Abstract. We explore the electromagnetic gauge invariance of the hadron tensor of the Drell-Yan process with one transversely polarized hadron. The special role is played by the contour gauge for gluon fields. The prescription for the gluonic pole in the twist 3 correlator is related to causality property and compared with the prescriptions for exclusive hard processes. As a result we get the extra contributions, which naively do not have an imaginary phase. The single spin asymmetry for the Drell-Yan process is accordingly enhanced by the factor of two.

1. Introduction
The problem of the electromagnetic gauge invariance in the deeply virtual Compton scattering (DVCS) and similar exclusive processes has intensively been discussed during last few years, see for example [1, 2, 3, 4, 5, 6]. This development explored the similarity with the earlier studied inclusive spin-dependent processes [7], and the transverse component of momentum transfer in DVCS corresponds to the transverse spin in DIS. Here we combine the different approaches to apply them in the relevant case of the Drell-Yan (DY) process where one of hadrons is the transversely polarized nucleon. The source of the imaginary part, when one calculates the single spin asymmetry associated with the DY process, is the quark propagator in the diagrams with quark-gluon (twist three) correlators. This leads [8, 9] to the gluonic pole contribution to SSA. The reason is that these boundary conditions provide the purely real quark-gluon function $B^V(x_1, x_2)$ which parameterizes $\langle \bar{\psi} \gamma^+ A_\mu^V \psi \rangle$ matrix element. By this fact the diagrams with two-particle correlators do not contribute to the imaginary part of the hadron tensor related to the SSA [10]. In our paper, we perform a thorough analysis of the transverse polarized DY hadron tensor in the light of the QED gauge invariance, the causality and gluonic pole contributions. We show that, in contrast to the naive assumption, our new-found additional contribution is directly related to the certain complex prescription in the gluonic pole $1/(x_1 - x_2)$ of the quark-gluon function $B^V(x_1, x_2)$ (cf. [11] and see e.g.[12] and Refs. therein). Finally, the account for this extra contributions corrects the SSA formula for the transverse polarized Drell-Yan process by the factor of 2. Note that our analysis is also important in view of the recent investigation of...
DY process within both the collinear and the transverse-momentum factorization schemes with hadrons replaced by on-shell parton states [13].

2. Causality and contour gauge for the gluonic pole

We study the contribution to the hadron tensor which is related to the single spin (left-right) asymmetry measured in the Drell-Yan process with the transversely polarized nucleon. The DY process with the transversely polarized target manifests [8] the gluonic pole contributions. Since we perform our calculations within a collinear factorization, it is convenient (see, e.g., [15]) to fix the dominant light-cone directions for the DY process shown at Fig. 1 with the standard hadron tensor generated by the diagram depicted on Fig. 1(a):

\[ W^{(1)}_{\mu\nu} = \int d^4k_1 d^4k_2 \delta^{(4)}(k_1 + k_2 - q) \int d^4\ell \Phi^{(A)}_\alpha[\gamma^+] \Phi[\gamma^-] \text{tr} \left[ \gamma_\mu \gamma^- \gamma_\nu \gamma^+ \frac{\ell^+ \gamma^- - k^- \gamma^+}{-2\ell^+ k^- + i\epsilon} \right], \]  

(1)

where \( \Phi^{(A)}_\alpha[\gamma^+] \) and \( \Phi[\gamma^-] \) defined as in [16]. Analyzing the \( \gamma \)-structure of (1), we may conclude that the first term in the quark propagator singles out the combination: \( \gamma^+ \gamma\alpha \gamma^- \) with \( \alpha = T \) which will lead to the matrix element of the twist three operator, \( \langle \bar{\psi} \gamma^+ A^\mu \psi \rangle \) with the transverse gluon field. After factorization, this matrix element will be parametrized via the function \( B^V(x_1, x_2) \). The second term in the numerator of the quark propagator separates out the combination \( \gamma^+ \gamma\alpha \gamma^+ \) with \( \alpha = - \). Therefore, this term will give \( \langle \bar{\psi} \gamma^+ A^\mu \gamma^- \psi \rangle \) which, as we will see now, will be exponentiated in the Wilson line \([ -\infty, 0^- ]\) (see details of this in [16, 17]). To eliminate the unphysical gluons from our consideration and use the factorization scheme [7], we may choose a contour gauge [18]

\[ [-\infty, 0^-] = 1 \]  

(2)

which actually implies also the axial gauge \( A^+ = 0 \) used in [7]. Imposing this gauge one arrives [18] at the following representation of the gluon field in terms of the strength tensor:

\[ A^\mu(z) = \int_{-\infty}^{\infty} d\omega^+ (z^- - \omega^-) G^{+\mu}(\omega^-) + A^\mu(-\infty) \]  

(3)

Moreover, if we choose instead an alternative representation for the gluon in the form with \( A^\mu(\infty) \), keeping the causal prescription \( +i\epsilon \) in (1), the cost of this will be the breaking of the electromagnetic gauge invariance for the DY tensor. Consider now the term with \( \ell^+ \gamma^- \) in (1) which gives us finally the matrix element of the twist 3 operator with the transverse gluon field. The parametrization of the relevant matrix elements is

\[ \langle p_1, S^T | \bar{\psi}(\lambda_1 \tilde{n}) \gamma_\beta g A^T(\lambda_2 \tilde{n}) \gamma_\alpha(\tilde{n}) \psi(0) | p_2 \rangle \frac{x_2^{-1}}{x_2} \]  

(4)

Using the representation (3), this function can be expressed as

\[ B^V(x_1, x_2) = \frac{T(x_1, x_2)}{x_1 - x_2 + i\epsilon} + \delta(x_1 - x_2)B^V_{A(\infty)}(x_1), \]  

(5)

where the real regular function \( T(x_1, x_2) \) ( \( T(x, x) \neq 0 \) ) parametrizes the vector matrix element of the operator involving the tensor \( G^\mu_\nu \) (cf. [19]):

\[ \langle p_1, S^T | \bar{\psi}(\lambda_1 \tilde{n}) \gamma_\beta g A^T(\lambda_2 \tilde{n}) \gamma_\alpha(\tilde{n}) \psi(0) | p_2 \rangle \frac{x_2^{-1}}{x_2} \]  

(6)
Fig. 1(b). The corresponding hadron tensor takes the form: if the gluonic pole is present. We now focus on the contribution from the diagram depicted on

We are now in position to check the QED gauge invariance by contraction with the photon

Owing to the time-reversal invariance, the function $B^V_{A(-\infty)}(x_1)$,

\[ i\bar{\epsilon}_\alpha S^T p_1 \delta(x_1 - x_2) B^V_{A(\pm\infty)}(x_1) = \langle p_1, S^T | \bar{\psi}(\lambda_1 \bar{n}) \gamma_\beta g A^T_{\alpha}(\pm\infty) \psi(0) | S^T, p_1 \rangle, \]

can be chosen as $B^V_{A(-\infty)}(x) = 0$. Indeed, the function $B^V(x_1, x_2)$ is an antisymmetric function of its arguments [7], while the anti-symmetrization of the additional term with $B^V_{A(-\infty)}(x_1)$ gives zero. If the only source of the imaginary part of the hadron tensor is the quark propagator, one may realize this property by assumption: $B^V(x_1, x_2) = T(x_1, x_2) \mathcal{P}/(x_1 - x_2)$ corresponding to asymmetric boundary condition for gluons [9]: $B^V_{A(\infty)}(x) = -B^V_{A(-\infty)}(x)$. Here we suggest another way of reasoning. The causal prescription for the quark propagator, generating its imaginary part, simultaneously leads to the imaginary part of the gluonic pole. We emphasize that this does not mean the appearance of imaginary part of matrix element but rather the prescription of its convolution with hard part (see e.g. [20]). Note that the fixed complex prescription $+i\epsilon$ in the gluonic pole of $B^V(x_1, x_2)$ (see, (5)) is one of our main results and is very crucial for an extra contribution to hadron tensor we are now ready to explore. Indeed, the gauge condition must be the same for all the diagrams, and it leads to the appearance of imaginary phase of the diagram (see, Fig. 1(b)) which naively does not have it. Let us confirm this by explicit calculation.

3. Hadron tensor and gauge invariance

We now return to the hadron tensor and calculate the part involving $\ell^+\gamma^-$, obtaining the following expression for the standard hadron tensor (see, the diagram on Fig. 1(a)):

\[ \mathcal{W}^{(1)}_{\mu\nu}[\ell^+] = -\bar{q}(y_B)\zeta m \int d x_2 \text{tr} \left[ \gamma_\mu \gamma_\beta \gamma_\nu \bar{p}_2 \gamma_\alpha T \frac{(x_B - x_2)\bar{p}_1}{(x_B - x_2)ys + i\epsilon} B^V(x_B, x_2) \right] \mathcal{P} \left( x_B - x_2 \right), \]

We are now in position to check the QED gauge invariance by contraction with the photon momentum $q_\mu$. Calculating the trace, one gets

\[ q_\mu \mathcal{W}^{(1)}_{\mu\nu} = -\bar{q}(y_B)\zeta_{\nu p_2 S^T p_1} \int d x_2 \zeta m \frac{x_B - x_2}{x_B - x_2 + i\epsilon} B^V(x_B, x_2) \neq 0, \]

if the gluonic pole is present. We now focus on the contribution from the diagram depicted on Fig. 1(b). The corresponding hadron tensor takes the form:

\[ \mathcal{W}^{(2)}_{\mu\nu} = \int d^4 k_1 d^4 k_2 \delta^{(4)}(k_1 + k_2 - q) \text{tr} \left[ \gamma_\mu F(k_1)\gamma_\nu \Phi(k_2) \right], \]
where the function $F(k_1)$ reads

$$F(k_1) = S(k_1)\gamma_{2m} \int d^4\eta_1 e^{-ik_1 \cdot \eta_1} \langle p_1, S^T | \bar{\psi}(\eta_1) g A^T_{\alpha}(0) \psi(0) | S^T, p_1 \rangle .$$

(11)

Performing the collinear factorization, we derive the expression for the factorized hadron tensor which corresponds to the diagram on Fig. 1(b):

$$\overline{W}_{\mu \nu}^{(2)} = \int dx_1 dy \left[ \delta(x_1 - x_B) \delta(y - y_B) \bar{q}(y) \gamma_{\mu} \left( \int d^4 k_1 \gamma_2 (x_1 p_1^+ - k_1^+) F(k_1) \right) \gamma_{\nu} p_2 \right].$$

(12)

After some algebra, the integral over $k_1$ in (12) can be rewritten as

$$\int d^4 k_1 \gamma_2 (x_1 p_1^+ - k_1^+) F[\gamma_+](k_1) = \frac{\hat{p}_2 \gamma_{\mu} \gamma_2}{2p_2 p_1^+} \varepsilon_{3\alpha \beta} S^T_{\mu_1} \frac{1}{x_1 + i\epsilon} \int_{-1}^1 dx_2 B^V(x_1, x_2),$$

(13)

where the parametrization (4) has been used. Taking into account (13) and calculating the Dirac trace, the contraction of the tensor $\overline{W}_{\mu \nu}^{(2)}$ with the photon momentum $q_\mu$ gives us

$$q_\mu \overline{W}_{\mu \nu}^{(2)} = \int dx_1 dy \left[ \delta(x_1 - x_B) \delta(y - y_B) \bar{q}(y) \varepsilon_{\nu \beta} S^T_{\mu_1} \right] \int_{-1}^1 dx_2 3m B^V(x_1, x_2).$$

(14)

If the function $B^V(x_1, x_2)$ is the purely real one, this part of the hadron tensor does not contribute to the imaginary part. We now study the $\overline{W}_{\mu \nu}^{(1)}$ and $\overline{W}_{\mu \nu}^{(2)}$ contributions and its role for the QED gauge invariance. One can easily obtain:

$$q_\mu \overline{W}_{\mu \nu}^{(1)} + q_\mu \overline{W}_{\mu \nu}^{(2)} = \varepsilon_{\nu \beta} S^T_{\mu_1} \bar{q}(y_B) 3m \int_{-1}^1 dx_2 B^V(x_B, x_2) \left[ \frac{x_B - x_2}{x_B - x_2 + i\epsilon} - 1 \right].$$

(15)

Assuming the gluonic pole in $B^V(x_1, x_2)$ exists, after inserting (5) into (15), one gets

$$q_\mu \overline{W}_{\mu \nu}^{(1)} + q_\mu \overline{W}_{\mu \nu}^{(2)} = 0.$$

(16)

This is nothing else than the QED gauge invariance for the imaginary part of the hadron tensor. We can see that the gauge invariance takes place only if the prescriptions in the gluonic pole and in the quark propagator of the hard part are coinciding. As we have shown, only the sum of two contributions represented by the diagrams on Fig. 1(a) and (b) can ensure the electromagnetic gauge invariance. We now inspect the influence of a “new” contribution 1(b) on the single spin asymmetry and obtain the QED gauge invariant expression for the hadron tensor. It reads

$$\overline{W}_{\mu \nu}^{(G)} = \overline{W}_{\mu \nu}^{(1)} + \overline{W}_{\mu \nu}^{(2)} = -\frac{2}{q} \varepsilon_{\nu \beta} S^T_{\mu_1} \left[ x_B p_1 \mu - y_B p_2 \mu \right] \bar{q}(y_B) T(x_B, x_B).$$

(17)

Within the lepton c.m. system, the SSA [8] related to the gauge invariant hadron tensor (17) reads

$$A^{SSA} = 2 \cos \phi \sin 2\theta T(x_B, x_B) \frac{M(1 + \cos^2 \theta)q(x_B)}{M},$$

(18)

where $M$ is the dilepton mass.

We want to emphasize that this differs by the factor of 2 in comparison with the case where only one diagram, presented on Fig. 1(a), has been included in the (gauge non-invariant) hadron tensor. Therefore, from the practical point of view, the neglecting of the diagram on Fig. 1(b) or, in other words, the use of the QED gauge non-invariant hadron tensor yields the error of the factor of two.
4. Conclusions and Discussions
The essence of this paper consists in the exploration of the electromagnetic gauge invariance of the transverse polarized DY hadron tensor. We showed that it is mandatory to include a contribution of the extra diagram which naively does not have an imaginary part. The account for this extra contribution leads to the amplification of SSA by the factor of 2. This additional contribution emanates from the complex gluonic pole prescription in the representation of the twist 3 correlator $B^V(x_1,x_2)$ which, in its turn, is directly related to the complex pole prescription in the quark propagator forming the hard part of the corresponding hadron tensor. We stress that in the previous considerations (see, for example, [11]), the $B^V$-function was always assumed to be purely real one, while the needed imaginary part was ensured by means of the specially introduced “propagator” $^1$ in the hard part of the hadron tensor. We have argued that, in addition to the electromagnetic gauge invariance, the inclusion of new-found contributions corrects by the factor of 2 the expression for SSA in the transverse polarized Drell-Yan process. Finally, we proved that the complex prescription in the quark propagator forming the hard part of the hadron tensor, the starting point in the contour gauge, the representation of $B^V(x_1,x_2)$ like (5) and the electromagnetic gauge invariance of the hadron tensor must be considered together as the deeply related items.
