Symmetry of the superconducting order parameter in frustrated systems determined by the spatial anisotropy of spin correlations

B. J. Powell and Ross H. McKenzie
Department of Physics, University of Queensland, Brisbane, Queensland 4072, Australia

We study the resonating valence bond (RVB) theory of the Hubbard-Heisenberg model on the half-filled anisotropic triangular lattice (ATL). Varying the frustration changes the wavevector of maximum spin correlation in the Mott insulating phase. This, in turn, changes the symmetry of the superconducting state, that occurs at the boundary of the Mott insulating phase. We propose that this physics is realised in several families of quasi-two-dimensional organic superconductors.

PACS numbers:

One of the major themes in condensed matter physics over the last few decades has been the deep connection between magnetism and unconventional superconductivity. This is one of the key ideas that has emerged from the study of the cuprates [1], ruthenates [2], cobaltates [3, 4], heavy fermions [5], organic superconductors [6, 33He [7], and ferromagnetic superconductors [8]. In the cuprates $d_{x^2-y^2}$ symmetry superconductivity emerges from the doping of a Mott insulator with Néel order. Many theories [1, 3, 10, 11], including RVB, suggest that in the metallic state spin correlations which are maximal near the wavevector $(\pi, \pi)$ mediate superconductivity. In RVB theory [3, 4] superconductivity arises from the same strong correlations that give rise to antiferromagnetism in the Mott insulator. Alternative theories of the cuprates emphasize instead the role of different physics, such as stripes, phase fluctuations, or orbital currents [11].

When frustration is introduced into a system the insulating state may not be Néel ordered and the spin correlations may not be strongest at $(\pi, \pi)$. Therefore, a natural question to ask is what kinds of superconducting states do we expect to find when the spin correlations are different from the commensurate $(\pi, \pi)$ correlations? In this Letter we study an RVB theory of the Hubbard-Heisenberg model on the half filled ATL to investigate this question. This is partially motivated by the fact that this model may describe whole families of organic superconductors [4]. We find that as we vary the frustration in our model the peak in the spin fluctuations in the insulating state moves continuously from $(\pi, \pi)$ characteristic of weakly coupled chains (see Fig. 2). The spin correlations cause changes in the symmetry of the superconducting state, which changes from 'd$_{x^2-y^2}$' ($A_2$) for small $t'/t$ to 'd + id' ($A_1 + ia2$) for $t' \sim t$ to 's + d$_{xy}$' ($A_1$) for large $t'/t$.

![FIG. 1: (Color online.) Phase diagram of the Hubbard-Heisenberg model on the half filled ATL. As the frustration, $J'/J = (t'/t)^2$, is varied the spin correlations change from commensurate $(\pi, \pi)$ characteristic of the square lattice for $t'/t < 0.93$, to incommensurate $(q, q)$ in the highly frustrated regime, to commensurate ($\pi/2, \pi/2$) for $t'/t > 1.3$ characteristic of weakly coupled chains (see Fig. 2). The spin correlations mediate superconductivity, and the changes in the spin correlations cause changes in the symmetry of the superconducting state, which changes from 'd$_{x^2-y^2}$' ($A_2$) for small $t'/t$ to 'd + id' ($A_1 + ia2$) for $t' \sim t$ to 's + d$_{xy}$' ($A_1$) for large $t'/t$.](image-url)
\[ \Delta_k = \sum_{k'} V_{k-k'}^\dagger \langle \hat{c}_{k'}^\dagger \hat{c}_{-k'} \rangle, \]

where \( \hat{c}_{k}\) is the Fourier transform of \( \hat{c}_{\mathbf{r}} \), and \( d \) is the fraction of doubly occupied sites. The pairing interaction, \( V_k = -6(1 - 2d)^2 [J(\cos k_x + \cos k_y) + J' \cos(k_x + k_y)] \), arises from superexchange between nearest neighbours along the square (first term) and along one diagonal (second term), see Fig. \( \text{2} \). This potential directly links the symmetry of the superconductivity with the magnetic degrees of freedom. We assume singlet superconductivity. It then follows from the functional form of \( V_k \) and basic trigonometry that the mean fields may be written as \( \Delta_k = \Delta_0 \cos k_x + \Delta_y \cos k_y + \Delta_d \cos(k_x + k_y) \) and \( \chi_k = \chi_x \cos k_x + \chi_y \cos k_y + \chi_d \cos(k_x + k_y) - \tilde{\mu} \), the renormalised chemical potential \( \tilde{\mu} \) ensures half-filling. The symmetry of the ATL is represented by the group \( C_{2h} \).

A basic theorem of quantum mechanics is that the eigenstates must transform like an irreducible representation of group which represents the symmetry of the Hamiltonian. It follows from this requirement that \( |\Delta_x| = |\Delta_y|, \chi_x^2 = \chi_y^2, \) and \( \theta = \arg \Delta_x = -\arg \Delta_y \). Thus \( \Delta_k = |\Delta_x| \cos \theta \cos(k_x + k_y) + |\Delta_y| \cos(k_x + k_y) + i |\Delta_x| \sin \theta \cos(k_x + k_y) \).

For simplicity we only consider Mott insulating states that are spin liquids, i.e., do not possess long-range magnetic order. We are aware that for some parameters, e.g., large \( U/t \) and small \( t'/t \), that states with magnetic order may have slightly lower energy. However, the d-wave spin liquid states considered here are quite competitive in energy \(^1\) \(^2\) \(^3\) \(^4\). Further, other work shows that the instability of such ordered states to superconductivity, as \( U/t \) decreases, occurs for similar parameters as for spin liquid states. Hence, we suggest this simplifying assumption will not change our main results relating the superconducting symmetry to the spatial anisotropy of the spin correlations in the parent Mott insulator.

Within the Gutzwiller approximation, \( d = 0 \) in the insulating phase and the model is equivalent to the Heisenberg model. Therefore, results in the insulating phase do not explicitly depend on \( U \). However, in the insulating state the Hubbard model over-represents the Heisenberg model. This leads to an \( SU(2) \) degeneracy of the insulating phase of the RVB theory \(^1\) \(^2\). Physically this means that in the Mott insulator the mean fields are not physically distinct and the physical order parameters are \( D = \sqrt{\Delta_0^2 + \chi_x^2} = \sqrt{\Delta_0^2 + \chi_y^2} \) and \( D' = \sqrt{\Delta_0^2 + \chi_d^2} \). It is straightforward to show that the spin correlations are peaked at the wavevector \( (q, q) \) where \( q = \arccos (D'/2D^2) \). We solve the variational problem numerically on an \( 1000 \times 1000 \) k-space mesh. Fig. \( \text{2} \) compares the wavevector found in this way from the RVB theory with the classical result, \( q = \arccos \left( J/2J' \right) \) \(^6\). For \( J'/J < 0.87 \) \((t'/t < 0.93)\) we find that the spin correlations are commensurate and peaked at \((\pi, \pi)\), consistent with a tendency towards Néel ordering. We also find commensurate spin correlations [peaked at \((\pi/2, \pi/2)\)] for large \( J'/J \). This is the classical ordering wavevector for uncoupled chains. It is difficult to determine exactly when the correlations becomes commensurate, as there is a smooth crossover (see Fig. \( \text{2} \)). However, it is clear that \( q \sim \pi/2 \) for \( J'/J \gtrsim 1.7 \) \((t'/t \gtrsim 1.3)\). This shows that quantum effects enhance the stability of the region with commensurate spin correlations compared to the classical result. This effect is also found by other theoretical methods \(^17\). In the region \( 0.87 < J'/J \lesssim 1.7 \) \((0.93 < t'/t \lesssim 1.3)\) the insulating state is characterised by incommensurate spin correlations (except at the high symmetry point \( t' = t \), see below). In the metallic phase the two mean fields are physically distinct. \( \chi_k \) varies smoothly as the frustration, \( t'/t \) is varied (Fig. \( \text{3} \), but, three distinct superconducting phases are observed as is indicated by the behaviour of \( \Delta_k \) (Figs. \( \text{2} \) \( \text{3} \) and \( \text{4} \)).

For small \( t'/t \) we find that \( \Delta_d = 0 \) and \( \theta = -\pi/2 \), thus \( \Delta_k = \Delta_x \cos k_x - \cos k_y \). This is the prototypical form for a ‘\( d_{x^2-y^2} \)’ superconductor. Formally, \( \Delta_k \) transforms according to the \( A_2 \) representation of \( C_{2v} \). This is consistent with the fact that for small \( t'/t \) the spin correlations in the insulating state are peaked at \((\pi, \pi)\) (c.f., Fig. \( \text{2} \)).

For large \( t'/t \) we find that \( \Delta_x, \Delta_y, \Delta_d \neq 0 \) and \( \theta = -\pi/2 \). Thus the order parameter takes the form \( \Delta_k = |\Delta_k| \left( \cos k_x + \cos k_y \right) + i |\Delta_d| \left( \cos k_y - \sin k_x \sin k_y \right) \). The first three terms are usually referred to as ‘extended \( s(xs) \)’ order parameters as they transform according to the trivial representation, but may have accidental nodes.
However, the fourth term would be referred to as a ‘d_{xy}’ state on the square lattice. On the square lattice these ‘xs’ and ‘d_{xy}’ states belong to different irreducible representations of C_{4v}. We therefore refer to this state as the ‘s + d_{xy}’ state. However, we stress that \( \Delta_k \) transforms solely as the A_{1} representation of C_{4v}, a direct consequence of the lower symmetry of the ATL. In this regime the spin correlations are (nearly) commensurate at \((\pi/2, \pi/2)\), as expected for weakly coupled chains. Thus it is these q_{1d} correlations that cause the superconductor to take ‘s + d_{xy}’ symmetry.

For \( t' \sim t; \Delta_x, \Delta_y, \Delta_d \neq 0 \) and \(-\pi < \theta < -\pi/2\). Thus \( \Delta_k \) has a non-trivial complex phase and breaks time reversal symmetry (TRS): this might be detected by muon spin relaxation experiments \([19, 20]\). The real part is the same as \( \Delta_k \) for large \( t'/t \) and transforms according to the A_{1} representation. The imaginary part takes the same form as \( \Delta_k \) for small \( t'/t \) and transforms according to the A_{2} representation. We therefore refer to this state either as the \( A_1 + iA_2 \) or ‘d + id’ state. In this regime we have competition between spin correlations characteristic of the square lattice, which promote ‘d_{z^2-r^2}’ superconductivity, and those along the diagonal which favour a ‘s + d_{xy}’ state. The compromise between these frustrated interactions is the \( A_1 + iA_2 \) state with broken TRS. Fig. 3 details how \( \Delta_k \) varies with the frustration for \( t' \sim t \).

Exactly at \( t' = t \) the lattice becomes hexagonal and has C_{6v} symmetry. In the insulating phase we find commensurate spin fluctuations peaked at \((2\pi/3, 2\pi/3)\). In the superconducting state ‘xs’ terms transform like the \( A_1 \) representation of C_{6v}. However, the ‘d_{z^2-r^2}’ and ‘d_{xy}’ terms transform as the \( E_2 \) representation. \( E_2 \) is a two-dimensional representation spanned by the ‘d_{z^2-r^2}’ and ‘d_{xy}’ terms. Thus, ‘d + id’ states that transform as the \( E_2 \) representation are expected on symmetry grounds on the hexagonal lattice for appropriate values of the Ginzburg-Landau coefficients \([18, 19]\). This has already led to the prediction of broken TRS in \( \kappa-(ET)_{2}\text{Cu}_2(\text{CN})_3 \) and \( \beta'-(\text{Pd}(\text{dmit})_2)_{2}\text{X} \) on phenomenological grounds \([19]\). For \( t' \sim 0 \) the lattice is slightly distorted away from C_{6v} symmetry and this leads to either the ‘d_{z^2-r^2}’ (for \( t' \lesssim 0 \)) or ‘s + d_{xy}’ (for \( t' \gtrsim 0 \)) component giving a greater contribution to \( \Delta_k \). This is clearly seen in Figs. 2 and 3.

Experiments on Cs_{2}CuCl\_3 \([21]\) and other calculations \([17]\) suggest that RVB underestimates the size of the region where \( 0 < t' \approx 2\pi/3 \). As these frustrated spin fluctuations drive \( A_1 + iA_2 \) superconductivity this suggests that RVB theory may underestimate the stability of this phase and the size of the region of the phase diagram (Fig. 1) where \( A_1 + iA_2 \) superconductivity occurs.

We note that our phase diagram (Fig. 1) differs in the region around \( t' \sim t \), from that recently proposed by others \([22]\). These differences arise because those works did not consider the possibility of insulating states with incommensurate spin correlations or ‘d + id’ superconducting states, and so found a spin liquid state (with commensurate spin correlations) for \( t' \sim t \) and large \( U/t \).

There is significant evidence that RVB physics is enhanced on frustrated lattices \([6, 23]\) and that it is relevant to layered organic superconductors \([6, 14, 22]\). Further, the RVB theory predicts a pseudogap in the metallic state above the superconducting critical temperature. Below about 50 K such a pseudogap is suggested by NMR relaxation rate and Knight shift data \([6, 25]\). Additionally the insulating state of \( \kappa-(ET)_{2}\text{Cu}_2(\text{CN})_3 \) is a spin liquid \([6, 24]\). Thus these materials provide an testing ground for the ideas presented here. The band structures suggest that these materials span the parameter range where the different superconducting order parameters occur \([6]\). For example, \( t' < t \) in \( \kappa-(ET)_{2}\text{Cu}[\text{N(CN)}_2]\text{Cl} \) and \( \kappa-(ET)_{2}\text{Cu}[\text{N(CN)}_2]\text{Br} \) which suggests that they have ‘d_{z^2-r^2}’ \((A_2)\) order parameters, \( t' \sim t \) in \( \kappa-(ET)_{2}\text{Cu}_2(\text{CN})_3 \) and \( \beta'-(\text{Pd}(\text{dmit})_2)_{2}\text{X} \) and we propose that they have ‘d + id’ \((A_1 + iA_2)\) order parameters, and \( t' > t \) in \( \beta'-(\text{ET})_{2}\text{I}_3 \) which suggests that it has an ‘s + d_{xy}’ \((A_1)\) order parameter \([6]\). These results are consistent with our current knowledge of the superconducting states of these materials, but much controversy remains over the experimental situation \([6, 19]\). It has also been argued that the superconducting state of the doped triangular lattice compound Na_{2}CoO\_2 · yH\_2O is an RVB state with ‘d + id’ pairing \([2, 3]\). Ferromagnetic fluctuations are strong in doped triangular lattice systems \([26]\) and so the possibility of triplet superconductivity needs to be considered carefully in both doped and half-filled systems \([7]\).

We have studied the RVB theory of the Hubbard-Heisenberg model on the ATL. Varying the frustration \( t'/t \) changes the spatial anisotropy of the spin correlations, which vary from being peaked on \((\pi, \pi)\) for small
\[ t'/t, \text{ to incommensurate fluctuations for } t' \sim t \] except at \( t' = t \) where the \((3\pi/2, 3\pi/2)\) fluctuations are commensurate, to being commensurate at \((\pi/2, \pi/2)\) for large \( t'/t \). This drives changes in the symmetry of the superconducting state. We propose that, as \('d_{x^2-y^2}\') results from proximity to a Néel ordered state, so \('d + id'\) superconductivity arises from proximity to a spiral state and \('s + id_{xy}\)' superconductivity is driven by q1d spin fluctuations. The generality of the connection between \((\pi, \pi)\) spin correlations \[ \frac{1}{2} \left( \frac{J}{t} - 1 \right) \text{ suggests that our results are valid beyond the Hamiltonian studied and the approximations used in this Letter. This clearly begs the question: which superconducting states are driven by proximity to other magnetic orderings?} \]

We thank J. Barjaktarevic, R. Coldea, J. Fjærestad, J. Merino, R. Singh, S. Sorella, and E. Yusuf for stimulating conversations. This work was funded by the ARC.

[12] In principle \( J = 4t^2/U \) and \( J' = 4t'^2/U \). Our mean-field treatment does not fully capture the renormalisation of the bare parameters. Thus, we fix \( J = t/3 \) and \( J' = t'/3t \), which correspond roughly to the values of \( J \) and \( J' \) extracted from experiments on the insulating phase of the layered organics \[ \text{[12]} \] and ensures that \( J'/J = (t'/t)^2 \).
