On the other hand

$$a_1x_1 + a_2x_2 + a_3x_3 = f + a_1$$

(18)

has at least one nonnegative integral solution. We will prove that this solution is unique. Let $\tilde{x}$ be any nonnegative integral solution to (18). Observe that $\tilde{x}$ has at least one nonnegative integral solution. We will prove that this solution is unique. Let $\tilde{x}$ be any nonnegative integral solution for (17). Therefore $\tilde{x} = (0, \tilde{x}_2, \tilde{x}_3)$. Consider by contradiction that $\tilde{x} = (0, \tilde{x}_2, \tilde{x}_3)$ is another nonnegative integral solution to (17). Therefore $\tilde{x} = (0, \tilde{x}_2, \tilde{x}_3)$. Consider by contradiction that $\tilde{x} = (0, \tilde{x}_2, \tilde{x}_3)$ is another nonnegative integral solution to (18). Then $a_2(\tilde{x}_2 - \tilde{x}_2) + a_3(\tilde{x}_3 - \tilde{x}_3) = 0$. In particular, since $\gcd(a_2, a_3) = 1$, this implies $|\tilde{x}_2 - \tilde{x}_2| = la_3$ with $l$ a natural number, which in turn implies that either $\tilde{x}_2 \geq a_3$ or $\tilde{x}_2 \geq a_3$. Assume w.l.o.g. that $\tilde{x}_2 \geq a_3$, and since $(0, \tilde{x}_2, \tilde{x}_3)$ is a nonnegative integral solution to (18), this implies that $f + a_1 \geq a_2a_3$ and hence $f \geq a_2a_3 - a_1$ which is in contradiction with the fact that $f = g_0(a_1, a_2, a_3) \leq g_0(a_2, a_3) \leq g_0(a_2, a_3) = a_2a_3 - a_2 - a_3$.

The following result was proved in [17].

Lemma 10 (Theorem 1 in Brown et al. [17] with $k = 3$). Let $d = \gcd(a_2, a_3)$ and $j \in \mathbb{Z}_{\geq 0}$ then either $g_j(a_1, a_2, a_3) = dg_j(a_1, a_2/d, a_3/d) + (d-1)a_1$ or $g_j(a_1, a_2, a_3) = g_j(a_1, a_2/d, a_3/d) = 0$, i.e., no right-hand-side achieves exactly $j$ integral solutions.

To prove Theorem 1 we will reduce the general case to the case of pairwise relatively prime coefficients. Consider a triple $(a_1, a_2, a_3)$. If the coefficients are pairwise relatively prime, the result follows from Lemma 9. Assume that there is some g.c.d. different from 1 for a pair of coefficients. From Lemma 10 we can get rid of the g.c.d. and that does not change the relative order between $g_0$ and $g_1$. By applying at most three times Lemma 10 we come back to the case where all coefficients are pairwise relatively prime and the result follows. The theorem is proved.

9 Computing $F_k(a)$ by dynamic programming and the behavior of $F_k(a_1, a_2, a_3)$

The computational aspects of the classical Frobenius problem were studied by many authors (see [10] and references therein). In this section, we propose a practical dynamic programming approach that allows us to compute the number of integral solutions to the knapsack problems and the k-Frobenius numbers.

9.1 A simple dynamic programming algorithm for $F_k(a)$

Given $a_1, \ldots, a_n \in \mathbb{Z}_{>0}$, we denote by $T_i(b)$ the number of integral solutions of the knapsack problem $\sum_{i=1}^n a_ix_i = b$, $x \in \mathbb{Z}_{\geq 0}^n$, satisfying $x_j = 0$ for $j < i$ and $x_i \geq 1$, i.e., $T_i(b)$ counts the number of integral solutions of the knapsack problem where the smallest nonzero index is $i$. The idea of the algorithm is to update an array $T_i(b)$ for increasing $b$ and for all $i$. The following observation allows us to initialize the dynamic programming approach.

Lemma 11. $T_i(a_i) = 1$ and $T_i(b) = 0$ for all $0 \leq b \leq a_i - 1$.

The following lemma explains how to update the function $T$. 
Lemma 12. Given $b \neq a_i$,

$$T_i(b) = \sum_{j=1}^{n} T_j(b - a_i). \quad (19)$$

Proof. We first prove that (19) holds with $\geq$ instead of $=$. Indeed consider any nonnegative integral solution $\tilde{x}$ to $\sum_{i=1}^{n} a_i x_i = b - a_i$ with $\tilde{x}_j = 0$ for all $1 \leq j \leq i - 1$, it can be transformed into a nonnegative integral solution for $\sum_{i=1}^{n} a_i x_i = b$ by considering $\tilde{x} + e_i$. Obviously the first $(i - 1)$ components are still zero and the $i^{th}$ component is positive.

We now prove that (19) holds with $\leq$. Consider a solution $\hat{x} \in \mathbb{Z}_{\geq 0}^n$ with $\hat{x}_j = 0$ for all $1 \leq j \leq i - 1$ and $\hat{x}_i \geq 1$ to $\sum_{i=1}^{n} a_i x_i = b$. By subtracting 1 from the $i^{th}$ component, we obtain a nonnegative integer solution to $\sum_{i=1}^{n} a_i x_i = b - a_i$ where the first $i - 1$ components are zero.

Using Lemma 11 and Lemma 12 we can fill in an array $T_i(b)$ starting from $b = 0$ for increasing values of $b$. Obtaining the array $T$ allows us to count the number of different solutions.

Lemma 13. The number of nonnegative integral solutions to $\sum_{i=1}^{n} a_i x_i = b$ is equal to $\sum_{i=1}^{n} T_i(b)$.

Proof. This follows from the fact that any integral solution to $\sum_{i=1}^{n} a_i x_i = b$ is counted exactly in one set corresponding to the smallest index for which $x_i$ is nonzero.

To determine the $k$-Frobenius number, we need to know the largest $b$ that is $< k$-feasible. It is therefore important to determine a stopping criterion for the dynamic programming algorithm. A first obvious criterion is to use the upper bound for $b$ given in [3]. It turns out that this upper bound is very often too large compared to the actual $k$-Frobenius number and leads to longer computation times. The following lemma allows us to interrupt the computation with the guarantee for a $k$-Frobenius number earlier.

Lemma 14. Assume that $a_1 < a_2 < \cdots < a_n$ and that $\sum_{i=1}^{n} a_i x_i = b$ has at least $k$ integral solutions for all $\hat{b} \leq b \leq \hat{b} + a_1$. Then $\sum_{i=1}^{n} a_i x_i = b$ has at least $k$ integral solutions for all $b \geq \hat{b}$.

Proof. This follows from the fact that $T_1(b) = \sum_{i=1}^{n} T_i(b - a_1)$ and that the number of integral solutions of $\sum_{i=1}^{n} a_i x_i = b$ is at least $T_1(b)$.

We now have all the necessary ingredients to describe a dynamic programming-based algorithm.

**Algorithm 1** DP algorithm for the $k$-Frobenius number

Require: $a_1 < a_2 \cdots < a_n$, $k \geq 1$

$T_i(a_i) = 1$ for all $i = 1, \ldots, n$

$T_i(b) = 0$ for $i = 1, \ldots, n$ and $b < a_i$

$b := a_1 + 1$

while $\exists \hat{b} \in [b - a_1, b - 1]$ with $\sum_{i=1}^{n} T_i(\hat{b}) < k$ do

for $i := 1$ to $n$ do

$T_i(b) := \sum_{j=1}^{n} T_j(b - a_i)$

end for

$b := b + 1$

end while

Return the largest $b$ that has less than $k$ solutions

We have done a number of computational experiments in order to evaluate the empirical complexity of Algorithm 1. Our implementation of the algorithm was in standard C code with CPU
Intel Core i7-975, 4 cores, 8 threads, CPU clock 3.33 GHz. In the experiments we checked the average time needed to compute the $k$-Frobenius number for some common values of $n$ and $a_1$, as well as the dependency on $k$. The algorithm demonstrated surprisingly good performance. For instance, to check the dependency on $k$, we fixed the dimension to $n = 10$ and the range of values for $a_i$ to $[2^{14}, 2^{16}]$. For each value of $k$, we run 20 experiments. The summary of the results is reported in Table 1. We observe that the average time grows very slowly with $k$. We utilize this property of Algorithm 1 in the next section.

9.2 Experiments on the $k$-Frobenius number $F_k(a_1, a_2, a_3)$

In this section we report the results of several experiments concerning the average behavior of the $k$-Frobenius number $F_k(a)$ and make a conjecture on the basis of these results. The experiments were performed using the dynamic programming algorithm introduced in Section 9.1.

Let $G_T = \{ a = (a_1, a_2, a_3) \in \mathbb{Z}_0^3 : \gcd(a_1, a_2, a_3) = 1, ||a||_\infty \leq T \}$ and let $A_k(T)$ denote the average value of the (normalized) $k$-Frobenius number over $G_T$, that is

$$A_k(T) = \frac{1}{|G_T|} \sum_{(a_1, a_2, a_3) \in G_T} F_k(a_1, a_2, a_3) \sqrt{a_1 a_2 a_3}. \quad (20)$$

It follows from the results of Ustinov [46] that

$$A_1(T) \to \frac{8}{\pi} \text{ as } T \to \infty. \quad (21)$$

For the case $k > 1$ the upper bound in Theorem 1.1 of [3], together with (21) implies that for any $\epsilon > 0$ for large enough $T$

$$A_k(T) \leq \frac{8}{\pi} + \sqrt{2(k-1)} + \epsilon. \quad (22)$$

On the other hand, from the lower bound in Theorem 1.1 of [24] and the proof of Proposition 1 in [5] we conclude that for large enough $T$

$$A_k(T) > \sqrt{2k} - \epsilon. \quad (23)$$

In our experiments we empirically obtained the values for $A_k(T_0)$ for fixed $T_0$ and various values of $k$. For instance, for $T_0 = 3000$ we have drawn 2000 triples of coefficients in the range $[2, T_0]$. For each triple, we have computed the $k$-Frobenius number for $k = 10000, 30000, 60000, 100000, 150000$. In Figure 1, we represent, with a logarithmic scale, the product $a_1 a_2 a_3$ on the $x$-axis and the $k$-Frobenius on the $y$-axis for the respective values of $k$. In order to assess an approximate value for $A_k(T_0)$ we now perform a linear regression over $\log(a_1 a_2 a_3)$ and $\log(F_k(a_1, a_2, a_3))$ whose results are shown in the following table.

| Dimension $n = 10$ |
|---------------------|
| $k$     | 1 | 4 | 16 | 64 | 256 | 1024 | $2^{14}$ | $2^{16}$ |
| Average time (s) | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 |

Table 1. Dependency on $k$
Fig. 1. Value of the $k$-Frobenius (over the $y$-axis) with respect to the product $a_1a_2a_3$ for $a_i \in [2, 3000]$ for $k = 10000, 30000, 60000, 100000, 150000$.

| $k$    | $A_k(T_0)$ | $\sqrt{2k}$ |
|--------|------------|--------------|
| 10000  | 141.5535   | 141.4214     |
| 30000  | 245.0937   | 244.9490     |
| 60000  | 346.5570   | 346.4102     |
| 100000 | 447.3675   | 447.2136     |
| 150000 | 547.8815   | 547.7226     |

The obtained computational results allow us to make the following conjecture:

**Conjecture:** Let $G_T = \{a = (a_1, a_2, a_3) \in \mathbb{Z}_{>0}^3 : \gcd(a_1, a_2, a_3) = 1, ||a||_{\infty} \leq T\}$ and let $A_k(T)$ denote the average value of the (normalized) $k$-Frobenius number over $G_T$. Then

$$\limsup_{k} |A_k(T) - \sqrt{2k}| \to 0 \quad \text{as} \quad T \to \infty,$$

that is $A_k(T)$ asymptotically approaches the term $\sqrt{2k}$ of its lower bound $[22]$.

10 Acknowledgements

We are truly grateful to Lenny Fukshansky, Martin Henk, and Matthias Köppe for their comments, encouragement and corrections that improve the paper we present today. Some of our results were announced in [8].
