Non-perturbative evaluation of some QED contributions to the muonic hydrogen $n = 2$ Lamb shift and hyperfine structure

P. Indelicato

Laboratoire Kastler Brossel, École Normale Supérieure; CNRS; Université Pierre et Marie Curie - Paris 6; 4, place Jussieu, 75252 Paris CEDEX 05, France
(Dated: November 1st, 2012)

The largest contributions to the $n = 2$ Lamb-shift, fine structure interval and 2S hyperfine structure of muonic hydrogen are calculated by exact numerical evaluations of the Dirac equation, rather than by a perturbation expansion in powers of $1/c$, in the framework of non-relativistic quantum electrodynamics. Previous calculations and the validity of the perturbation expansion for light elements are confirmed. The dependence of the various effects on the nuclear size and model are studied.

PACS numbers: 31.30.jf,36.10.Ee,31.30.Gs

Despite many years of study, the proton charge radius has remained relatively poorly known. It has been derived from measurements in electron-proton collisions [1, 2] or from high-precision spectroscopy of hydrogen [3–10] as described in the CODATA report in [11]. Tests of fundamental physics based on the progress in accuracy of spectroscopy of hydrogen and deuterium have been limited by the lack of an accurate value for the proton radius. Moreover, the values for the proton radius obtained by different methods or different analyses of existing experiments are spread over a range larger than the uncertainty quoted for the individual results. Two recent measurements have resulted in a puzzle. The accurate determination of the 2S Lamb shift by laser spectroscopy in muonic hydrogen provides a proton size with a ten times smaller uncertainty than any previous value and it differs by five standard deviations from the 2006 CODATA value [12]. At the same time, a new, improved determination of the charge radius by electron scattering, performed at Mainz with the MAMI microtron, provides a value in good agreement with the value from hydrogen and deuterium spectroscopy [13, 14]. Taking into account improved theory in hydrogen and deuterium and the MAMI measurement lead the recently released 2010 adjustment [15] to differ by 6.9 standard deviation between from the proton radius obtained from muonic hydrogen.

Many papers have been published in the last year, trying to solve this puzzle. A few are dealing with the calculation of the $n = 2$ level energies in muonic hydrogen. Several others are concerned with the effect of the internal structure of the proton on these energies [16–27]. Others look at exotic phenomenon beyond the standard model [28–34].

Many contributions to the Lamb shift, fine, and hyperfine structure of muonic hydrogen have been evaluated over the years; the results are summarized in [35–40] and in a recent book by Eides et al. [41]. Most of these calculations are done in the framework of nonrelativistic QED. The wavefunction and operators are expanded in powers of the fine-structure constant, and the contributions are obtained by perturbation theory. Hylton [42] showed that the perturbation calculation of the finite size correction to the vacuum polarization in heavy elements gives incorrect results. Since a bound muon is closer to the nucleus than a bound electron by a factor $m_\mu/m_e \approx 207$, its Bohr radius is slightly smaller than the Compton wavelength of the electron $\lambda_C = h/m_e c$ by a factor $m_\mu/\alpha m_e \approx 137/207 (\alpha \approx 1/137.036$ is the fine structure constant, $m_e$ and $m_\mu$ the electron and muon mass respectively). The Compton wavelength is the scale of QED corrections, and for the 2S level, the muon wavefunction mean radius is only 2.6 times larger than the electron Compton wavelength.

It is thus worthwhile to reconsider the largest corrections that contribute to the 2S Lamb-shift in muonic hydrogen using non-perturbative methods. In the present work, we use the latest version of the MCDF code of Desclaux and Indelicato [43], which is designed to calculate properties of exotic atoms [44], to evaluate the exact contribution of the electron Uehling potential with Dirac wavefunctions including the finite nuclear size. In the same way, we calculate the Källén and Sabry contribution.

Throughout this paper we will use QED units, $h = 1$, $c = 1$. The electric charge is given by $e^2 = 4\pi\alpha$.

I. NUMERICAL EVALUATION OF THE DIRAC EQUATION WITH REALISTIC NUCLEAR CHARGE DISTRIBUTION MODELS

A. Evaluation by the numerical solution of the Dirac equation

We calculate higher-order finite size correction, starting from the Dirac equation with reduced mass, as techniques for the accurate numerical solution of the Dirac equation in a Coulomb potential have been developed over a period of many years within the framework of the Multiconfiguration Dirac-Fock (MCDF) method for the
atomic many-body problem [45–48].

The Dirac equation is written as

\[ \left[ \alpha \cdot p + \beta \mu_e + V_N(r) \right] \Phi_{\text{nuc}}(r) = \mathcal{E}_{\text{nuc}} \Phi_{\text{nuc}}(r), \]

(1)

where \( \alpha \) and \( \beta \) are the Dirac 4 × 4 matrices, \( V_N(r) \) is the Coulomb potential of the nucleus, \( \mathcal{E}_{\text{nuc}} \) is the atom total energy, and \( \Phi \) is a one-electron Dirac four-component spinor:

\[ \Phi_{\text{nuc}}(r) = \frac{1}{r} \left[ \begin{array}{c} P_n(r) \chi_{\kappa}(\theta, \phi) \\ i Q_n(r) \chi_{-\kappa}(\theta, \phi) \end{array} \right], \]

(2)

in which \( \chi_{\kappa}(\theta, \phi) \) is the two-component Pauli spherical spinor [46], \( n \) is the principal quantum number, \( \kappa \) is the Dirac quantum number, and \( \mu \) is the eigenvalue of \( I_y \). This reduces, for a spherically symmetric potential, to the differential equation:

\[ \begin{bmatrix} V_N(r) - \frac{4}{r} \frac{d}{dr} \frac{1}{r} & P_{\text{me}}(r) \\ \frac{4}{r} \frac{d}{dr} \frac{1}{r} & V_N(r) - 2\mu_e \end{bmatrix} \begin{bmatrix} P_{\text{me}}(r) \\ Q_{\text{me}}(r) \end{bmatrix} = \mathcal{E}_{\text{nuc}} \begin{bmatrix} P_{\text{me}}(r) \\ Q_{\text{me}}(r) \end{bmatrix}, \]

(3)

where \( P_{\text{me}}(r) \) and \( Q_{\text{me}}(r) \) are the large and small radial components of the wavefunction, respectively, \( \kappa \) the Dirac quantum number, \( \mathcal{E}_{\text{nuc}} \) the binding energy, \( \mu_e \) is the muon reduced mass, \( \mu_r = m_u M_p/(m_u + M_p) \) (\( m_u \) and \( M_p \) are the muon and proton masses).

To solve this equation numerically, we use a 5 point predictor-corrector method (order \( h^7 \)) [48, 49] on a linear mesh defined as

\[ t_n = \ln(\frac{r_n}{r_0}) + ar_n, \]

(4)

with \( t_n = t_0 + nh \) and \( r_0 > 0 \) is the first point of the mesh, corresponding to \( n = 0 \). This immediately gives \( t_0 = 0 \). Equation (4) can be inverted to yield

\[ r_n = \frac{W(a r_0 e^{t_n})}{a}, \]

\[ \frac{dr_n}{dt_n} = \frac{W(a r_0 e^{t_n})}{a [1 + W(a r_0 e^{t_n})]^2}, \]

(5)

where \( W \) is the Lambert (or product logarithm) function. The wavefunction and differential equation between 0 and \( r_0 \) are represented by a 10 term series expansion. For a point nucleus, the first point is usually given by \( r_0 = 10^{-2}/Z \) and \( h = 0.025 \). Here we use values down to \( r_0 = 10^{-7}/Z \) and \( h = 0.002 \) to obtain the best possible accuracy. For a finite charge distribution, the nuclear boundary is fixed at the value \( r_N \), where \( N \) is large enough to obtain sufficient accuracy. The mean value of an operator \( O \), that gives the first-order contributions to the energy, is calculated as

\[ \Delta E_O = \int_0^\infty dr \left[ P(r)^2 + Q(r)^2 \right] O(r) \]

\[ = \int_0^{r_N} dr \left[ P(r)^2 + Q(r)^2 \right] O(r) + \int_{r_N}^\infty \frac{dr}{dr} \left[ P(r)^2 + Q(r)^2 \right] O(r) \]

(6)

using 8 and 14 points integration formulas due to Roothan. The two integration formulas provide the same result within 9 decimal places.

B. Charge distribution models

For the proton charge distribution, two models are extensively used. The first corresponds to a proton dipole (charge) form factor, the second is a gaussian model. Here we also use uniform and Fermi charge distributions and fits to experimental data [50, 51]. The analytic distributions are parametrized so they provide the same mean square radius \( R \). Moments of the charge distribution are defined by

\[ < r^n > := 4\pi \int_0^\infty r^{2+n} \rho(r) dr, \]

(7)

where the nuclear charge distribution \( \rho(r) = \rho_N(r)/(Ze) \) is normalized by

\[ \int \rho(r) dr = 4\pi \int_0^\infty \rho(r) r^2 dr = 1, \]

(8)

for a spherically symmetric charge distribution. The mean square radius is \( R = \sqrt{< r^2 >} \).

The potential can be deduced from the charge density using the well known expression:

\[ V_N(r) = -4\pi e^2 \int_0^\infty du u^2 \rho_N(u) - 4\pi e^2 \int_0^\infty du u \rho_N(u). \]

(9)

The exponential charge distribution and corresponding potential energy are written

\[ \rho_N(r) = Z e^{\frac{e^{-r}}{8\pi \xi^3}}, \]

\[ V_N(r) = -Z e^2 \left( \frac{1 - e^{-r}}{r} - \frac{e^{-r}}{2\xi} \right), \]

(10)

where \( \xi = \frac{\xi}{2\sqrt{3}} \). The gaussian charge distribution and potential are given by

\[ \rho_N(r) = Z e^{-r^2/(\pi\xi^2)}, \]

\[ V_N(r) = -Z e^2 \text{erf} \left( \frac{r}{\sqrt{3}\xi} \right), \]

\[ < r^n > = \frac{(n + 2)!}{2} \xi^n, \]

(11)

which gives \( \xi = \frac{\xi}{2\sqrt{3}} \). Other similar expressions for the two above models can be found in [52].
The electric form factor is related to the charge distribution by

\[ G_E(Q^2) = \int dr e^{-iq\cdot r} \rho(r), \quad (12) \]

For the exponential model this leads to

\[ G_E(Q^2) = \frac{1}{(1 + R_0^2q^2)} \approx 1 - \frac{R^2}{6} q^2 + \frac{R^4}{48} q^4 + \cdots \quad (13) \]

while for the Gaussian model one has

\[ G_E(Q^2) = e^{-iR_0q^2} \approx 1 - \frac{R^2}{6} q^2 + \frac{R^4}{72} q^4 + \cdots \quad (14) \]

The two models have an identical slope \( R^2/6 \) as functions of \( q^2 \) for \( q \to 0 \) as expected (see, e.g., [53]).

In 1956, Zemach introduced an electromagnetic form factor, useful for evaluating the hyperfine structure energy correction

\[ \rho_{em}(r) = \int \rho(r - u)\mu(u)du, \quad (15) \]

where \( \mu(u) \) is the magnetic moment density. Both \( \mu(u) \) and \( \rho_{em} \) are normalized to unity as in Eq. (8). The Zemach radius is given by

\[ R_Z = \langle r_Z \rangle = \int r \rho_{em}(r)dr. \quad (16) \]

The Zemach’s radius can be written in momentum space as [54, 55]

\[ R_Z = \frac{-4}{\pi} \int dq \frac{1}{q^2} \left( G_E(Q^2) \frac{G_M(Q^2)}{1 + \kappa_p} - 1 \right), \quad (17) \]

where \( \kappa_p \) is the proton anomalous magnetic moment, and \( G_M \) is normalized so that \( G_M(0) = 1 + \kappa_p \). The exponential and gaussian models enable to obtain analytic results for \( R_Z \) as a function of the charge and magnetic moment radii \( R \) and \( R_M \). Using (13) or (14) for the exponential or gaussian model, and Eq. (17), we get respectively

\[ R_Z^{\text{Exp}} = \frac{3R^4 + 9R^3R_M + 11R^2R^2_M + 9RR^3_M + 3R^4_M}{2\sqrt{3}(R + R_M)^3} \quad (18) \]

\[ R_Z^{\text{Gauss}} = 2\sqrt{\frac{2}{3\pi}} \sqrt{R^2 + R^2_M}. \quad (19) \]

An other useful quantity, which appears in the estimation of the finite size correction to vacuum polarization is the third Zemach’s moment

\[ \langle r^3 \rangle_{(2)} = \int r^3 \rho_{(2)}(r)dr, \quad (20) \]

where the convolved charge distribution is

\[ \rho_{(2)}(r) = \int \rho(r - u)\rho(u)du. \quad (21) \]

This can be rewritten in the more convenient form [17, 35], in the limit of large proton masses,

\[ \langle r^3 \rangle_{(2)} = \frac{48}{\pi} \int dq \frac{1}{q^2} \left( c^2_2 \langle \bar{Q}^2 \rangle - 1 + \frac{q^2}{3} R^2 \right). \quad (22) \]

It can be easily seen from Eqs. (13) or (14) that the expression is finite for \( q \to 0 \).

We now turn to more realistic models, based on experiment. A recent analysis of the world’s data on elastic electron-proton scattering and calculations of two-photon exchange effects provides an analytic expression for the electric form factors [51], given as

\[ G_E(Q^2) = \frac{1 + \sum_{\tau=1}^{2}\bar{a}_\tau |a_\tau|^2}{1 + \sum_{\tau=1}^{2}\bar{b}_\tau |b_\tau|^2}, \quad (23) \]

where \( \tau = \sqrt{q^2/(4M_p)} \). The \( a_\tau \) coefficients can be found in Table I of Ref. [51]. A second work [50] uses a combination of several spectral functions taking into account several resonances and continua like the \( 2\pi, \, K\bar{K} \) and \( \pi\pi \) continua. Here we use the fit resulting from the super-convergence approach from this work. This corresponds to a sum of 12 dipole-like functions, which are able to represent the experimental data with a reduced \( \chi^2 \) of 1.8. A comparison of the electric form factor from both works is presented on Fig. 3. It is clear that both experimental form factors and the dipole approximation with an identical radius are very close. We can obtain the charge radius and the next correction by performing an expansion in \( q \) of the experimental form factors. We get for Ref. [51]

\[ G_E(Q^2) \approx 1 - \frac{0.8503^2}{6} q^2 + \frac{0.8503^4}{43.3909} q^4 + \cdots, \quad (24) \]
These expansions are very close to the one for a dipole form factors from Eq. (13).

In order to compare different charge density models, we have performed an analytic evaluation of the charge densities corresponding to [51], replacing (23) in (12) and performing the inverse Fourier transforms, to obtain the corresponding charge distribution, depending on the set of \( a \) coefficients. The corresponding densities are plotted and compared to Fermi, Gaussian and exponential models. Distances are converted from GeV to fm using \( \hbar c = 0.1973269631 \) GeVfm in the density obtained from the experiment. The charge distributions are compared on Fig. 2. We plotted both \( \rho(r) \) and \( r^2 \rho(r) \) to reveal the differences at long and medium distances. The experimental charge density is rather different from all three analytic distributions, while, once multiplied by \( r^2 \), it is closer to the exponential distribution.

![Diagram](image.png)

**FIG. 3.** Comparison of the electric form factor from Refs. [50, 51], with a dipole model with the same \( R = 0.850 \) fm as deduced from the experimental function.

![Diagram](image.png)

**FIG. 4.** Feynman diagrams corresponding to the full vacuum polarization contribution, and expansion in \( Z \alpha \). Diagram (a) corresponds to the Uehling potential [Eqs. (26) and (28)]. Diagram (b) corresponds to the Wichmann and Kroll correction. The double line represents a bound lepton wavefunction, the wavy line a retarded photon propagator. The single line correspond to a free electron-positron (or muon-antimuon) pair. The grey circles correspond to the interaction with the nucleus.

## II. EVALUATION OF MAIN VACUUM POLARIZATION AND FINITE SIZE CORRECTION

The Feynman diagram corresponding to the Uehling approximation to the vacuum polarization correction is presented in Fig. 4 (a). The evaluation of the vacuum polarization can be performed using standard techniques of (perturbative) non-relativistic QED (NRQED) as described in [35, 37]. Here we use the analytic results of Klarsfeld [56] as described in [57] and numerical solution of the Dirac equation from Sec. I. In order to obtain higher order effects, we solve the Dirac equation in a combined potential resulting from the finite nuclear charge distribution and of the Uehling potential. The logarithmic singularity of the Uehling potential at the origin for a point charge cannot be easily incorporated
in a numerical Dirac solver. In the case of a finite charge distributions, the singularity is milder, but great care must be exercised to obtain results accurate enough for our purpose.

For a point charge, the Uehling potential, which represents the leading contribution to the vacuum polarization, is expressed as [56, 58, 59]

\[
V_{11}^{\text{p}}(r) = -\frac{2\alpha(Za)}{3\pi} \int_1^{\infty} dz \sqrt{z^2 - 1} \left( \frac{2}{z^2} + \frac{1}{z^4} \right) e^{-2m_e z r} r
\]

(26)

where \( m_e \) is the electron mass, \( \lambda_e \) is the electron Compton wavelength and the function \( \chi_1 \) belongs to a family of functions defined by

\[
\chi_n(x) = \int_1^{\infty} dz e^{-xz} \left( \frac{1}{z^2} + \frac{1}{z^4} \right) \sqrt{z^2 - 1}.
\]

(27)

The expression of this potential is for a point charge, corresponding to the diagrams in Fig. 5. The Uehling potential for a spherically symmetric charge distribution is expressed as [56]

\[
V_{11}(r) = -\frac{2\alpha(Za)}{3} \int_0^{\infty} dr' r' \rho(r') \chi_1 \left( \frac{2}{\lambda_e} r \right)
\]

(28)

The expression of the potential at the origin is given by

\[
V_{11}(0) = -\frac{8\alpha(Za)}{3} \int_0^{\infty} dr' \rho(r') \chi_1 \left( \frac{2}{\lambda_e} r \right),
\]

(29)

while it behaves at large distances as [60]

\[
V_{11}(r) \sim -\frac{2\alpha(Za)}{3\pi} \frac{1}{r} \chi_1 \left( \frac{2}{\lambda_e} r \right) + \frac{2}{3} \left< r^2 > \chi_{-3} \left( \frac{2}{\lambda_e} r \right) + \ldots \right.
\]

(30)

using the moments of the charge distribution (7). The energy shift associated with the potential (26) or (28) in first order perturbation is calculated as

\[
\Delta E_{\text{link}}^{11,\text{p}} = \langle n, l, \kappa, \mu | V_{11} | n, l, \kappa, \mu \rangle
\]

(31)

where \( | n, l, \kappa, \mu \rangle \) is a wavefunction solution of Eq. (1), which depends on the reduced mass. It was shown recently [61] that this method provides the correct inclusion of the vacuum polarization recoil correction at the Barker and Glover level [62]. Since we directly use relativistic functions, the other corrections described in [61] are automatically included.

III. HIGHER ORDER QED CORRECTIONS

A. Reevaluation of the Källén and Sabry potential

The Källén and Sabry potential [63], is a fourth order potential, corresponding to the diagrams in Fig. 5. The expression for this potential has also been derived on Ref. [64-67]. In the previous version of the mdfsme code, the Källén and Sabry potential used was the one provided by Ref. [60], which is only accurate to 3 digits. The expression of this potential is for a point charge

\[
V_{21}(r) = \frac{\alpha^2(Za)}{\pi^2 r} L_1 \left( \frac{2}{\lambda_e} r \right),
\]

(32)

where

\[
L_1(r) = \int_1^{\infty} dt e^{-r} \left( \frac{2}{3t^4} - \frac{8}{3t} \right) f(t)
\]

(33)

\[
+ \left( \frac{2}{3t^4} + \frac{13}{5t^2} \right) \frac{1}{\sqrt{2}} \ln \left( \frac{3t}{(t - 1)} \right)
\]

\[
+ \frac{2}{9t^2} \left( \frac{5}{4t^2} + \frac{2}{3t^3} - \frac{44}{9t} \right) \ln \left( \sqrt{2} - 1 + t \right),
\]

(34)

The function \( f(t) \) can be calculated analytically in terms of the ln and dilogarithm functions. Blomqvist [68] has shown that \( L_1(r) \) can be expressed as

\[
L_1(r) = g_2(r) \ln^2(r) + g_3(r) \log(r) + g_0(r),
\]

(35)

and provided a series expansion of this function for small \( r \). Fullerton and Rinker [60] provided polynomial approximations to the functions \( g_i(r) \). Here we have numerically evaluated the function \( L_1(r) \) to a very good accuracy, using Mathematica. We then fitted the coefficients of polynomials for the function \( g_i(r) \). The results are presented in Appendix A. For \( x > 3 \), we have used the functional form

\[
L_1(r) = \frac{e^{-r} \left( a + b \sqrt{r} + cr + dr^{3/2} + er^2 + fr^{5/2} \right)}{r^{1/2}}
\]

(36)

FIG. 5. Feynman diagrams included in the Källén and Sabry potential (Eq. (32)). See Fig. 4 for explanation of symbols.
The coefficients are also given in Appendix A.

To obtain the finite nuclear size correction, we use the known expression for a spherically-symmetric charge distribution [60]

\[ V_{21}(r) = \frac{a^2(Za)}{πr^2} \int_0^\infty dr' r' \rho(r') \left( L_0 \left( \frac{2}{\lambda_e} r-r' \right) - L_0 \left( \frac{2}{\lambda_e} r-r' \right) \right), \]  

(37)

where

\[ L_0(x) = -\int_x^\infty du L_1(u). \]  

Using our approximation to \( L_1(x) \) in Eqs (35) and (36), we obtain the following approximate expressions for \( L_0(x) \).

For \( x \leq 3 \), the expression is very similar to the one for \( L_1(x) \). One obtains

\[ L_0(r) = rh_2(r) \ln^2(r) + rh_1(r) \log(r) + h_0(r), \]  

(39)

The expression for the functions \( h_i \) are given in Appendix B. For the asymptotic function, given for \( x > 3 \), we integrate directly Eq. (36), which yield (fixing the integration constant so that \( L_0(0) = 0 \) at infinity)

\[ L_0(r) = 41.1352787432251923 \]
\[- 5.109497759522696 \times 0.05074798111 \times \text{erf} \left( \sqrt{r} \right) \]
\[- 1.028091975364 \times \text{Ei}(-r) \]
\[ + \frac{e^{-r}}{r^{5/2}} \left( -2.02809197536 \times 3.3/2 + 4.54214815071 \times r^2 \right) \]
\[- 0.494718704003 \times 0.98439728916 \sqrt{r} \]
\[- 0.344009752879 \]  

where \( \text{Ei}(r) \) is the exponential integral.

IV. NUMERICAL RESULTS

A. Finite size correction to the Coulomb contribution

Obtaining the accuracy required from the calculation on \( E_{2p_{1/2}} \), which has a value of \( \approx 632.1 \text{ eV} \), while the Lamb shift is \( \approx 0.22 \text{ eV} \) with an aim at better than 0.001 meV, is a very demanding task. For a point nucleus, we get exact degeneracy for the \( 2s \) and \( 2p_{1/2} \) Dirac energies. The best numerical accuracy was obtained generating the wavefunction on a grid with \( r_0 = 2 \times 10^{-5} \) and \( h = 2 \times 10^{-3} \). This corresponds to \( \approx 8700 \) tabulation points for the wavefunction, with around 2800 points inside the proton. I checked that variations in \( r_0 \) and \( h \) do not change the final value. The main finite nuclear size effect on the \( 2p_{1/2}-2s \) energy separation comes from the sum of the Dirac energy splitting (the \( 2p_{1/2} \) and \( 2s \) level are exactly degenerate for a point nucleus).

I evaluated the different quantities on a grid of proton sizes ranging from 0.3 to 1.2 fm, with steps of 0.025 fm (80 points). I also evaluated the contribution for the muonic hydrogen proton size and the CODATA 2010 proton size. The first few terms of the dependence of the relativistic energy on the moments of the charge distribution where given by Friar [52]. For a Gaussian charge distribution he finds for a \( s \) state

\[ \Delta E_{\text{Coul}} = a(\rho^2) + b(\rho^3) + c(\rho^2)^2 + d(\rho^2)(\log \rho) + e(\rho^2)^2(\log \rho). \]  

(41)

I use this as a guide to fit my numerical results.

As a first example a 3-parameter fits provides

\[ \Delta E_{\text{Coul}}(2p_{1/2}-2s) = -5.199772 R^2 + 0.0351289 R^3 - 0.000534235 R^4 \text{ meV} \]  

(42)

A better fit is provided by

\[ \Delta E_{\text{Coul}}(2p_{1/2}-2s) = -5.19990 R^2 + 0.03559 R^3 \]
\[- 0.000488059 R^4 + 0.000172334 R^5 \]
\[- 0.000245051 R^6 \]  

Using Friar functional form with only one log \( R \) term, I obtain

\[ \Delta E_{\text{Coul}}(2p_{1/2}-2s) = -5.199365 R^2 + 0.0346610 R^3 \]
\[ + 0.0007366037 R^4 \]
\[- 0.000017296 R^5 + 1.198332 \times 10^{-6} R^6 \]
\[ + 0.000267736 R^2 \log R \text{ meV}. \]  

(44)

The function with two logarithmic terms and close values of the BIC and \( \chi^2 \) criteria is given by

\[ \Delta E_{\text{Coul}}(2p_{1/2}-2s) = -5.199337 R^2 \]
\[ + 0.03458139 R^3 + 0.000102985 R^4 \]
\[ + 0.000278838 R^2 \log R - 0.0000495795 R^4 \log R \]  

(45)

Criteria for the quality of the fit are plotted in Fig. 6. I use both the reduced \( \chi^2 \) and a Bayesian information criterion (BIC) to evaluate the improvement in the value when increasing the number of parameters [69]. We obtain a coefficient for \( R^2 \) which is \( -5.1999 \text{ meV/fm}^2 \) and a coefficient for \( R^3 \) equal to \( 0.03559 \text{ meV/fm}^3 \). Using our numerical solutions we also find \( -5.1972 \text{ meV/fm}^2 \) and 0.032908 meV/fm^2 for the Gaussian model. Borie [39] finds \( -5.1975 \text{ meV/fm}^2 \) and 0.0347 meV/fm^2 for an exponential model, and 0.0317 meV/fm^2 for a Gaussian model, in reasonable agreement with the result presented here.
The constant term is in perfect agreement with Borie’s value 8.41564 meV [70] (Table 7).

It is interesting to explore at this stage the influence of the charge distribution shape on the Coulomb and vacuum polarization contribution. Friar and Sick [71] have evaluated the third Zemach moment from Eq. (20), using the proton-electron scattering data available in 2005. Using a model-independent analysis, they find \( \langle r^3 \rangle = 2.71 \pm 0.13 \, \text{fm}^3 \), leading to an energy shift of \(-0.0247 \pm 0.0012 \, \text{meV}\). Using the Fourier transform of the exponential (13) distribution in Eq. (22), I find

\[
\langle r^3 \rangle = \frac{35 \sqrt{3} R^3}{16} \approx 3.789 R^3,
\]

showing that \( \langle r^3 \rangle \) is proportional to \( R^3 \) and justifying the fit in \( R^2 \) and \( R^3 \) performed to derive the coefficients above. Equation (47) is in exact agreement with the result that can be obtained from Eq. (15) in [16], but Eq. (16) in the same work is not correct (the denominator should be 256, not 64). The value obtained by Friar and Sick corresponds to \( R = 0.894 \, \text{fm} \). In that case our energy shift is \(-0.0250 \, \text{meV}\) in good agreement with the energy shift in Ref. [71]. In the Gaussian model, I find

\[
\langle r^3 \rangle = \frac{32 R^3}{3 \sqrt{3} \pi} \approx 1.960 R^3,
\]

leading to \( R = 0.920 \, \text{fm} \) and an energy shift of \(-0.0256 \, \text{meV}\), still in agreement. One can perform a more advanced calculation, using the experimental charge distribution from Ref. [51], as given in (23). I find \( \langle r^3 \rangle = 2.45 \, \text{fm}^3 \), significantly lower than Friar and Sick’s value. This lead to \( R = 0.864 \, \text{fm} \) for the exponential model and \( R = 0.889 \, \text{fm} \) for the Gaussian model, providing shifts of \(-0.0226 \, \text{meV} \) and \(-0.0232 \, \text{meV} \) respectively, in closer agreement to Borie’s work. In a recent paper, De Rújula [16] claims that the discrepancy found between the charge radii obtained from hydrogen and muonic hydrogen could be due to the fact that theoretical calculations use too simple a dipole model to represent the nucleus. He builds a “toy model” composed of the sum of two dipole function corresponding to two resonances with different masses. In his model the third moment of the charge distribution is much higher than what is derived from a dipole model, enabling to mostly resolve the discrepancy between charge radii obtained from muonic and normal hydrogen. He gets

\[
\langle r^3 \rangle = 36.6 \pm 7.3 \approx 43 R^3,
\]

using \( R \) from muonic hydrogen. I use the fit to the experimental form factor from Ref. [51] as given in Eq. (23) to check the result from Ref. [16] against an experimental determination. I obtain

\[
\langle r^3 \rangle \approx 2.4485 \approx 3.98 \times 0.850^3,
\]

very close to the dipole model value of Eq. (47). Using the recent MAMI experiment, combined with data from [51], Distler et al. [22] obtain

\[
\langle r^3 \rangle \approx 2.85(8) \approx 4.18 \times 0.880^3,
\]

The conclusions from Ref. [16], which depend on an overly large third moment of the charge distribution are thus not supported by experiment.

B. Finite size correction to the Uehling contribution

For the vacuum polarization we obtain, for a point nucleus,

\[
\Delta E^{\text{3nu}}_{2s_{1/2}-2p_{1/2}} = 205.028201 \, \text{meV},
\]

to be compared with 205.0282 meV in Ref. [39]. Fachucki [37] obtained 205.0243 meV as the sum of the non-relativistic 205.0074 meV and first order relativistic 0.0169 meV corrections. If I calculate the difference between (52) and Fachucki non-relativistic value, I obtain a
difference of 0.0208076 meV. This is in excellent agreement with the value provided in Ref. [72], Eq. (6), 0.020843 meV.

To achieve this result we used the mesh parameters described in the previous section, and checked by varying them so that the results were stable within the decimal places provided here. For finite nuclei, I use the same parameters as in the previous section. Again changes in \( r_0 \) and \( h \) do not change the final value. We get

\[
\Delta E_{2s_{1/2} - 2p_{1/2}}^{11,fs} (R) = 205.0282076 - 5.227446248 R^2
+ 0.03529257801 R^3 \\
- 1.1662334 \times 10^{-7} R^2
+ 2.2741334 \times 10^{-9} R^3 \\
- 1.5308196 \times 10^{-10} R^4 \text{ meV},
\]

where the constant term is in agreement with the one in Ref. [72] Table III, which has the value 0.52254 meVfmeV, which contains additional recoil corrections.

For the Uehling correction to the fine structure, I obtain in the same way:

\[
\Delta E_{2p_{1/2} - 2p_{3/2}}^{11,fs} (R) = 0.0050157881 \\
- \frac{1.1662334 \times 10^{-7}}{2} R^2
+ \frac{2.2741334 \times 10^{-9}}{2} R^3 \\
- \frac{1.5308196 \times 10^{-10}}{2} R^4 \text{ meV},
\]

C. Finite size correction to the Källén and Sabry contribution

We can then evaluate the Källén and Sabry contribution \( \Delta E_{2s_{1/2} - 2p_{1/2}}^{21,fs} \), using \( V_{21} \) calculated following Sec. IIIA, with good accuracy, using our numerical wavefunctions. For a point nucleus I obtain

\[
\Delta E_{2s_{1/2} - 2p_{1/2}}^{21,fs} = 1.508097 \text{ meV},
\]

which is in agreement with the result of Ref. [37], 1.5079 meV, and in excellent agreement with the one from Ref. [39], 1.5081 meV. Using the wavefunctions calculated with the proton size, I can also evaluate the finite size correction to the Källén and Sabry contribution. A direct fit to the numerical data gives a result of the form

\[
\Delta E_{2s_{1/2} - 2p_{1/2}}^{21,fs} (R) = 1.508097 - 0.0002134129 R^2 \\
+ 7.3404895 \times 10^{-6} R^3 \\
- 5.0291143 \times 10^{-7} R^4 \text{ meV},
\]

and

\[
\Delta E_{2p_{1/2} - 2p_{3/2}}^{21,fs} (R) = 0.0000414300 - 9.25489 \times 10^{-10} R^2 \\
+ 2.33622 \times 10^{-11} R^3 \\
- 1.80063 \times 10^{-12} R^4 \text{ meV},
\]

for the fine structure, to be compared with 0.00004 meV in Ref. [70].

V. HIGHER-ORDER VACUUM POLARIZATION CORRECTIONS

A. Higher-order vacuum polarization

The term named “VP iteration”, which correspond to Fig. 7, is given by Eq. (215) of Ref. [38]

\[
\Delta E_{VP VP}(2s) = 0.01244 \frac{\mu_e}{(Za)^2} \text{ meV}
\]

where \( \mu_e = 9.64446 \text{ MeV} \) for muonic hydrogen (using [11]). This adds 0.15086 meV to the Lamb-shift for muonic hydrogen. The Uehling potential under the form used in Sec. II can be introduced in the potential of the Dirac equation (3) when solving it numerically. This amounts to get the exact solution with any number of vacuum polarization insertions as shown in Fig. 7. The numerical methods that we used are described in Ref. [56, 57]. Because of the Logarithmic dependence of the point nucleus Uehling potential at the origin, we do not calculate the iterated vacuum polarization directly for point nuclei. We instead calculate for different mean square radii and charge distribution models, and fit the curves with \( f(R) = a + b R^2 + c R^3 + d R^4 \). All 4 models provides very similar values. The final value is

\[
\Delta E_{11,loop,fs}^{21,fs} (R) = 0.15102161 \\
- 0.000098409804 R^2 \\
+ 7.9038238 \times 10^{-8} R^3 \\
- 7.2004764 \times 10^{-7} R^4 \text{ meV}.
\]

The value calculated in Ref. [37] is 0.1509 meV and the one in Ref. [39] is 0.1510 meV in very good agreement with the present work. The method employed here provides in addition the proton size dependence for this
correction, which was not calculated before. For the fine structure, I obtain in the same way
\[ \Delta E_{2p_{1/2}^{-2p_{3/2}}}^{11,\text{loop}} (R) = 2.33197 \times 10^{-6} \]
\[ - 1.77101 \times 10^{-9} R^2 + 9.36429 \times 10^{-10} R^3 - 1.79951 \times 10^{-10} R^4 \text{ meV}. \] (61)

B. Other higher-order Uehling correction

Since we include the vacuum polarization in the Dirac equation potential, all energies calculated by perturbation using the numerical wavefunction contains the contribution of higher-order diagrams where the external legs, which represent the wavefunction, can be replaced by a wavefunction and a bound propagator with one, or several vacuum polarization insertion. For example the Källén and Sabry correction calculated in this way, contains correction of the type presented in Fig. 8. This correction is given by
\[ \Delta E_{2p_{1/2}^{-2p_{3/2}}}^{211,\text{fs}} (R) = 0.0021552 \]
\[ - 1.32976 \times 10^{-6} R^2 + 9.4577 \times 10^{-9} R^3 - 8.5185 \times 10^{-9} R^4 \text{ meV}, \] (62)
with a $10^{-7}$ meV accuracy. This correction is part of the three-loop corrections form Ref. [73, 74]. The diagrams in Fig. 8 correspond to diagrams (a) and (b) of Fig. 5 in Ref. [73] and (e) (upper left) and (f) in Fig. 2 of Ref. [75]. The sum of contributions of the diagram (a) and (b) is 0.00223, in good agreement with our all-order fully relativistic result. The three loop diagram Fig. 5 (c) Ref. [73] and Fig. 2 (g) Ref. [75] is included in the all-order contribution obtained by solving numerically the Dirac equation with the Uehling potential. For the

C. Wichmann and Kroll correction

We use the approximate potentials as presented in Refs. [68, 76] to evaluate the Wichmann and Kroll [77] $V_{13}$ correction to the Uehling potential. The corresponding diagram is shown on Fig. 4 (b). This contribution is given together with the light-by-light scattering diagrams of Fig. 9 in Refs. [73, 75, 78]. We find for a point nucleus, the exact value, and a size correction, given by
\[ \Delta E_{2p_{1/2}^{-2p_{3/2}}}^{13,\text{fs}} (R) = -0.0010170628 \]
\[ + 5.5414179 \times 10^{-8} R^2 - 5.1356872 \times 10^{-10} R^3 - 1.9364450 \times 10^{-11} R^4 \text{ meV}, \] (63)
to be compared to the value given in Ref. [75] (Table III) of $-0.001018(4)$ meV. In the lowest order approximation, the diagram on Fig. 9(a) provides an energy shift of $\Delta E_{13}/Z^2$ [75, 78]. For the fine structure, this correction is comparable to the contribution from Eq. (63):
\[ \Delta E_{2p_{1/2}^{-2p_{3/2}}}^{13,\text{fs}} (R) = -4.21088 \times 10^{-8} \]
\[ + 4.41081 \times 10^{-13} R^2 - 8.49036 \times 10^{-15} R^3 + 1.81474 \times 10^{-15} R^4 \text{ meV}. \] (65)
Highly accurate self-energy values for electronic atoms and point nucleus are known from Ref. [79]. The self-energy correction, represented in Fig. 10, is conveniently expressed by the slowly varying function \( F(Za) \) defined by

\[
\Delta E_{SE} = \frac{\alpha}{\pi} \frac{(Za)^4}{n^3} m c^2 F(Za),
\]

where \( m \) is the particle mass.

The recoil corrections to \( F(Za) \) are described in detail in [11]. The dependence in the reduced mass has to be included leading to the following expressions, specialized for the \( n = 2 \) shells:

\[
\Delta E_{\mu SE, 2s} = \frac{\alpha}{\pi} \frac{(Za)^4}{8} \left( \frac{\mu_e}{\mu}\right)^3 m \mu_e^2 \left(-\frac{4}{3} \ln k_0(2S) + \frac{10}{9}\right) + \frac{4}{3} \ln \left(\frac{m_e}{\alpha^2 \mu_e}\right) + \frac{139}{32} - 2 \ln 2 \right) \pi \alpha^2 + \frac{67}{30} + \frac{16}{3} \ln \left(\frac{m_e}{\alpha^2 \mu_e}\right) \frac{\alpha^2}{\left(\frac{m_e}{\alpha^2 \mu_e}\right)^{\frac{1}{2}}} - \left(\ln \left(\frac{m_e}{\alpha^2 \mu_e}\right)\right)^{\frac{3}{2}} \alpha^2 + \alpha^2 G_2(\alpha),
\]

\[
\Delta E_{\mu SE, 2p_{1/2}} = \frac{\alpha}{\pi} \frac{(Za)^4}{8} \left( \frac{\mu_e}{\mu}\right)^3 m \mu_e \left(-\frac{4}{3} \ln k_0(2P) - \frac{1}{6} \right) \left(\frac{m_e}{\mu}\right) + \frac{103}{180} \ln \left(\frac{m_e}{\alpha^2 \mu_e}\right) \frac{\alpha^2 + \alpha^2 G_{2p_{1/2}}(\alpha)}{\left(\frac{m_e}{\alpha^2 \mu_e}\right)^{\frac{1}{2}}}.
\]

and

\[
\Delta E_{\mu SE, 2p_{3/2}} = \frac{\alpha}{\pi} \frac{(Za)^4}{8} \left( \frac{\mu_e}{\mu}\right)^3 m \mu_e \left(-\frac{4}{3} \ln k_0(2P) + \frac{1}{12} \right) \left(\frac{m_e}{\mu}\right) + \frac{29}{90} \ln \left(\frac{m_e}{\alpha^2 \mu_e}\right) \frac{\alpha^2 + \alpha^2 G_{2p_{3/2}}(\alpha)}{\left(\frac{m_e}{\alpha^2 \mu_e}\right)^{\frac{1}{2}}}.
\]

The Bethe logarithms are given by \( \ln k_0(2S) = 2.811769893 \) and \( \ln k_0(2P) = -0.030016709 \) [80]. The the remaining factors are \( G_2(\alpha) = -31.85150(90), G_{2p_{1/2}}(\alpha) = -0.97350(20) \) and \( G_{2p_{3/2}}(\alpha) = -0.48650(20) \) [79, 81]. One then gets the exact muon self-energy for each state. For the 2s state, this gives 0.675150 meV instead of 0.675389 meV. For the 2p_{1/2} I get –0.00916882 meV and for 2p_{3/2}, 0.000893377 meV in place of 0.01420454 meV and –0.000332838 meV respectively, if one would use only the low order \( A_{40} \) term.

The finite size correction is given by perturbation theory [11] Eq. (54)

\[
E_{SE-NS}(R, Za) = \left(4 \ln 2 - \frac{23}{4}\right) \alpha(\pi \alpha) E_{NS}(R, Za),
\]

where ([11] Eq. (51))

\[
E_{NS}(R, Za) = \frac{2}{3} \left(\frac{\mu_e}{m}\right)^2 \left(\frac{Za}{\Lambda_C}\right)^2 \left(\frac{m_e}{a^3}\right),
\]

is the lowest-order finite nuclear size correction to the Coulomb energy. Here \( \Lambda_C = 1.8675942822 \) fm is the muon Compton wavelength. Equation (71) provides \( E_{NS}(R) = 5.19745R^2 \) for muonic hydrogen in agreement with Refs. [37, 39].

The self-energy correction to the Lamb shift with finite-size correction is then

\[
\Delta E_{SE, f} = \Delta E_{SE, f} - \Delta E_{SE, f} = -0.68431882 + 0.000824R^2 \text{ meV},
\]

and to the fine structure:

\[
\Delta E_{SE, fs} = \Delta E_{SE, fs} = 0.017562197 \text{ meV}.
\]

It should be noted that in Ref. [39], the \( R^2 \)-dependent part of the 2s self-energy is much larger than what is given in Eq. (72). This value was checked independently by using an all-order calculation with finite size, following the work of Mohr and Soff [82]. The results of this calculation agree reasonably well with Eq. (72) and is given by [83]

\[
E_{SE-NS}(Z = 1, R) = -0.68431882 + 0.0012176389R^2 - 0.0007582511R^3 + 0.00034744609R^4 - 0.000063788419R^5 \text{ meV}.
\]
2. Muon loop vacuum polarization

The vacuum polarization due to the creation of virtual muon pairs is represented by the same diagram 4 (a) and same equations (28) as vacuum polarization due to electron-positron pairs, replacing the electron Compton wavelength, and the muon Compton wavelength, which represent the scale of QED corrections for muons is of the order of the finite nuclear size (1.9 fm), one could expect a non-negligible finite size contribution. Using the wavefunction evaluated with the Uehling potential in the Dirac equation, I also obtain the value of the numerical coeﬃcient for the 2s level. This term is about 4 times larger than the numerical procedure described in Sec. II, replacing the electron Compton wavelength by the muon one in Eq. (28), I obtain

\[ E_{\mu VP}(ns) = -\frac{\alpha(aZ)^4}{\pi n^3} \left( -\frac{4}{15} + \frac{\pi a}{48} \right) \left( \frac{\mu_\mu}{m_\mu} \right)^3 m_\mu c^2, \]  

(75)

in which higher order terms in Zα have been neglected. For the 2s Lamb shift in muonic hydrogen it gives 0.01669 meV and is included in Refs. [37, 39] and [84] Eq. (2.29) for the first α correction. As it is a sizable contribution, and the muon Compton wavelength, which represent the scale of QED corrections for muons is of the order of the finite nuclear size (1.9 fm), one could expect a non-negligible finite size contribution. Using the numerical procedure described in Sec. II, replacing the electron Compton wavelength by the muon one in Eq. (28), I obtain

\[ \Delta E_{\mu VP}^{11s}(R) = 0.01671487464 \]

\[ -0.00005279721702 R^2 \]

\[ + 0.00001269866912 R^3 \]

\[ - 5.360546098 \times 10^{-4} R^4 \]

\[ + 0.00001717649157 R^2 \log(R) \]

\[ + 2.047113814 \times 10^{-5} R^4 \log(R) \text{ meV}, \]  

(76)

where the constant term is in excellent agreement with (75) and the R dependence explicit. From Ref. [11], Eq. (55), one obtains

\[ E_{\mu VP}(ns) = \frac{3}{4} a(Z\alpha) E_{\text{NS}}(R, \alpha) = 0.00020758 R^2 \text{ meV} \]  

(77)

for the 2s level. This term is about 4 times larger than the numerical coeﬃcient for R^2 in Eq. (76).

Using the wavefunction evaluated with the Uehling potential in the Dirac equation, I also obtain the value of the sum of diagrams with one muon vacuum polarization loop and any number of electron loops on each side, as in Fig. 7, with one loop being a muon loop:

\[ \Delta E_{\mu VP}^{11s}(R) = 0.00005348857 \]

\[ - 5.358667885 \times 10^{-7} R^2 \]

\[ + 6.495888541 \times 10^{-8} R^3 \]

\[ - 4.287455607 \times 10^{-8} R^4 \]

\[ + 2.822488184 \times 10^{-7} R^2 \log(R) \]

\[ + 1.739448734 \times 10^{-8} R^4 \log(R) \text{ meV}. \]  

(78)

This muonic vacuum polarization is a small contribution to the fine structure

\[ \Delta E_{\mu VP}^{11s}(R) = 1.67794 \times 10^{-7} \]

\[ - 2.10861 \times 10^{-10} R^2 \]

\[ + 8.51427 \times 10^{-11} R^3 \]

\[ - 1.38884 \times 10^{-11} R^4 \text{ meV}. \]  

VI. EVALUATION OF THE RECOIL CORRECTIONS

The relativistic treatment of recoil corrections is described in, e.g., [11], Eq. (10). The analytic solution of the Dirac equation for a point nucleus and a particle of mass m is given by

\[ E_D = mc^2 f(n, j) \]  

(80)

with

\[ f(n, j) = \frac{1}{\sqrt{1 + \frac{(Z\alpha)}{f(n, j) - 1/4}}} \]  

(81)

The recoil can then be included by evaluating [62, 85]

\[ E_M = M c^2 + \mu c^2 \left( f(n, j) - 1 \right) \]

\[ + \frac{1}{2} \mu c^2 \left( f(n, j) - 1 \right)^2 \frac{1}{2m} \]

\[ + \frac{1}{2} \mu c^2 \left( f(n, j) - 1 \right)^2 \frac{1}{2m} \]  

(82)

\[ + \frac{1}{2} \mu c^2 \left( f(n, j) - 1 \right)^2 \frac{1}{2m} \]  

(83)

where M = m + M_p. If one expands the previous equation in power of (Z\alpha)^4 one would find that the terms of order up to (Z\alpha)^4 are identical to what is given in Ref. [62]. We also compared the numerical results from our numerical approach for point nucleus, as described in Sec. I A to what can be obtained by using directly (80) and find excellent agreement. Below, we will make exclusive use of the direct numerical evaluation of the Dirac equation. The relativistic corrections to Eq. (83) associated with motion of the nucleus are called relativistic-recoil correction. The correction to order (Z\alpha)^2 and to all orders in m_\mu/M_p is given by [11, 41, 85, 86]

\[ E_{RR}(n, l) = \frac{\mu c^2}{m_\mu M_p} \left( Z\alpha \right)^5 \left( \delta_{l,0} \right) \frac{1}{3} \ln \left( \frac{1}{(Z\alpha)^2} \right) - \frac{8}{3} \ln k_0(l, n) \]

\[ - \frac{\delta_{l,0}}{9} - \frac{7}{3} \delta_{n,l} - \frac{2\delta_{l,0}}{M_p - m_\mu} \]

\[ \times \left[ M_p^2 \ln \left( \frac{m_\mu}{\mu_\mu} \right) - m_\mu^2 \ln \left( \frac{M_p}{\mu_\mu} \right) \right] \]  

(84)

where

\[ a_{n,l} = \left\{ \begin{array}{ll}
- \frac{1}{n} + \sum_{i=1}^{n} \frac{1}{i} & \text{if } l = 0 \\
+ \frac{1}{l(l+1)(2l+1)} & \text{if } l \neq 0
\end{array} \right. \]  

(85)
This correction corresponds to the diagrams in Fig. 11. The next order of the relativistic recoil corrections is given for s states by

\[ E_{RR}^s(ns) = \frac{m_\mu (Za)^s}{Mp} \frac{m_\mu c^2}{n^3} \left\{ 4 \ln 2 - \frac{7}{2} - \frac{11}{60\pi} \ln \left( \frac{1}{(Za)^2} \right) \right\} \]  

and for \( l \geq 1 \) states by

\[ E_{RR}^s(ml) = \frac{m_\mu (Za)^s}{Mp} \frac{m_\mu c^2}{n^3} \left\{ \left[ 3 - \frac{l(1 + l)}{n^2} \right] \times \left( \frac{2}{(4l^2 - 1)(2l + 3)} \right) \right\} \]  

Using Eqs. (82) to (87), I obtain

\[ \Delta E_{Rec}^{2s1/2-2p1/2} = 0 + 0.0574706 - 0.0449705 = 0.0125001 \text{meV}, \]  

and to the fine structure:

\[ \Delta E_{Rec}^{2p1/2-2p3/2} = 0.0000051 - 0.0862059 + 0 = -0.0862008 \text{meV}. \]  

This is in excellent agreement with the results from Ref. [70].

**VII. EVALUATION OF SOME ALL-ORDER HYPERFINE STRUCTURE CORRECTIONS**

The expression of the hyperfine magnetic dipole operator can be written as

\[ H_{\text{hf}} = -e c \alpha \cdot A(r) = -e c \alpha \cdot A(r), \]  

with

\[ A(r) = \frac{\mu_0 \mu}{4\pi} \frac{\mathbf{r}}{r^3}, \]  

where \( \mu \) is the nuclear magnetic moment and we have assumed a magnetic moment distribution of a point particle for the nucleus. It is convenient to express \( H_{\text{hf}} \) using vector spherical harmonics. On obtains [87–90]

\[ H_{\text{hf}} = M^1 \cdot T^1, \]  

where

\[ T^1(r) = -ie \sqrt{\frac{8\pi}{3}} \frac{\alpha \cdot Y_1^0(\hat{r})}{r}, \]  

and \( M^1 \) representing the magnetic moment operator from the nucleus. The operator \( T^1 \) acts only on the bound particle coordinates. The vector spherical harmonic \( Y_1^0(\hat{r}) \) is an eigenfunction of \( J^2 \) and \( J_z \), defined as [88, 90–93]

\[ Y_1^0(\hat{r}) = Y_{1q}(\hat{r}) = \sum_o C(1, 1; q - \sigma, \sigma, q) Y_{1,q - \sigma}(\hat{r}) \xi_\sigma \]  

where \( C(j_1, j_2, j; m_1, m_2, m) \) is a Clebsh-Gordan coefficient, \( Y_{1q} \) are scalar spherical harmonic and \( \xi_\sigma \) are eigenvectors of \( s^2 \) and \( s_z \), the spin 1 matrices [88, 90–93]. The reduction to radial and angular integrals is presented in various works [88–90]. In heavy atoms, the hyperfine structure correction due to the magnetic moment contribution is usually calculated for a finite charge distribution, but a point magnetic dipole moment (see, e.g., [88, 89]). When matrix elements non-diagonal in \( J \) are needed, one can use [94] for a one-particle atom

\[ \Delta E_{\text{HFS}}^\text{M1} = A \frac{g_\alpha}{2Mp} \int_0^\infty dr P_1(r)Q_2(r) + P_2(r)Q_1(r) \frac{r^2}{r^2}, \]  

where \( g = \mu_\mu/2 = 2.792847356 \) for the proton, is the anomalous magnetic moment, \( A \) is an angular coefficient

\[ A = (-1)^{l_1 + F} \left\{ \begin{array}{c} I \ j_1 \ F \\ j_2 \ k \ \end{array} \right\} \left( \begin{array}{c} I \ j_2 \ k \\ -I \ -0 \ 1 \end{array} \right) \times (-1)^{l_1 - j_2} \sqrt{(2j_1 + 1)(2j_2 + 1)} \left( \begin{array}{c} j_1 \ 1 \ 0 \\ -j_2 \ -0 \ 2 \end{array} \right) \pi(l_1, k, l_2), \]  

where \( \pi(l_1, k, l_2) = 0 \) if \( l_1 + l_2 + 1 \) is odd and 1 otherwise. The \( j_i \) are the total angular momentum of the \( i \) state for the bound particle, \( l_i \) are orbital angular momentum, \( I \) is the nuclear spin, \( k \) the multipole order (\( k = 1 \) for the magnetic dipole contribution described in Eq. (95)) and \( F \) the total angular momentum of the atom. The difference between \( \Delta E_{\text{HFS}} \) values calculated with a finite or point nuclear charge distribution is called the Breit-Rosenthal correction [95].

To consider a finite magnetic moment distribution, one uses the Bohr-Weisskopf correction [96]. The correction can be written [97]

\[ \Delta E_{\text{BW}} = -A \frac{c_\alpha}{2Mp} \int_0^\infty dr d^2\rho(\mathbf{r}) \left( \begin{array}{c} P_1(r)Q_2(r) + P_2(r)Q_1(r) \\ \end{array} \right) \frac{r^2}{r^2}, \]  

FIG. 11. Feynman diagrams corresponding to the Relativistic recoil correction (84). The heavy double line represents the proton wave function or propagator. The other symbols are explained in Fig. 4.
where the magnetic moment density $\mu(r_n)$ is normalized as
\[ \int_0^{\infty} dr_n r_n^2 \mu(r_n) = 1. \]  
(98)

Borie and Rinker [98], write the total diagonal hyperfine energy correction for a muonic atom as
\[ \Delta E_{i,j} = \frac{4\pi \kappa}{2M_p} \left( F(F + 1) - I(I + 1) - j(j + 1) \right) \frac{g\alpha}{\kappa^2 - \frac{1}{4}} \times \int_0^{\infty} dr \frac{P_1(r) Q_2(r)}{r^2} \int_0^{\infty} dr_n r_n^2 \mu_{BR}(r_n). \]  
(99)

where the normalization is different:
\[ \int_0^{\infty} \int d^3 r_n \mu_{BR}(r_n) = 4\pi \int_0^{\infty} dr_n r_n^2 \mu_{BR}(r_n) = 1. \]  
(100)

This means that $\mu_{BR}(r) = \mu(r)/(4\pi)$. Evaluation of the Wigner 3J and 6J symbols in (96) give the same angular factor than in Eq. (95).

The equivalence of the two formalism can be easily checked: starting from (99) and dropping the angular factors, we get, doing an integration by part
\[
\int_0^{\infty} dr \frac{P_1(r) Q_2(r)}{r^2} \int_0^{\infty} dr_n r_n^2 \mu(r_n)
= \left[ \int_0^{\infty} dr_n r_n^2 \mu(r_n) \int_0^{\infty} dt \frac{P_1(t) Q_2(t)}{t^2} \right]_0^\infty
- \int_0^{\infty} dr_n r_n^2 \mu(r_n) \int_0^{\infty} dr \frac{P_1(r) Q_2(r)}{r^2}
= \left[ \int_0^{\infty} dr \frac{P_1(r) Q_2(r)}{r^2} \right]_0^{\infty}
- \int_0^{\infty} dr_n r_n^2 \mu(r_n) \int_0^{\infty} dr \frac{P_1(r) Q_2(r)}{r^2}, \]  
(101)

where we have used (98). We thus find that the formula in Borie and Rinker represents the full hyperfine structure correction, including the Bohr-Weisskopf part.

In 1956, Zemach [99] calculated the fine structure energy of hydrogen, including recoil effects. He showed that in first order in the finite size, the HFS depends on the charge and magnetic distribution moments only through the Zemach’s form factor defined in Eq. (15). The proton is assumed to be at the origin of coordinates. Its charge and magnetic moment distribution are given in terms of charge distribution $\rho(r)$ and magnetic moment distributions $\mu(r)$. Zemach calculate the correction in first order to the hyperfine energy of s-states of hydrogen due to the electric charge distribution. The HFS energy is written as
\[ \Delta E_{\text{HFS}}^Z = -\frac{2}{3} \left\langle S_p \cdot S_e \right\rangle \int |\phi(r)|^2 \mu(r) dr \]  
(102)

$\phi$ the non-relativistic electron wavefunction and $S_e$ are the spin operators of the electron and proton. If the magnetic moment distribution is taken to be the one of a point charge, $\mu(r) = \delta(r)$, the integral reduces to $|\phi(0)|^2$.

The first order correction to the wavefunction due to the nucleus finite charge distribution is given by
\[ \phi(r) = \phi_0(r) \left( 1 - a \mu_p \int \rho(u) |u - r| du \right), \]  
(103)

where $\phi_0(r)$ is the unperturbed Coulomb wavefunction. Replacing into Eq. (102) and keeping only first order terms, we get (Eq. 2.8 of Ref. [99] corrected for a misprint):
\[ \Delta E_{\text{HFS}}^Z = -\frac{2}{3} \left\langle S_p \cdot S_e \right\rangle |\phi_0(0)|^2 \int \left( 1 - 2a \mu_p \int \rho(u) |u - r| \mu(r) du \right) dr, \]  
(104)

where $E_F$ is the well known HFS Fermi energy. Transforming Eq. (104) using $r \rightarrow r + u$, etc. Zemach obtains
\[ \Delta E_{\text{HFS}}^Z = E_F \left( 1 - 2a \mu_p \langle uz \rangle, \right), \]  
(105)

with $\langle uz \rangle$ given in Eq. (16). The 2s state Fermi energy is given by
\[ E_{F}^{2s} = \frac{(Z0)^4}{3} \frac{\mu^2}{m_p m_n}. \]  
(106)

### A. Hyperfine structure of the 2s level

In order to check the dependence of the hyperfine structure on the Zemach radius and on the proton finite size, I have performed a series of calculations for a dipolar distribution for both the charge and magnetic moment distribution. We can then study the dependence of the HFS beyond the first order corresponding to the Zemach correction. I calculated the hyperfine energy splitting $\Delta E_{\text{HFS}}(R, Z) = E_{\text{HFS}}(R) + E_{\text{HFS}}^Z(R, R_M)$ numerically. I also evaluate with and without self-consistent inclusion of the Uehling potential in the calculation, to obtain all-order Uehling contribution to the HFS energy. We calculated the correction $\Delta E_{\text{HFS}}(R, Z)$ for several value of $R_Z$ between 0.8 fm and 1.15 fm, and proton sizes ranging from 0.3 fm to 1.2 fm, by steps of 0.05 fm, which represents 285 values. The results show that the correction to the HFS energy due to charge and magnetic moment distribution is not quite independent of $R$ as one would expect from Eq. (105), in which the finite size contribution depends only on $R_Z$. We fitted the hyperfine structure splitting of the 2s level, $E_{\text{HFS}}^{2s}(R, Z)$ by a...
function of $R$ and $R_Z$, which gives:

$$E_{\text{HFS}}^{2s}(R_Z,R) = 22.807995 \left(-0.0022324349R^2 + 0.00072910794R^3 - 0.00065912957R^4 - 0.16034434R_Z - 0.00057179529RR_Z - 0.00069518048R^2R_Z - 0.00018463878R^3R_Z + 0.0010566454R_Z^2 + 0.00096830453RR_Z^2 - 0.00048210961R_Z^3 - 0.00041573690RR_Z^3 + 0.00018238754R_Z^4 + 0.00018238754R_Z^4\right) \text{meV}. \quad (107)$$

The constant term should be close to the sum of the Fermi energy 22.80541 meV and of the Breit term [100], the HFS correction calculated with a point-nucleus Dirac wavefunction for which I find 22.807995 meV. When setting the speed of light to infinity in the program I recover exactly the Fermi energy. The Breit contribution is thus 0.002595 meV, to be compared to 0.0026 meV in Ref. [40] (Table II, line 3) and 0.00258 meV in Ref. [70]. Martynenko [40] evaluates this correction, which he names “Proton structure corrections of order $a^5$ and $a^6$”, to be $-0.1535$ meV, following [35]. He finds the coefficient for the Zemach’s radius to be $-0.16018$ meV$m^{-1}$, in very good agreement with the present all-order calculation $-0.16034$ meV$m^{-1}$. Borie’s value [70] $-0.16037$ meV$m^{-1}$ is even closer. The difference between Borie’s value and Eq. (107) is represented in Fig. 12 as a function of the charge and Zemach radii. The maximum difference is around 1 $\mu$eV.

In Ref. [35], the charge and magnetic moment distributions are written down in the dipole form, which corresponds to (13),

$$G_E(q^2) = G_M(q^2) = \frac{\Lambda^4}{(\Lambda^2 + q^2)^2}. \quad (108)$$

with $\Lambda = 848.5$MeV. This leads to $R = 0.806$ fm as in Ref. [2] and $R_Z = 1.017$ fm using this definition for the form factor in Eq. (17). Moreover there are recoil corrections included. Pachucki [35] finds that the pure Zemach contribution (in the limit $m_p \to \infty$) is $-0.183$ meV. In Ref. [101], the Zemach corrections are given as $\delta(\text{Zemach}) \times E_F = -71.80 \times 10^{-4}E_F$, for $R_Z = 1.022$ fm. This leads to a coefficient $-0.1602$ meVfm$^{-1}$, in excellent agreement with our value $-0.16036$ meVfm$^{-1}$.

The effect of the vacuum polarization on the 2s hyperfine structure energy shift as a function of the Zemach and charge radius have been calculated for the same set of values as the main contribution. The data can be described as a function of $R_Z$ and $R$ as

$$E_{\text{HFS}}^{2s, VP}(R_Z,R) = 0.074369030 + 0.000074236132R^2 + 0.00013277334R^3 - 8.0987285 \times 10^{-6}R^4 - 0.0017880269R_Z - 0.00017204505R_ZR^2 - 0.00037499458R_Z^2 - 0.000070355379R_Z^3 - 0.00022093411R_Z^2 + 0.00035038656R_Z^3 + 0.0020554316RR_Z^2 + 0.0002510064RR_Z^3 - 0.00017204505R_Z^3 - 0.00061266973R_Z^4 \text{meV}. \quad (109)$$

It corresponds to the diagrams presented in Fig. 13. The size-independent term 0.07437 meV corresponds to the sum of the two contributions represented by the two top diagrams in Fig. 13 and is given as $\Delta E_{\text{HFS}}^{\text{loop after loop VP}} = 0.0746$ meV in Ref. [40]. The term $\Delta E_{\text{HFS}}^{\text{odd VP}} = 0.0481$ meV corresponds to a vacuum polarization loop in the HFS potential [35, 40, 98], which is not evaluated here. Corrections present in Ref. [70] not included in Eqs. (107) and (109) gives an extra contribution of

$$E_{\text{HFS}}^{2s, HO} = 0.10287 \text{meV}. \quad (110)$$
Combining Eqs. (107), (109) and (110), I get

\[ E_{\text{HFS}}^{2s}(R_Z, R) = 22.985234 - 0.0021581988R^2 \\
+ 0.00086188128R^3 \\
- 0.00074011685R^4 \\
- 0.16213237R_Z \\
- 0.00074384033RR_Z \\
- 0.0010701751R_Z \\
- 0.00025499415R^3R_Z \\
+ 0.00083571133R^2R_Z \\
+ 0.16213237 \\
- 0.00074384033RR_Z \\
- 0.0010701751R_Z \\
- 0.00025499415R^3R_Z \\
+ 0.00083571133R^2R_Z \\
+ 0.00058437789R^2R_Z \\
- 0.000074011685R^4 \\
- 0.00008618128R^3 \\
+ 0.0013186911R^2R_Z \\
+ 0.00058774125R^3R_Z \\
- 0.000074011685R^4 \\
- 0.00008618128R^3 \\
+ 0.0013186911R^2R_Z \\
+ 0.00058774125R^3R_Z \\
- 0.000074011685R^4 \\
- 0.00008618128R^3 \\
+ 0.0013186911R^2R_Z \\
+ 0.00058774125R^3R_Z \\
- 0.000074011685R^4 \\
- 0.00008618128R^3 \\
+ 0.0013186911R^2R_Z \\
+ 0.00058774125R^3R_Z \\
- 0.000074011685R^4 \\
- 0.00008618128R^3 \\
+ 0.0013186911R^2R_Z \\
+ 0.00058774125R^3R_Z \text{meV.} \tag{111} \]

In Ref. [40], the equivalent expression is

\[ E_{\text{HFS}}^{2s, \text{Mart.}}(R_Z) = 22.9857 - 0.16018R_Z \text{ meV,} \tag{112} \]

while it is

\[ E_{\text{HFS}}^{2s, \text{Borie}}(R_Z) = 22.9857 - 0.16018R_Z \text{ meV,} \tag{113} \]

in Ref. [70]. Using a Zemach’s radius of 0.9477 fm in Eq. (112), needed to reproduce entry 11 in Table II of Ref. [40], one obtains 22.8148 meV as expected. In Eq. (113), it gives 22.8107 meV. Using the same Zemach radius and Eq. (111) I obtain 22.8104 meV with the muonic hydrogen proton radius value and 22.8103 meV with the CODATA one, in excellent agreement with Borie’s value. All three values are in agreement with the result 22.8146(49) meV in Ref. [19]. In a recent work, however, the use of form factors in the Breit equations leads to smaller finite size corrections, leading to 22.8560 meV [102]. A comparison between some of these results is presented in Table I.

VIII. EVALUATION OF MUONIC HYDROGEN \( n = 2 \) TRANSITIONS

A. Lamb shift and fine structure

The results presented in this work for the Lamb shift (Eqs. (45), (54), (57), (60), (62), (64), (72), (76), (78)) can be summarized in the following proton-size dependent equation:

\[ \Delta E_{\text{Tot, fs}}^{2p_{1/2} \rightarrow 2p_{3/2}}(R) = 206.0209137 - 5.226135625R^2 \\
+ 0.03432100160R^3 \\
- 0.0000545464275R^4 \\
- 0.000857557042R^5 \\
+ 0.0002962967640R^6 \log(R) \\
- 0.00004751147090R^6 \log(R) \text{ meV.} \tag{114} \]

In the same way, Eqs. (46), (55), (58), (61), (63), (65), (73), (79), and (89) lead to the fine structure interval (which include the recoil corrections (89), included in Table II for the 2s Lamb shift)

\[ \Delta E_{\text{Tot, fs}}^{2s}(R) = 8.352051651 \\
- 0.00005203798087R^2 \\
+ 1.215060759 \times 10^{-7}R^3 \\
- 1.544056441 \times 10^{-9}R^4 \text{ meV.} \tag{115} \]

Martynenko [105] finds \( E_{\text{Tot, fs}}^{2p_{1/2} \rightarrow 2p_{3/2}} = 8.352082 \text{ meV} \) for the fine structure.

A number of terms not included in Eqs. (114) are presented in Table II together with the relevant references. Combining Eq. (114) with the sum of the contributions
TABLE I. Comparison of contributions to the 2s hyperfine structure from Refs. [40, 70] and the present work (meV) for $R_z = 1.0668 \text{ fm}$ [2] as used in Ref. [40]. Note that in this reference, the proton structure correction of order $\alpha^5$ (item # 6) may combine the Zemach correction and the recoil correction (# 24). VP: Vacuum Polarization.

An extra recoil contribution is given in Ref. [72] for the fine structure, corresponding to entry #9 in Table II for the Lamb shift, \[ \Delta E_{\text{VPPrec}}^{\text{Tot}}(R) = -0.00006359 \text{ meV}. \] (119)

This term correspond to corrections beyond the full Dirac term. This lead to the final result \[ \Delta E_{2s_{1/2}-2p_{1/2}}^{\text{Tot}}(R) = 8.351988061 - 0.00005203798087 R^2 + 1.215060759 \times 10^{-7} R^3 - 1.544056441 \times 10^{-9} R^4 \text{ meV}. \] (120)

contained in Table II, I obtain the final $2s - 2p_{1/2}$ energy:

\[
\Delta E_{2s_{1/2}-2p_{1/2}}^{\text{Tot,fs}}(R) = 206.0579(60) - 5.22713R^2 + 0.0365(18)R^3 \text{ meV},
\] (117)

This can be compared with the result from E. Borie [70]

\[
\Delta E_{2s_{1/2}-2p_{1/2}}^{\text{Borie,fs}}(R) = 206.0579(60) - 5.22713R^2 + 0.0365(18)R^3 \text{ meV},
\] (117)

and Carroll et al. [106]

\[
\Delta E_{2s_{1/2}-2p_{1/2}}^{\text{Carlson,fs}}(R) = 206.0604 - 5.2794R^2 + 0.0546R^3 \text{ meV}.
\] (118)
TABLE II. Contributions to the Lamb shift not included in Eq. (114) (meV). The uncertainty on the proton polarization value used in Ref. [12] has been increased by a factor of 10, according to the discussion in Ref. [26].

| #  | Contribution                                                                 | Reference | Value   | Unc.    |

B. Transitions between hyperfine sublevels

The energies of the two transitions observed experimentally in muonic hydrogen are given by

\[
E_{2p_{1/2}}^{F=2} - E_{2p_{1/2}}^{F=0} = \Delta E_{2s_{1/2}-2p_{1/2}} + \Delta E_{2p_{1/2}-2p_{3/2}} + \frac{3}{8}E_{\text{HFS}}^{2p_{3/2}} - \frac{1}{4}E_{\text{HFS}}^{2p_{1/2}},
\]

(121)

and

\[
E_{2p_{3/2}}^{F=1} - E_{2p_{3/2}}^{F=0} = \Delta E_{2s_{1/2}-2p_{3/2}} + \Delta E_{2p_{1/2}-2p_{3/2}} - \frac{5}{8}E_{\text{HFS}}^{2p_{3/2}} + \frac{3}{4}E_{\text{HFS}}^{2p_{1/2}} + \delta E_{\text{HFS}},
\]

(122)

Here we use the results from [105] for the \(2p\) states:

\[
E_{\text{HFS}}^{2p_{1/2}} = 7.964364 \text{ meV}
\]
\[
E_{\text{HFS}}^{2p_{3/2}} = 3.392588 \text{ meV}
\]
\[
\delta E_{\text{HFS}} = 0.14456 \text{ meV}.
\]

Using the results presented above I get

\[
E_{2p_{1/2}}^{F=2} (R_Z, R) - E_{2p_{1/2}}^{F=1} (R_Z, R) = 209.92441
\]

- \(5.2261075R^2\)
- \(0.034379506R^3\)
+ \(0.00043287446R^4\)
- \(0.000063788419R^5\)
+ \(0.040533092R_Z\)
+ \(0.001859608RR_Z\)
+ \(0.00026754376R^2R_Z\)
+ \(0.000063748539RR_Z\)
- \(0.00020892783R^2R_Z\)
- \(0.00032967277RR_Z\)
- \(0.00014609447R^2R_Z\)
+ \(0.00005777598R^3\)
+ \(0.00014693531R^3\)
- \(0.000030280142R^4\)
+ \(0.00029629678R^2\log(R)\)
- \(0.000047511471R^4\log(R)\)

This can be compared with the result from

\[
17
\]
TABLE III

| Year | proton RMS charge radius (fm) |
|------|-------------------------------|
| 1960 | 0.79                          |
| 1970 | 0.81                          |
| 1980 | 0.83                          |
| 1990 | 0.85                          |
| 2000 | 0.87                          |
| 2010 | 0.89                          |
| 2020 | 0.91                          |

Using Eq. (124), a Zemach radius of 1.0668 fm from Ref. [40] and the transition energy from Ref. [12], I obtain a charge radius for the proton of 0.8775(51) fm in the 2010 CODATA fundamental constant adjustment. This is 7.1σ (using the combined σ) from the 2010 CODATA value. A summary of proton size determinations is presented in Table III and Fig. 14.

IX. CONCLUSION

In the present work, I have evaluated finite-size dependent contributions to the n = 2 Lamb shift in muonic hydrogen, to the fine structure and to the 2s hyperfine splitting. The calculations were performed numerically, to all order in the finite size correction, in the framework of the Dirac equation. High-order size contributions to the Uehling potential and to higher-order QED corrections have been evaluated. The full dependence of the 2s hyperfine splitting on the proton charge distribution and Zemach radius has been evaluated as well.

The discrepancy between the proton size deduced from muonic hydrogen and the one coming from CODATA is slightly enlarged when taking into account all the newly calculated effects. It is changed from 6.9σ to 7.1σ.

ACKNOWLEDGMENTS

The author wishes to thank Randolf Pohl, Eric-Olivier Le Bigot, François Nez, François Biraben and several other members of the CREMA collaboration for numerous and enlightening discussions and Jean-Paul Desciaux for help in implementing some new corrections in the MCD code. Special thanks go to Peter Mohr for several invitation to NIST where part of this work was performed, many discussions and for critical reading of part of the manuscript. I also thank Michael Distler for providing me with the charge density deduced from the MAMI experiment and Krzysztof Pachuki for his suggestion to introduce the logarithmic contribution to the fits. I thank also Franz Kottmann and Aldo Antognini for a critical and detailed reading of the manuscript.

The Feynman diagrams presented in the figures are realized with JAXODRAW [128]. This research was partly supported by the Helmholtz Alliance HA216/EMML Laboratoire Kastler Brossel is “Unité Mixte de Recherche n° 8552” of Ecole Normale Supérieure, CNRS and Université Pierre et Marie Curie.

Appendix A: Coefficients for the numerical evaluation of the Källén and Sabry potential for a point nucleus

The functions defined in Eq. (35) are given here. We find, for \( x \leq 3 \), the functions valid for a point nucleus:

\[
g_0(r) = 0.00013575124407339550307 r^8 - 0.0001263396034194731891 r^7 + 0.002375419311915541914 r^6 - 0.005246027187885263513 r^5 + 0.169255892525411005 r^4 + 0.25201860708873574898 r^3 + 0.951099841629190098905 r^2 - 2.0864972181198001792 r + 1.6459704071917522632,
\]

and

\[
g_1(r) = -0.000078684672329473358699 r^8 - 0.001229314186424835524 r^7 - 0.097906849416525020713 r^6 - 0.41666290189975666225 r^5 + 0.13769050748433509769 r,
\]

For \( x > 3 \), we fitted the coefficients in Eq. (40) to the numerical values. We obtain

\[
a = 3.493292650910
\]
\[
b = -10.059551479890
\]
\[
c = 5.549363222582
\]
\[
d = 5.3327556570422
\]
\[
e = -9.0762837836987
\]
\[
f = 5.1094977559523.
\]

Using these functions we reach an agreement to 9 decimal place with both the result of the numerical evaluation and the expansion from [68].
Appendix B: Coefficients for the numerical evaluation of the Källén and Sabry potential for a finite nucleus.

The coefficients for the functions defined in Eq. (39) that we obtained are listed below:

\[ h_0(r) = -0.00001608988362060r^6 
+ 0.000015791745043r^8 
- 0.00036443366062r^7 
+ 0.0008743378646r^9 
- 0.038046259798r^5 
+ 0.063004651772r^4 
- 0.36332915853r^3 
+ 1.04324860906r^2 
- 2.39716878893r + 2.005566300 \]  

\[ g_1(r) = 0.7511983817345282548 
+ 0.1388876396658555408r^2 
+ 0.020975409736870016795r^4 
+ 0.00017561631242035479319r^6 
+ 9.057708511987165794 \times 10^{-6}r^8 \]  

and

\[ g_2(r) = -0.44444444460943167625r^4 
- 0.003485099639125316319r^6 
- 1.417352139205566219 \times 10^{-6}r^8 . \]
