Abstract

The geometric properties of sigma models with target space a Jacobi manifold are investigated. In their basic formulation, these are topological field theories - recently introduced by the authors - which share and generalise relevant features of Poisson sigma models, such as gauge invariance under diffeomorphisms and finite dimension of the reduced phase space. After reviewing the main novelties and peculiarities of these models, we perform a detailed analysis of constraints and ensuing gauge symmetries in the Hamiltonian approach. Contact manifolds as well as locally conformal symplectic manifolds are discussed, as main instances of Jacobi manifolds.

Keywords: Sigma Models; Jacobi manifolds; Topological String.

1 Introduction

The present paper is a follow-up of [1] where a non-linear sigma model with target space a Jacobi manifold has been introduced. The aim of the paper is to review the findings of [1] in order to clarify some important points which where not addressed in detail in the preceding paper. Moreover, proofs of main results, such as the dimensionality of the reduced phase space of the model and the characterisation and closure of the algebra of gauge transformations, are re-derived, overcoming some simplifying assumptions which where previously made.
The main motivation for the search of a consistent definition of a sigma model with target space a Jacobi manifold is certainly the fact that it represents a natural, non-trivial generalisation of the well known Poisson sigma model. The latter is a topological field theory which was first introduced [2, 3] in relation with two-dimensional field theories with non-trivial target space, e.g. gauge and gravity models, as well as gauged WZW models. One interesting feature of the model is its intimate relation with the geometry of the target space. Indeed, it makes it possible to unravel mathematical aspects of such manifolds by employing techniques from field theory. An example of this relation was given by Cattaneo and Felder in [4, 5] where they show that the reduced phase space of the Poisson sigma model is actually the symplectic groupoid integrating the Lie algebroid associated with the Poisson structure of the target manifold. Moreover, the model made it possible to give an alternative derivation of Kontsevich quantisation formula for Poisson manifolds, in terms of the Feynman diagrams coming from the perturbative expansion of the field theory [6]. Analogous questions, such as the geometry of the reduced phase space and the quantisation of Jacobi structures, could be addressed once the model is understood.

From a more physical point of view, another motivation for the introduction of this new model is the perspective of applying techniques from Topological Quantum Field Theory to the analysis of new string backgrounds, as well as the possibility of obtaining some useful description of known models within the framework of Jacobi manifolds, as it is the case for the Poisson setting.

The Poisson sigma model is described in terms of fields \((X, \eta)\) which are formally associated with a bundle map from the tangent bundle of a source space \(\Sigma\), a two-dimensional orientable manifold possibly with boundary, to the cotangent bundle of the target Poisson manifold \(M\). In particular, \(X\) is the base map, describing the embedding of \(\Sigma\) into \(M\), while \(\eta\) is the fibre map, an auxiliary field which is in particular a one-form on \(\Sigma\) with values in the pull-back of the cotangent bundle over \(M\). In general it is not possible to integrate out such an auxiliary field, unless the target space is a symplectic manifold. In this case the Poisson bi-vector can be inverted and the equations of motion can be solved for \(\eta\). The resulting action is that of a topological A-model [7, 8], i.e., \(S = \int_\Sigma X^*(\omega)\), where \(\omega = \Pi^{-1}\) is the symplectic form on \(M\), \(\Pi\) the Poisson bi-vector field (fulfilling the condition of zero Schouten bracket \([\Pi, \Pi]_S = 0\)) and \(X^*\) denotes the pull-back map.

Our aim in [1] was to investigate the possibility of relaxing the condition \([\Pi, \Pi]_S = 0\) to what is probably the most natural generalisation, represented by a Jacobi structure. The latter is specified by a bi-vector field \(\Lambda\) and a vector field \(E\), the so called Reeb vector field, satisfying

\[
[\Lambda, \Lambda]_S = 2E \wedge \Lambda \quad \text{and} \quad [E, \Lambda]_S = 0. \tag{1.1}
\]

The triple \((M, \Lambda, E)\) defines a Jacobi manifold. A Poisson manifold is a particular case with \(E = 0\) everywhere. Two main families of Jacobi manifolds, with all other cases being
recovered as intermediate situations\(^1\), are represented by contact and locally conformal symplectic manifolds, which we will consider later in the paper for applications of our model.

From a Jacobi structure one can construct Jacobi brackets on the algebra of functions on \(M\) with the following definition:

\[
\{f,g\}_J = \Lambda(df,dg) + f(Eg) - g(Ef).
\]

(1.2)

The latter satisfy the Jacobi identity, but unlike Poisson brackets, violate the Leibniz rule; in other words, the Jacobi bracket still endows the algebra of functions on \(M\) with a Lie algebra structure, but it is not a derivation of the point-wise product among functions. Thus, the bi-vector field \(\Lambda\) may be ascribed to the family of bi-vector fields violating Jacobi identity, such as ”twisted” and ”magnetic” Poisson structures (see for example \([10, 11]\)) which recently received some interest in relation with the quantisation of higher structures (their Jacobiator being non-trivial) and with the description of non-trivial geometric fluxes in string theory. The violation of Jacobi identity is however under control, because the latter is recovered by the full Jacobi bracket, which is alternatively defined as the most general local bilinear operator on the space of real functions \(C^\infty(M,\mathbb{R})\) which is skew-symmetric and satisfies Jacobi identity \([12]\), and this makes its study especially interesting to us.

The Jacobi sigma model generalises the construction of the Poisson sigma model via the inclusion of an additional field on the source manifold, which is necessary in order to take into account the new background vector field \(E\). The field variables of the model are represented by \((X,\eta,\lambda)\), where \(X : \Sigma \to M\) is the usual embedding map, while \((\eta,\lambda)\) are put together to give elements of \(\Omega^1(\Sigma, X^*(T^*M \oplus \mathbb{R}))\), being \(T^*M \oplus \mathbb{R} = J^1M\) the vector bundle of 1-jets of real functions on \(M\). The resulting theory is a two-dimensional topological non-linear gauge theory describing strings sweeping a Jacobi manifold. The following main results were achieved in \([1]\):

- Similarly to the Poisson sigma model, the reduced phase space can be proven to be finite-dimensional, but while for the Poisson case the dimension is \(2\text{dim}M\), for the Jacobi sigma model the dimension is \(2\text{dim}M - 2\).

- The model may be related to a Poisson sigma model with target space \(M \times \mathbb{R}\) within a ”Poissonization” procedure. The latter approach has been pursued in \([13]\) in relation with non-closed fluxes, and \([14]\) with reference to gauge symmetry.

- The auxiliary fields \((\eta,\lambda)\) can be integrated out, both for contact and locally con-formal symplectic manifolds so to get a model which is solely defined in terms of

\(^1\)It is possible to show (see for example \([9]\) Thm. 11) that a generic Jacobi manifold admits a foliation by locally conformal symplectic and/or contact leaves. Examples of Jacobi manifolds with ”nonpure” characteristic foliation, namely with leaves of odd and even dimension, i.e., contact and l.c.s. leaves may be found in \([12]\).
the field $X$ and its derivatives.

- By including a dynamical term which is proportional to the metric tensor of the target manifold, it is possible to obtain a Polyakov action. The background metric and the $B$-field are expressed in terms of the Jacobi structure. A non-zero three-form, $H = dB$, may occur, depending on the details of the model.

As already anticipated, the main purpose of this contribution, is to give an account of the progress made in our understanding of the Jacobi sigma model, both for the topological and the dynamical version. Since the matter is recent and likely to be further developed we believe it appropriate to present a detailed, self-contained review of the material already covered in [1].

The paper is organised as follows. In section 2 we present a short summary of the Poisson sigma model. In section 3 we review the notion of Jacobi manifold and Jacobi structure, and we describe the procedure of Poissonization of a Jacobi manifold $M$ yielding to a higher dimensional manifold $M \times \mathbb{R}$. Although strictly not necessary for the purposes of the present paper, the latter has played an important role in suggesting the original formulation of the model. In section 4 the action functional for the Jacobi sigma model is stated. The model in the canonical formulation is constrained, with first class constraints generating gauge transformations. In comparison with [1] the analysis of first and second class constraints is considerably enlarged and clarified in 4.1.1. Gauge transformations are implemented by generating functionals $K_{\beta, \lambda_t}$ through Poisson brackets. By identifying the gauge parameters $(\beta, \lambda_t)$ with sections of the pullback bundle $J^1M$ we will show that the algebra of gauge generators closes off-shell under milder assumptions than in [1]. To obtain this result, the notion of generalised Koszul bracket [32, 33], which extends to Jacobi manifolds the Koszul bracket defined on Poisson manifolds, has been used. In 4.1.2 the constrained phase space is reduced with respect to gauge symmetries and shown to be finite dimensional with dimension equal to $2\dim M - 2$. This result, which is the content of Theorem 4.1, was already presented in [1]. Here, thanks to a better understanding of the constrained phase-space, the proof of the theorem is improved and given for general field configurations. In section 5 we consider the model in both cases of the target space being a contact and locally conformal symplectic manifold in a general fashion. We thus discuss in more detail than in [1] noteworthy examples, such as the manifolds $SU(2)$ and $SU(2) \times S^1$ as instances of contact and LCS target spaces respectively. Finally, section 6 contains a review of the dynamical case introduced in [1]. This consists in supplementing the action of the Jacobi sigma model with a dynamical term which includes a metric tensor on the target space. It is very much inspired to the dynamical Poisson sigma model discussed in [35], with some interesting differences. The emerging model, besides being non-topological, yields a Polyakov action with background metric $g$ and $B$-field determined by the Jacobi structure involved. We do not have new results in this respect.

\footnote{Specifically, the auxiliary fields $\lambda_t$ and $\beta_i$ need not be related by the condition $\beta_i = \partial_i \lambda_t$ and $\lambda_u$ need not be zero, as invoked in [1].}
and a complete understanding of the model is still lacking, while we are presently working on it. We conclude with a final discussion of the results with remarks and perspectives.

2 Poisson sigma model

The Poisson sigma model is a two-dimensional topological field theory with target space a Poisson manifold, first introduced by Ikeda and independently by Schaller and Strobl in the context of two-dimensional gravity [3] and later widely investigated in relation with other models such as two-dimensional Yang–Mills and gravity theories, as well as in relation with deformation quantisation and branes. Related to that, we mention [6] by Cattaneo and Felder where the Poisson sigma model is used to give a physical interpretation of Kontsevich quantisation formula in terms of Feynman diagrams of the perturbative expansion of the model, and the work [4] by the same authors, in which they prove that the reduced phase space of the model is the symplectic groupoid integrating the Lie algebroid associated with the Poisson manifold, inspiring later works on the integrability of Lie algebroids [15]. A brief introduction to the topic can be found in [16].

A smooth manifold $M$ is a Poisson manifold if there exists a bi-vector $\Pi \in \Gamma(\Lambda^2 TM)$ satisfying the Jacobi identity:

$$0 = [\Pi, \Pi]_S^{ijk} = \Pi^{\ell \ell} \partial_{\ell} \Pi^{jk} + \text{cycl}(ijk),$$

(2.1)

where $[\cdot, \cdot]_S : \Lambda^p(M) \times \Lambda^q(M) \to \Lambda^{p+q-1}(M)$ is the Schouten–Nijenhuis bracket on the algebra of multivector fields on the manifold $M$. The Poisson bracket on $C^\infty(M)$ is then defined as $\{f, g\} = \Pi(df, dg)$, $f, g \in C^\infty(M)$.

Let $\Sigma$ be a two-dimensional oriented manifold, possibly with boundary, and $(M, \Pi)$ an $m$-dimensional Poisson manifold. The topological Poisson sigma model is defined by the bosonic real fields $(X, \eta)$, with $X : \Sigma \to M$ the usual embedding map and $\eta \in \Omega^1(\Sigma, X^*(T^*M))$ a one-form on $\Sigma$ with values in the pull-back of the cotangent bundle over $M$. The action of the model is given by

$$S = \int_{\Sigma} \left[ \eta_i \wedge dX^i + \frac{1}{2} \Pi^{ij}(X) \eta_i \wedge \eta_j \right], \quad i, j = 1, \ldots, \dim M$$

(2.2)

where $dX \in \Omega^1(\Sigma, X^*(TM))$ and the contraction of covariant and contravariant indices is relative to the pairing between differential forms on $\Sigma$ with values in $X^*(T^*M)$ and $X^*(TM)$, respectively. It is induced by the natural pairing between $T^*M$ and $TM$ and yields a two-form on $\Sigma$. The action is manifestly invariant under diffeomorphisms of $\Sigma$, hence it describes a topological model. In order to make the world-sheet dependence explicit in (2.2), we introduce local coordinates $u^\mu$ ($\mu = 0, 1$) on $\Sigma$ so that $dX^i = \partial_\mu X^i du^\mu$, 

5
\[ \eta_i = \eta_{\mu} du^\mu \] yielding

\[
S = \int_{\Sigma} d^2u \left[ \epsilon^{\mu\nu} \eta_{\mu} \partial_\nu X^i + \frac{1}{2} \Pi^{ij}(X) \epsilon^{\mu\nu} \eta_{\mu} \eta_{\nu} \right].
\] (2.3)

The variation of the action leads to the following equations of motion in the bulk:

\[
dX^i + \Pi^{ij}(X) \eta_j = 0,
\] (2.4)

\[
d\eta_i + \frac{1}{2} \partial_i \Pi^{jk}(X) \eta_j \wedge \eta_k = 0.
\] (2.5)

One thing to notice is that the consistency of the equations of motion requires \( \Pi(X) \), as a background field, to satisfy the Jacobi identity \(^3\).

If the manifold \( \Sigma \) has a boundary, then it is necessary to impose suitable boundary conditions such that the boundary term \( \int_{\partial \Sigma} \delta X^i \eta_i \) vanishes. Many possibilities have been considered \([17–20]\). Interestingly, these have been associated with different brane solutions when the Poisson sigma model is considered in the framework of topological string theory. Indeed, taking the restriction of the field \( X|_{\partial \Sigma} : \partial \Sigma \to N \), for some closed submanifold \( N \) (the brane), there may be different conditions for \( N \). The one usually chosen (in particular, it was used by Cattaneo and Felder in \([4]\)), is the following:

\[
\eta(u)v = 0 \quad \forall \, v \in T(\partial \Sigma), \, u \in \partial \Sigma.
\] (2.6)

The Poisson sigma model comprises a variety of models. The most obvious is the one corresponding to a trivial Poisson structure \( \Pi = 0 \), for which one simply has a BF model with action \( \int_{\Sigma} \eta_i \wedge dX^i \). An interesting non-trivial example is the case corresponding to a linear Poisson structure \( \Pi^{ij} = f^{ij} X^k \), leading to a non-Abelian BF theory. In this case, in fact, the Jacobi identity for \( \Pi \) makes \( M \) the dual of a Lie algebra with structure constants \( f^{ij} \), and \( \eta \) takes the role of a one-form connection. Other cases are two-dimensional Yang-Mills theory (which is obtained by using a linear Poisson structure and including a Casimir function of \( M \) as a non-topological term in the action), gauged Wess–Zumino–Witten models and two-dimensional gravity models. A useful review where all these models are considered as derived from the Poisson sigma model is \([21]\).

An important remark concerns the auxiliary fields \( \eta_i \), which encompass conjugate momenta of the configuration fields \( X^i \) and Lagrange multipliers. On using the equations of motion they can be integrated away, resulting in a second order action, only if the target space is a symplectic manifold. In this case, in fact, the Poisson bi-vector can be inverted to a symplectic form \( \omega \), and the resulting action is that of the so-called A-model, with action \( S = \int_{\Sigma} \omega_{ij} dX^i \wedge dX^j \). In the language of strings, this corresponds to a topological action with \( B \)-field coinciding with the symplectic two-form.

\(^3\)This can be understood by acting on (2.4) with the exterior derivative, then using again (2.4) and finally using (2.5) on the result.
We now focus on the Hamiltonian approach. Let us choose the topology of the worldsheet as $\Sigma = \mathbb{R} \times [0,1]$ (we are considering open strings), where we identify the local coordinates $(u_0, u_1)$ with time and space, respectively, $u_0 = t \in \mathbb{R}$, $u_1 = u \in I = [0,1]$. By further denoting $\beta_i = \eta t_i$, $\zeta_i = \eta u_i$, $\dot{X} = \partial_t X$ and $X' = \partial_u X$, the first order Lagrangian can be written as

$$L(X, \zeta; \beta) = \int_I du \left[ -\zeta_i \dot{X}^i + \beta_i \left( X'^i + \Pi^{ij}(X) \zeta^j \right) \right], \quad (2.7)$$

from which it is clear that $X$ and $-\zeta$ are canonically conjugate variables, with Poisson brackets

$$\{\zeta_i(u), X^j(v)\} = -\delta_i^j \delta(u-v), \quad (2.8)$$

while all the other brackets are vanishing.

Notice that, in this notation, the boundary condition (2.6) means that $\beta_{\partial I} = 0$, $\beta = \eta_t$ being the component of $\eta$ tangent to the boundary.

Since $\beta$ has no conjugate variable, it has to be considered as a Lagrange multiplier imposing the constraints

$$X'^i + \Pi^{ij}(X) \zeta^j = 0, \quad (2.9)$$

from which it follows that the Hamiltonian

$$H_\beta = -\int_I du \beta_i \left[ X'^i + \Pi^{ij}(X) \zeta^j \right] \quad (2.10)$$

is pure constraint and the constraint manifold $C$ (the space of solutions of (2.9)) can also be understood as the common zero set of the functions $H_\beta$ for all $\beta$ satisfying the boundary condition $\beta(0) = \beta(1) = 0$. This implies that the system is invariant under time-diffeomorphisms. The infinitesimal generators are the Hamiltonian vector fields associated with $H_\beta$ by the canonical Poisson bracket (2.8)

$$\xi_\beta = \{H_\beta, \cdot\} = \int_I du \left( \dot{X}^i \frac{\delta}{\delta X^i} + \dot{\zeta}_i \frac{\delta}{\delta \zeta_i} \right), \quad (2.11)$$

with

$$\dot{X}^i = -\Pi^{ij} \beta_j, \quad (2.12)$$

$$\dot{\zeta}_i = \partial_u \beta_i - \partial_i \Pi^{jk} \zeta_j \beta_k. \quad (2.13)$$

The model is also invariant under space-diffeomorphisms $f(u) \partial_u$, the latter being the Hamiltonian vector field associated with $H_\beta$ if one chooses $\beta_j = f(u) \zeta_j$ [5]. However, in order for the algebra of generators to close, one has to extend the dependence of $\beta$ according to $\beta(u) \rightarrow \beta(u, X(u))$, with $\beta = \beta_i dX^i$ the associated one-form in local coordinates. Then it is possible to check that

$$\{H_\beta, H_\tilde{\beta}\} = H_{[\beta, \tilde{\beta}]} \quad (2.14)$$
with
\[ [\beta, \tilde{\beta}] = d\langle \beta, \Pi(\tilde{\beta}) \rangle - i_{\Pi(\tilde{\beta})} d\tilde{\beta} + i_{\Pi(\beta)} d\beta \] (2.15)
the Koszul bracket among one-forms on the target manifold \( M \), which satisfies the Jacobi identity provided \( \Pi \) is a Poisson tensor. \( \langle , \rangle \) denotes the natural pairing between \( T^*M \) and \( TM \). Following \[4\], Eq. (2.15) may be extended to \( P_0\Omega^1(M) \), the latter being the algebra of continuous maps \( \beta : I \to \Omega^1(M) \), with the property \( \beta(0) = \beta(1) = 0 \), according to
\[ [\beta, \tilde{\beta}](u) = [\beta(u), \tilde{\beta}(u)]. \] (2.16)

Eq. (2.14) shows that the map \( \beta \to H_\beta \) is a Lie algebra homomorphism, the Hamiltonian constraints are first class and the Hamiltonian vector fields (2.11) generate gauge transformations. Hence, the reduced phase space of the model is defined in the usual way as the quotient \( \mathcal{G} = \mathcal{C}/H \), where \( H \) is the gauge group. It can be proven \[4\] that the reduced phase space is a finite-dimensional manifold of dimension \( 2\dim(M) \). A generalisation of this result holds true for the Jacobi sigma model, therefore we shall postpone the proof to a forthcoming section.

3 Jacobi manifolds

Jacobi brackets were first introduced by Lichnerowicz in \[23\] as a natural generalisation of Poisson brackets, such that the Leibniz rule is replaced by a weaker condition. The brackets are defined by means of a bi-linear bi-differential operator acting on the algebra of functions on a smooth manifold \( M \) as
\[ \{f, g\}_J = \Lambda(df, dg) + f(Eg) - g(Ef), \] (3.1)
where \( \Lambda \in \Gamma(\Lambda^2TM) \) is a bi-vector field and \( E \in \Gamma(TM) \) is a vector field (the Reeb vector field) on the manifold \( M \), satisfying
\[ [\Lambda, \Lambda]_S = 2E \wedge \Lambda, \quad [\Lambda, E]_S = \mathcal{L}_E \Lambda = 0, \] (3.2)
where \( \mathcal{L} \) denotes the Lie derivative operator.\(^4\) It will prove useful to write the explicit expression of these relations in coordinates:
\[ \Lambda^{pi} \partial_p \Lambda^{jk} + \text{cycl perm}\{ijk\} = E^i \Lambda^{jk} + \text{cycl perm}\{ijk\}, \] (3.3)
\[ E^k \partial_k \Lambda^{ij} - \Lambda^{kj} \partial_k E^i - \Lambda^{ik} \partial_k E^j = 0. \] (3.4)
\(^4\)In other words, the bi-vector field \( \Lambda \) fails to satisfy Jacobi identity by a term given by \( E \wedge \Lambda \), representing the Jacobiator.
Jacobi brackets are linear, skew-symmetric and satisfy Jacobi identity just like Poisson brackets. The Leibniz rule is replaced by the condition

$$\{f,gh\}_J = \{f,g\}_J h + g\{f,h\}_J + gh(Ef).$$  \hfill (3.5)

This means that the Jacobi brackets still endow the algebra of functions $\mathcal{F}(M)$ with the structure of a Lie algebra\(^5\), but, unlike the Poisson brackets, they are not a derivation of the point-wise product among functions. Jacobi brackets are a generalisation of Poisson brackets since the latter can be obtained from the former if the Reeb vector field is vanishing, $E = 0$. A Jacobi manifold $(M, \Lambda, E)$ is then defined as a smooth manifold equipped with a Jacobi structure\(^6\). Two main classes of Jacobi manifolds are represented by locally conformal symplectic manifolds (LCS) and contact manifolds. The former ones are even-dimensional manifolds endowed with a non-degenerate two-form $\omega \in \Omega^2(M)$ and a closed one form $\alpha \in \Omega^1(M)$ with the property that\(^2\)

$$d\omega + \alpha \wedge \omega = 0. \quad \hfill (3.6)$$

The latter condition is equivalent to the statement that in each local chart $U_i \subset M$ there always exists $f \in C^\infty(U_i)$ such that $\alpha$ is exact and $\omega$ is conformally equivalent to a symplectic form $\Omega$ according to:

$$\alpha = df, \quad \omega = e^{-f}\Omega. \quad \hfill (3.7)$$

Then, the global structures which qualify a LCS manifold as a Jacobi one, namely the pair $(\Lambda, E)$, are uniquely defined in terms of $(\alpha, \omega)$ as follows:

$$\iota_E \omega = -\alpha, \quad \iota_{\Lambda(\gamma)} \omega = -\gamma \quad \forall \gamma \in T^*M. \quad \hfill (3.8)$$

Globally conformal symplectic and symplectic manifolds are particular cases of LCS.

Contact manifolds are in turn odd-dimensional manifolds which are endowed with a contact structure, namely a one-form $\vartheta$ satisfying $\vartheta \wedge (d\vartheta)^n = \Omega$, where $2n + 1$ is the dimension of the manifold and $\Omega$ a volume form. The contact form is defined as an equivalence class of one-forms up to multiplication by a non-vanishing function. It is possible to endow the algebra of functions on a contact manifold with a Lie algebra structure\(^2\), which reads

$$[f, g]\vartheta \wedge (d\vartheta)^n := (n - 1)df \wedge dg \wedge \vartheta \wedge (d\vartheta)^{n-1} + (fdg - gdf) \wedge (d\vartheta)^n. \quad \hfill (3.9)$$

The latter is local by construction and satisfies Jacobi identity. It may be seen to be equivalent to the standard definition of Jacobi bracket, by implicitly defining $\Lambda$ and $E$ as

---

\(^5\)In particular a local Lie algebra, in the sense of Kirillov [24], since it holds that: supp $(\{f,g\}) \subseteq$ supp $(f) \cap$ supp $(g)$.

\(^6\)A generalisation in terms of complex line bundles can be found in [25].
follows:
\[ \iota_E (\vartheta \wedge (d\vartheta)^n) = (d\vartheta)^n \]
\[ \iota_\Lambda (\vartheta \wedge (d\vartheta)^n) = n\vartheta \wedge (d\vartheta)^{n-1}. \]  
(3.10)

The latter conditions imply\(^7\) that
\[ \iota_E \vartheta = 1, \quad \iota_E d\vartheta = 0, \]  
(3.11)
as well as
\[ \iota_\Lambda \vartheta = 0, \quad \iota_\Lambda d\vartheta = 1. \]  
(3.12)

Noteworthy examples of contact manifolds are represented by three-dimensional semi-simple Lie groups, where the contact one-form can be chosen to be one of the basis left-invariant (resp. right-invariant) one-forms on the group manifolds. Non-trivial examples of LCS manifolds may be easily constructed by considering the product \( M \times S^1 \), with \( M \) a contact manifold [27]. In Section 5.1.1 we shall consider in some detail the case of the Lie group \( SU(2) \), which has been widely studied in the literature in relation with Poisson sigma models (see, for example, [29, 30]) and we shall only sketch its LCS counterpart \( SU(2) \times S^1 \).

### 3.1 Poisson structure on \( M \times \mathbb{R} \) from \( (M, J) \)

An important result due to Lichnerowicz shows that it is possible to associate with any Jacobi manifold a higher dimensional Poisson manifold. The exact statement goes as follows

**Theorem 3.1.** [23] Given a Jacobi structure \( J(f, g) = \Lambda(df, dg) + f(Eg) - g(Ef) \) on \( M \), the product manifold \( M \times \mathbb{R} \) carries a family of equivalent Poisson structures with Poisson bi-vector \( P \) defined as
\[ P \equiv e^{-\tau} \left( \Lambda + \frac{\partial}{\partial \tau} \wedge E \right), \quad \tau \in \mathbb{R}. \]  
(3.13)

The procedure is called Poissonization of the Jacobi manifold \((M, \Lambda, E)\). For contact manifolds it is possible to check that this is actually a symplectification. Indeed, in such a case, one can define a closed 2-form \( \omega \) on \( M \times \mathbb{R} \) in terms of the contact one-form \( \vartheta \): \( \omega = d(e^\tau \pi^* \vartheta) = e^\tau (d\tau \wedge \pi^* \vartheta + d\pi^* \vartheta) \), where \( \pi : M \times \mathbb{R} \rightarrow M \) is the projection map. By using the defining properties of the contact form, it is possible to check that \( \omega \) is non-degenerate, hence symplectic.

The Poissonization procedure provides a simple recipe to obtain a Poisson bracket from a Jacobi structure and can be used to derive useful results for Jacobi manifolds. By using the projection map \( \pi \) it is possible to define Hamiltonian vector fields associated

---

\(^7\)In three dimensions they are actually equivalent statements.
with the Jacobi structure (see, for example, [9])

\[
\xi_f := \pi_* (\xi^P_{e,f}) |_{\tau=0},
\]  

(3.14)

where \(\xi^P_{e,f}\) is the Hamiltonian vector field associated with the Poisson bracket on \(M \times \mathbb{R}\) and \(\pi_* : T(M \times \mathbb{R}) \to TM\) denotes the push-forward of the projection map. This yields, for any function \(f \in \mathcal{F}(M)\)

\[
\xi_f = \Lambda(df, \cdot) + fE.
\]  

(3.15)

The map \(f \to \xi_f\) is homomorphism of Lie algebras, it being \([\xi_f, \xi_g] = \xi_{\{f,g\}}\), where the bracket \([\cdot , \cdot]\) is the standard Lie bracket of vector fields.

Theorem 3.1 may be invoked to obtain field theories on Jacobi manifolds by relying on existing models on the overlying Poisson manifold. This is achieved by the immersion \(i : M \hookrightarrow M \times \mathbb{R}\) through the identification of \(M\) with \(M \times \{0\}\). It applies in particular to the Poisson sigma model and it is the approach followed in the first part of [1] (also see [13, 14]). However, as we will see, it is not the choice we have made for the present paper.

4 Jacobi sigma model

In this section, we shall analyse the Jacobi sigma model, first introduced in [1] (also see [13]) as a generalisation of the Poisson sigma model. Although the defining action functional may be justified in terms of a Poissonization of the target Jacobi manifold and further reduction of the correspondent Poisson sigma model living on \(M \times \mathbb{R}\), it has been shown in [1] that an independent formulation can be given. We shall adhere to the latter approach in this paper. Therefore the following coordinates-independent reformulation of the definition already given in [1] may be stated

**Definition 4.1.** Let \((M, \Lambda, E)\) be a \(n\)-dimensional Jacobi manifold. The Jacobi sigma model with source space a two-dimensional manifold \(\Sigma\) with boundary \(\partial \Sigma\) and target space \(M\) is defined by the action functional

\[
S[X, (\eta, \lambda)] = \int_{\Sigma} \langle \eta, (dX) \rangle + \frac{1}{2} \langle \eta, (\Lambda \circ X)\eta \rangle + \lambda \wedge (E \circ X)\eta
\]  

(4.1)

with boundary condition \(\eta(u)v = 0, u \in \partial \Sigma, v \in T(\partial \Sigma)\).

The field configurations are represented by \(X, (\eta, \lambda)\) with \(X : \Sigma \to M\) the base map and \((\eta, \lambda) \in \Omega^1(\Sigma, X^* (J^1M))\), where \(J^1M = T^*M \oplus \mathbb{R}\) is the 1-jet bundle of real functions on \(M\).

Sections of the latter are isomorphic as a \(C^\infty(M)\)-module to the algebra of one-forms
\[ \Gamma_0(M) := \{ e^\tau(\alpha + f d\tau) | \alpha \in \Omega^1(M), f \in C^\infty(M), \tau \in \mathbb{R} \} \subseteq \Omega^1(M \times \mathbb{R}) \]  

(4.2)

which is closed with respect to the Koszul bracket of the Poissonised manifold. The map \( \langle \cdot, \cdot \rangle \) establishes a pairing between differential forms on \( \Sigma \) with values in the pull-back \( X^*(T^*M) \) and differential forms on \( \Sigma \) with values in \( X^*(TM) \). It is induced by the natural one between \( T^*M \) and \( TM \) and yields in this case a two-form on \( \Sigma \). Then the action may be rewritten as (cfr. [1])

\[ S(X, \eta, \lambda) = \int_{\Sigma} \left[ \eta_i \wedge dX^i + \frac{1}{2} \Lambda^{ij}(X) \eta_i \wedge \eta_j - E^i(X) \eta_i \wedge \lambda \right]. \]  

(4.3)

On comparing with the action of the Poisson sigma model (2.2) one important difference is the presence of a new auxiliary field, \( \lambda \), which, loosely speaking, is a one-form on the source manifold \( \Sigma \) but a scalar on the Jacobi manifold. This is a consequence of the fact that the Jacobi bracket is expressed in terms of a bi-differential operator, not a bi-vector field. Therefore \( \lambda \) is needed in order to take into account the presence of the Reeb vector field \( E \).

The variation of the action, together with the boundary condition for \( \eta \) in Def. 4.1, gives the following equations of motion

\[ dX^i + \Lambda^{ij} \eta_j - E^i \lambda = 0, \]  

(4.4)

\[ d\eta_i + \frac{1}{2} \partial_i \Lambda^{jk} \eta_j \wedge \eta_k - \partial_i E^j \eta_j \wedge \lambda = 0, \]  

(4.5)

\[ E^i \eta_i = 0. \]  

(4.6)

The boundary condition for \( \eta \) ensures the vanishing of boundary terms. Consistency of the three yields another dynamical equation. In fact, on applying the exterior derivative to Eq. (4.4) we obtain

\[ \partial_k \Lambda^{ij} dX^k \wedge \eta_j + \Lambda^{ij} d\eta_j - \partial_k E^i dX^k \wedge \lambda - E^i d\lambda = 0. \]  

(4.7)

By substituting Eqs. (4.4)-(4.6) and by using the properties of a Jacobi structure, Eqs. (3.2), we finally get

\[ d\lambda = \frac{1}{2} \Lambda^{ij} \eta_i \wedge \eta_j. \]  

(4.8)

### 4.1 Canonical formulation of the model

In this section we will focus on the Hamiltonian formulation of the model, in close analogy with the procedure followed for the Poisson sigma model in Sec. 2. To this, the source manifold is chosen to be \( \Sigma = \mathbb{R} \times [0, 1] \), with local coordinates \( t \in \mathbb{R}, u \in [0, 1] \). Moreover,
by explicitly indicating the time and space components, the one-forms \(dX, \eta\) and \(\lambda\) shall be locally represented as 
\[
dX = \dot{X} dt + X' du, \quad \eta = \beta dt + \zeta du, \quad \lambda = \lambda_t dt + \lambda_u du, \quad \text{with} \quad \lambda_t, \lambda_u \text{ scalar fields},
\]
while \(\dot{X}, X'\) and \(\beta, \zeta\) carrying an extra index on (the pull-back of) the target manifold \(M\). Note that the boundary condition in definition 4.1 results in \(\beta \partial_\Sigma = 0\), just like for the Poisson sigma model, while there is no boundary condition for \(\lambda\) deriving from the variation of the action. We shall discuss this issue later.

With the notation chosen, the Lagrangian of the model acquires the form
\[
L = \int_I du \left[ -\dot{X}^i \zeta_i + \beta_i \left( X'^i + \Lambda^{ij} \zeta_j - E^i \lambda_u \right) + \lambda_t \left( E^i \zeta_i \right) \right], \tag{4.9}
\]
with equations of motion
\[
\begin{align*}
\dot{X}^i &= -\Lambda^{ij} \beta_j + E^i \lambda_t \\
\dot{\zeta}_i &= \beta'_i - \partial_i \Lambda^{jk} \beta_j \zeta_k - \partial_i E^j \zeta_j \lambda_t + \partial_i E^j \beta_j \lambda_u, \tag{4.10}
\end{align*}
\]
\[
\begin{align*}
X'^i + \Lambda^{ij} \zeta_j - E^i \lambda_u &= 0 \\
E^i \zeta_i &= 0 \\
E^i \beta_i &= 0. \tag{4.11}
\end{align*}
\]
The evolutionary equations are, therefore, represented by Eqs. (4.10), involving time derivatives, while Eqs. (4.11) represent constraints. In the following we perform a detailed analysis of the emergence and nature of constraints in the Hamiltonian approach.

### 4.1.1 Dirac analysis of constraints

From the Lagrangian (4.9) the Hamiltonian is seen to be
\[
H_0 = - \int_I du \beta_i \left( X'^i + \Lambda^{ij} \zeta_j - E^i \lambda_u \right) + \lambda_t \left( E^i \zeta_i \right), \tag{4.12}
\]
with \(\pi_i = \delta L / \delta \dot{X}^i = -\zeta_i\) the conjugate momenta for the field \(X^i\), while the conjugate momenta of all other fields are zero. The theory is therefore constrained. We shall perform the analysis à la Dirac, referring to standard textbooks for a detailed description of the procedure. \(^8\)

\[
\pi_{\beta_i} = 0, \quad \pi_{\lambda_u} = 0, \quad \pi_{\lambda_t} = 0 \tag{4.13}
\]

\(^8\)Shortly, we recall that primary constraints are those which emerge from the Lagrangian, without using the equations of motion. They identify a submanifold of the original carrier space of the dynamics, \(\mathcal{C}_1 \subset \mathcal{C}_0\). Secondary constraints are all subsequent constraints, obtained by the request that primary constraints be preserved along the motion. They further constrain the motion to some \(\mathcal{C}_2 \subset \mathcal{C}_1\). The process is iterated by imposing conservation of new constraints (tertiary, ..., n-ary, ...) at each step, until the true manifold of the motion, \(\mathcal{C}_n \subset \mathcal{C}_{n-1} \subset \cdots \subset \mathcal{C}_0\), is found. The term "secondary constraints" is then used for all, except for primary constraints.
which have to be added to the Hamiltonian $H_0$. The unconstrained phase space of the model may be identified as the infinite-dimensional manifold $T^*P(M \times \mathbb{R}^m \times \mathbb{R} \times \mathbb{R})$ with $P(N)$ denoting the space of maps from the source space $I = [0, 1]$ to some target $N$. The configuration fields will be $X^i : I \to M$, $\beta_i : I \to \mathbb{R}^m$, $i = 1 \ldots m$, and $\lambda_t, \lambda_u : I \to \mathbb{R}$. It is possible to read off the non-zero Poisson brackets from the first order action, which yields

$$\{\pi_i(u), X^j(v)\} = \delta_i^j \delta(u - v) \quad (4.14)$$

to which we have to add those related with the extended phase space

$$\{\pi_{\beta_i}(u), \beta_j(v)\} = \delta_i^j \delta(u - v) \quad (4.15)$$

$$\{\pi_{\lambda_t}(u), \lambda_t(v)\} = \delta(u - v) \quad (4.16)$$

$$\{\pi_{\lambda_u}(u), \lambda_u(v)\} = \delta(u - v). \quad (4.17)$$

By imposing that primary constraints be preserved along the motion, $m + 2$ new constraints are obtained

$$\dot{\pi}_{\beta_i} = X'^i + \Lambda^{ij}\zeta_j - E_i^j \lambda_u := G_{\beta_i}$$

$$\dot{\pi}_{\lambda_t} = E^i \zeta_i := G_{\lambda_t}$$

$$\dot{\pi}_{\lambda_u} = E^i \beta_i := G_{\lambda_u}. \quad (4.18)$$

Hence, the initial Hamiltonian $H_0$ is itself a sum of constraints

$$H_0 = -\int du \left[ \beta_i G_{\beta_i} + \lambda_t G_{\lambda_t} \right] \quad (4.19)$$

---

Dirac classification of constraints is yet another one, which is specific of the Hamiltonian setting [31]. Here the carrier space of the dynamics is phase space, endowed with a Poisson bracket. At each step of the reduction from the unconstrained phase space $C_0$, the so called naïve Hamiltonian $H_0$ is replaced by a new one, say $H_i = H_0 + a_\mu \chi_\mu + b_\mu G_\mu$, with $\{\chi_\mu\}$ the primary constraints, and $\{G_\mu\}$ the secondary constraints which have emerged up to the step $i$. The parameters $a_\mu, b_\mu$ are also referred to as Lagrange multipliers. The process ends when all constraints, say $\psi_\mu$, are conserved, namely $\dot{\psi}_\mu = \{\psi_\mu, H_n\} \simeq 0$ on the constrained manifold $C_n$. On considering the Poisson algebra of all constraints, first class (primary and secondary) are those which close a subalgebra, i.e. $\{\psi_\mu, \psi_\nu\} = f_{\mu\nu}^\kappa \psi_\kappa \simeq 0$, whereas second class constraints obey $\{\psi_\mu, \psi_\nu\} = c_{\mu\nu}$, with $c_{\mu\nu}$ a non-degenerate matrix (second class constraints are therefore in even number). Because of that, their Lagrange multipliers, say $d_\mu$, may be completely determined according to $d_\mu = -c_{\mu\nu}\{\psi_\nu, H_0\}$ as opposed to first class ones, which are left undetermined, hence, give rise to gauge ambiguities.
Let us compute their Poisson algebra. For secondary constraints we find

\[ \{ \mathcal{G}_{\beta_j}(u), \mathcal{G}_{\beta_j}(v) \} = -\Lambda^{il} \frac{\partial}{\partial X^i(u)} \mathcal{G}_{\beta_j}(v) + \Lambda^{jl} \frac{\partial}{\partial X^l(v)} \mathcal{G}_{\beta_j}(u) \]  

(4.20)

\[ \{ \mathcal{G}_{\beta_i}(u), \mathcal{G}_{\lambda_j}(v) \} = -\Lambda^{il} \frac{\partial}{\partial X^i(u)} \mathcal{G}_{\lambda_j}(v) \]  

(4.21)

\[ \{ \mathcal{G}_{\beta_i}(u), \mathcal{G}_{\lambda_i}(v) \} = -\Lambda^{il} \frac{\partial}{\partial X^i(u)} \mathcal{G}_{\lambda_i}(v) + E^l \frac{\partial}{\partial X^l(v)} \mathcal{G}_{\beta_i}(u) \]  

(4.22)

\[ \{ \mathcal{G}_{\lambda_i}(u), \mathcal{G}_{\lambda_j}(v) \} = -E^l \frac{\partial}{\partial X^l(u)} \mathcal{G}_{\lambda_j}(v) \]  

(4.23)

Before proceeding further, we assume, without loss of generality, that a basis of vector fields on the target manifold \( M \) has been chosen such that the Reeb vector field has non-zero component only along one of the basis elements, say \( E^i = \mathcal{E} \delta^{im} \) and we shall indicate with \( a = 1, \ldots, m - 1 \) the remaining directions. Thus we compute the remaining brackets, which yield

\[ \{ \pi_{\beta_i}(u), \mathcal{G}_{\lambda_j}(v) \} = \mathcal{E} \delta^{im} \delta(u - v) \]  

(4.24)

\[ \{ \pi_{\lambda_i}(u), \mathcal{G}_{\beta_j}(v) \} = -\mathcal{E} \delta^{im} \delta(u - v) \]  

(4.25)

with all other brackets strongly zero. By repeated use of Eqs. (3.3), (3.4) in the chosen parameterization for the Reeb vector field as \( E^i = \mathcal{E} \delta^{im} \), a tedious but straightforward calculation gives an explicit expression for the Poisson brackets (4.20)-(4.23), which read

\[ \{ \mathcal{G}_{\beta_a}(u), \mathcal{G}_{\beta_b}(v) \} = [ \mathcal{G}_{\beta_i} \partial_t \Lambda^{ba} - \mathcal{G}_{\lambda_i} \Lambda^{ba} ] \simeq 0 \]  

(4.26)

\[ \{ \mathcal{G}_{\beta_a}(u), \mathcal{G}_{\lambda_i}(v) \} = 0 \]  

(4.27)

\[ \{ \mathcal{G}_{\lambda_a}(u), \mathcal{G}_{\lambda_m}(v) \} = [ \mathcal{G}_{\beta_i} \partial_t \Lambda^{ma} - \mathcal{G}_{\lambda_i} \Lambda^{ma} - \mathcal{E} \Lambda^{ak} \zeta_k ] \simeq -\mathcal{E} \Lambda^{ak} \zeta_k \]  

(4.28)

\[ \{ \mathcal{G}_{\beta_m}(u), \mathcal{G}_{\lambda_t}(v) \} = \mathcal{G}_{\beta_i} \partial_t \mathcal{E} - \mathcal{E} \delta'(u - v) \simeq -\mathcal{E} \delta'(u - v) \]  

(4.29)

\[ \{ \mathcal{G}_{\beta_a}(u), \mathcal{G}_{\lambda_a}(v) \} = -\mathcal{G}_{\lambda_a} \partial_m \Lambda^{am} \simeq 0 \]  

(4.30)

\[ \{ \mathcal{G}_{\beta_m}(u), \mathcal{G}_{\lambda_a}(v) \} = -\beta_m \Lambda^{ml} \partial_l \mathcal{E} \]  

(4.31)

\[ \{ \mathcal{G}_{\lambda_i}(u), \mathcal{G}_{\lambda_j}(v) \} = -\mathcal{E} \beta_m \partial_m \mathcal{E} = -\mathcal{G}_{\lambda_a} \partial_m \mathcal{E} \simeq 0. \]  

(4.32)

The chosen parametrization for the Reeb vector field is particularly useful because it considerably simplifies the classification of constraints as first or second class. By inspecting the rank of the matrix of Poisson brackets, it is easy to verify that the latter is always equal to four. Therefore, we may conclude that four out of \( 2m + 4 \) constraints are second class, i.e.,

\[ \pi_{\lambda_a}, \pi_{\beta_m}, \mathcal{G}_{\lambda_a}, \mathcal{G}_{\beta_m}. \]  

(4.33)

By evaluating the conservation of constraints with respect to the total Hamiltonian

\[ H_1 = H_0 + \int du \left[ a_i \pi_{\beta_i} + a_t \pi_{\lambda_t} + a_u \pi_{\lambda_u} \right] \]  

(4.34)
we may verify that no new constraints arise, but some of the Lagrange multipliers get fixed, namely
\[ a_m = \beta_m = 0, \quad a_u = \beta_a \Lambda^{ak} \zeta_k + \partial_u \lambda_t. \] (4.35)

9 The remaining \(2m\) constraints,
\[ \pi_{\beta_a}, \quad G_{\beta_a}, \quad a = 1, \ldots, m - 1 \]
\[ \pi_{\lambda_t}, \quad G_{\lambda_t} \] (4.36)
are first class, thus generating gauge transformations, with generating functional given by the linear combination
\[ K(\beta_a, \lambda_t, a_t, a_{\beta_a}) = \int du \lambda_t G_{\lambda_t} + \beta_a G_{\beta_a} + a_t \pi_{\lambda_t} + a_{\beta_a} \pi_{\beta_a}, \quad a = 1, \ldots, m - 1 \] (4.37)
and \(\beta_a, \lambda_t, a_t, a_{\beta_a}\) are gauge parameters\(^{10}\).

In order to compute the algebra of gauge generators, \(\{K(\beta, \lambda_t, a_t, a_{\beta_a}), K(\tilde{\beta}, \tilde{\lambda}_t, \tilde{a}_t, \tilde{a}_{\beta_a})\}\), we notice firstly that primary constraints in (4.37) may be ignored, because their Poisson brackets are strongly zero. Secondly, it is evident from Eq. (4.26) that, similarly to the Poisson sigma model, the algebra will only close on-shell. Therefore, in order to obtain a closed algebra off-shell we allow for the relevant gauge parameters to be functions of the fields. More precisely, given \((\beta_a, \lambda_t) \in C(I \rightarrow X^*(T^*M \oplus \mathbb{R}))\) we allow for \(\beta_a = \beta_a(u, X(u)), \lambda_t = \lambda_t(u, X(u))\). Thus, we compute
\[ \{K(\beta, \lambda_t), K(\tilde{\beta}, \tilde{\lambda}_t)\} = \int dudu' [\{(\beta_a G_{\beta_a})(u), (\tilde{\beta}_b G_{\beta_b})(u')\} + \{(\beta_a G_{\beta_a})(u), (\tilde{\lambda}_t G_{\lambda_t})(u')\} + \{(\lambda_t G_{\lambda_t})(u), (\tilde{\beta}_b G_{\beta_b})(u')\} + \{(\lambda_t G_{\lambda_t})(u), (\tilde{\lambda}_t G_{\lambda_t})(u')\}]. \] (4.38)

On using (4.14), where \(\zeta_t = -\pi_t\) we find
\[ \{(\beta_a G_{\beta_a})(u), (\tilde{\beta}_b G_{\beta_b})(u')\} = \left[ G_c \left( \beta_a \tilde{\beta}_b \partial_c \Lambda^{ba} - \beta_a \Lambda^{aj} \partial_j \tilde{\beta}_c + \tilde{\beta}_a \Lambda^{aj} \partial_j \beta_c \right) - G_i \beta_a \tilde{\beta}_b \Lambda^{ba} \right] \delta(u - u') \] (4.39)
\[ \{(\beta_a G_{\beta_a})(u), (\tilde{\lambda}_t G_{\lambda_t})(u')\} = \left( G_a E \tilde{\lambda}_t \partial_m \beta_a - G_i \beta_a \Lambda^{aj} \partial_j \tilde{\lambda}_t \right) \delta(u - u') \] (4.40)
\[ \{(\lambda_t G_{\lambda_t})(u), (\tilde{\beta}_b G_{\beta_b})(u')\} = \left( G_i \tilde{\beta}_b \Lambda^{bj} \partial_j \lambda_t - G_b E \lambda_t \partial_m \tilde{\beta}_b \right) \delta(u - u') \] (4.41)
\[ \{(\lambda_t G_{\lambda_t})(u), (\tilde{\lambda}_t G_{\lambda_t})(u')\} = G_t E (\tilde{\lambda}_t \partial_m \lambda_t - \lambda_t \partial_m \tilde{\lambda}_t) \delta(u - u'). \] (4.42)

\(^{9}\)As for the Lagrange multiplier \(a_u\), we notice that its value agrees with the equation of motion for \(\lambda_u\) which has been derived in the Lagrangian formalism, (4.8).

\(^{10}\)First class constraints have zero Poisson brackets with the total Hamiltonian, with undetermined Lagrange multipliers. Hence, they generate canonical symmetries, that is to say, gauge transformations. One main difference with respect to the Poisson sigma model is that for the latter the whole Hamiltonian is a first class constraint, hence being itself the generating function of gauge transformations. Here instead, the Hamiltonian contains second class constraints as well, which have to be subtracted in order to get the gauge generators.
This yields
\[ \{K(\beta, \lambda_t), K(\tilde{\beta}, \tilde{\lambda}_t)\} = \int du du' \left[ \mathcal{G}_t \left( \beta_a \tilde{\beta}_b \Lambda^a + \Lambda^{ij}(\tilde{\beta}_a \partial_j \beta_c - \beta_a \partial_j \tilde{\beta}_c) \right) 
+ \mathcal{E} \left( \tilde{\lambda}_t \partial_m \beta_c - \lambda_t \partial_m \tilde{\beta}_c \right) \right] \]
\[ + \mathcal{G}_t \left( \beta_a \tilde{\beta}_b \Lambda^{ab} + \Lambda^{ij}(\tilde{\beta}_a \partial_j \beta_c - \beta_a \partial_j \tilde{\beta}_c) + \mathcal{E} \left( \tilde{\lambda}_t \partial_m \lambda_t - \lambda_t \partial_m \tilde{\lambda}_t \right) \right] \] (4.43)

We now observe that a generalisation of the Koszul bracket (2.15) is available for Jacobi manifolds, which endows the set of sections of the 1-jet bundle \( J^1M \) with a Lie algebra structure [32, 33]. Given \((\alpha, f), (\beta, g)\) sections of \( J^1M \), namely \( \alpha, \beta \in \Omega^1(M), f, g \in C(M) \), the bracket reads\(^{11}\)
\[ [(\alpha, f), (\beta, g)] = \left( (L_{2\lambda} \alpha - L_{2\beta} \alpha - d(\Lambda(\alpha, \beta) + f L_E \beta - g L_E \alpha - \alpha(E) \beta + \beta(E) \alpha)), \right) \]
\[ (\{f, g\}_J - \Lambda(df - \alpha, dg - \beta)) \] (4.44)

where \( \xi_\lambda \alpha \) denotes the vector field obtained by contracting the bi-vector field \( \Lambda \) with the one-form \( \alpha \); in local coordinates it reads: \( \xi_\lambda \alpha = \alpha_i \Lambda^{ij} \partial_j \). The latter satisfies Jacobi identity, provided the manifold is a Jacobi manifold, with \( \{f, g\}_J \) the Jacobi bracket. Analogously to the Poisson sigma model, Eq. (4.44) may be extended to maps from the interval \( I \) to sections of the 1-jet bundle \( (\alpha, f) : I \rightarrow \Gamma(J^1M) \), with the property \( \alpha(0) = \alpha(1) = 0 \), according to
\[ [(\alpha, f), (\beta, g)](u) = [(\alpha, f)(u), (\beta, g)(u)]. \] (4.45)

On computing the bracket (4.44) for \((\beta, \lambda_t), (\tilde{\beta}, \tilde{\lambda}_t)\) a lengthy but straightforward calculation yields
\[ [(\beta, \lambda_t), (\tilde{\beta}, \tilde{\lambda}_t)] = (\beta, \lambda_t) \] (4.46)
with
\[ \beta = \left( \Lambda^{ij}(\beta_i \partial_j \lambda_t - \tilde{\beta}_i \partial_j \tilde{\lambda}_t) + \tilde{\beta}_i \beta_j \partial_k \Lambda^{ij} + \mathcal{E}(\lambda_t \partial_m \tilde{\beta}_k - \tilde{\lambda}_t \partial_m \beta_k) \right) 
+ \mathcal{E}(\tilde{\lambda}_t \partial_m \beta_k - \lambda_t \partial_m \tilde{\beta}_k) + (\lambda_t \beta_m - \tilde{\lambda}_t \tilde{\beta}_m) \partial_k \mathcal{E} \right) dX^k \] (4.47)
\[ \lambda_t = \left( \Lambda^{ij}(\beta_i \partial_j \lambda_t - \tilde{\beta}_i \partial_j \tilde{\lambda}_t) + \tilde{\beta}_i \beta_j \partial_k \Lambda^{ij} + \mathcal{E}(\lambda_t \partial_m \tilde{\lambda}_t - \tilde{\lambda}_t \partial_m \lambda_t) \right) (4.48)\]

Therefore, by taking into account the second class constraints, which enforce \( \beta_m = \tilde{\beta}_m = 0 \), the RHS of the Poisson bracket (4.43) may be stated in terms of (4.47),(4.48) to give
\[ \{K(\beta, \lambda_t), K(\tilde{\beta}, \tilde{\lambda}_t)\} = -K_{[(\beta, \lambda_t), (\tilde{\beta}, \tilde{\lambda}_t)]} \] (4.49)

\(^{11}\)Vaisman shows in [32] that this is nothing but the Koszul bracket (2.15) defined for the associated "Poissonized" manifold \( (M \times \mathbb{R}, P) \), with respect to which the algebra of sections of \( J^1M \) is closed.
Notice that, for $\beta_a = \partial_a \lambda_t$ and analogous expression for $\tilde{\beta}_a$, the latter further reduces to

$$\{ K(\beta, \lambda_t), K(\tilde{\beta}, \tilde{\lambda}_t) \} = -K(d\{\lambda_t, \tilde{\lambda}_t\}, \{\lambda_t, \tilde{\lambda}_t\})$$  (4.50)

which is the particular case considered in [34]. The mapping $f \rightarrow e^{\tau}(df + fd\tau)$ with $f \in C^\infty(M)$ is a Lie algebra homomorphism from the Jacobi algebra of $M$ to $\Gamma_0(M)$ defined in (4.2).

To summarise, the model exhibits first class constraints, which generate gauge transformations. Differently from the Poisson sigma model, second class constraints are present, which have to be dealt with, before analysing the algebra of gauge generators. Thanks to the bracket (4.44) the map $(\beta, \lambda_t) \rightarrow K(\beta, \lambda_t)$ is a Lie algebra homomorphism. Moreover, because of the homomorphism stated at the end of last paragraph, time-space diffeomorphisms may be explicitly related with the Hamiltonian vector fields associated with $\lambda_t$ (resp. $\lambda_u$) through the Jacobi bracket (see [1] for details).

It is to be noticed that, because of the presence of second class constraints, the Hamiltonian vector fields generating infinitesimal gauge transformations are not directly associated with the Hamiltonian, but rather with the functional $K(\beta, \lambda_t)$. They shall be explicitly worked out in the forthcoming section.

### 4.1.2 The reduced phase space

The reduced phase space of the model was proven to be finite-dimensional in [1] with the simplifying assumption that $\lambda_u$ be zero. Moreover, a detailed analysis of constraints was not performed and the structure of the constrained manifold was not completely clarified. Therefore, we shall repeat in what follows the proof of finite dimensionality of the reduced phase space in full generality.

Since the model is gauge invariant under the action of the gauge transformations generated by the flows of the Hamiltonian vector field associated with the functional $K$, we can define the reduced phase space as the quotient space $C/H$, where $H$ is the gauge group and $C$ is the constraint manifold. According to Sec. 4.1.1 the former is an infinite-dimensional manifold, which after the imposition of all constraints results to be labelled by $2m$ fields. We choose to parametrise the manifold with $X^i, \zeta_a, \lambda_u$. The quotient manifold $C/H$ is finite-dimensional. Indeed the following theorem holds.

**Theorem 4.1.** Let $(X^i, \zeta_a, \lambda_u) \in C$. The subspace of $T_{(X^i, \zeta_a, \lambda_u)}C$ spanned by the Hamiltonian vector fields $\xi_{\beta, \lambda_t}$ is a closed subspace of codimension $2\dim(M) - 2$.

**Proof.** Let us consider the subspace $S_{(X^i, \zeta_a, \lambda_u)}$ of $T_{(X^i, \zeta_a, \lambda_u)}C$ spanned by the Hamiltonian vector fields $\xi_{\beta, \lambda_t}$, associated with the functional $K(\beta, \lambda_t)$, generating infinitesimal gauge
transformations. The map \((\beta, \lambda_t) \rightarrow \xi_{\beta, \lambda_t}\), explicitly given by
\[
\delta_{\xi_k} X^i := \{K(\beta, \lambda_t), X^i\} = \Lambda^{ia} \beta_a - \mathcal{E}\delta^i_m \lambda_t \tag{4.51}
\]
\[
\delta_{\xi_k} \zeta_a := \{K(\beta, \lambda_t), \zeta_a\} = -\beta_a' + \beta_b \partial_a \Lambda^{bk} \zeta_k + \lambda_t \zeta_m \partial_a \mathcal{E} \tag{4.52}
\]
\[
\delta_{\xi_k} \zeta_m := \{K(\beta, \lambda_t), \zeta_m\} = \partial_m \Lambda^{bk} \zeta_k + \lambda_t \zeta_m \partial_m \mathcal{E} \tag{4.53}
\]
\[
\delta_{\xi_k} \lambda_u := \{K(\beta, \lambda_t), \lambda_u\} = 0 \tag{4.54}
\]
is linear. However, on the constraint manifold \(\mathcal{C}\), the last terms in the r.h.s. of (4.52) and (4.53) vanish because \(\zeta_m = 0\), moreover, \(\partial_m \Lambda^{bk} \zeta_k = \partial_m \Lambda^{bc} \zeta_c\) which is zero because of eq. (3.2). Therefore, the non-zero components of the map on the constraint manifold are given by
\[
\xi_1^i = \Lambda^{ia} \beta_a - \mathcal{E}\delta^i_m \lambda_t \tag{4.55}
\]
\[
\xi_{2,a} = -\beta_a' + \beta_b \partial_a \Lambda^{bk} \zeta_k \tag{4.56}
\]
The kernel of this linear map is empty, showing that the map is injective. To this, we have to impose that Eqs. (4.55), (4.56) be zero. The second condition yields a homogeneous linear first order ODE with initial condition \(\beta(0) = 0\), hence, \(\beta\) vanishes identically. The first one is instead an algebraic relation for which, by using the solution \(\beta = 0\) we have \(\mathcal{E}\delta_m \lambda_t = 0\) and since the Reeb vector field is nowhere vanishing it has to be \(\lambda_t = 0\). Hence, the map is injective.

Let us, therefore, consider the image space. The tangent vector \((\tilde{X}^i, \tilde{\zeta}_a)\), to a point \((X^i, \zeta_a, \lambda_u) \in \mathcal{C}\) is the solution of the linearised constraint equations
\[
\tilde{X}^i + (A^i_j - \partial_j \mathcal{E} \delta^{im} \lambda_u) \tilde{X}^j + \Lambda^{ib} \tilde{\zeta}_b = 0. \tag{4.57}
\]
where we defined \(A^i_j = \partial_j \Lambda^{ik} \zeta_k\). The tangent field has no component \(\tilde{\lambda}_u\) because of the constraint \(\mathcal{G}_{\beta_m}\). If \((\tilde{X}, \tilde{\zeta})\) is an Hamiltonian vector field, and thus it is in the image of \(\xi\), then it has to be
\[
\tilde{X}^i = \Lambda^{ib} \beta_b - \mathcal{E}\delta^{im} \lambda_t, \tag{4.58}
\]
\[
\tilde{\zeta}_a = -\beta_a' + A^b_a \beta_b. \tag{4.59}
\]
The former have to hold at each \(u\), which implies in particular \((\tilde{X}, \tilde{\zeta})\) is in the image of \(\xi\) if
\[
\tilde{X}^i(0) + \mathcal{E}(X(0)) \delta^{im} \lambda_t(0) = 0.
\]
If we introduce the matrix \(V = \hat{P} \exp[- \int A du]\) as the path-ordered exponential of \(A\), i.e. the solution of the differential equation
\[
\begin{align*}
(V^j_i)' &= -V^k_i(u) A^j_k(u) \\
V^j_i(0) &= \delta^j_i,
\end{align*} \tag{4.60}
\]
then Eq. (4.59) can be rewritten in the form

\[ \tilde{\zeta}_a(u) = -(V^{-1}(u))_b^c \partial_c [V(u)^b_c \beta_b(u)]. \]  

(4.61)

From this equation we can define the \( m - 1 \) functions

\[ p_a(u) := \int_0^u dv V(v) \tilde{\zeta}_a(v) = -\int_0^u \partial_v [V(v)^b_a \beta_b(v)], \]  

(4.62)

from which it follows that

\[ \int_I du V(u)^b_a \tilde{\zeta}_b(u) = 0. \]

Hence, we conclude that if \((\tilde{X}, \tilde{\zeta})\) is in the image of \(\xi\), then we have

\[ \tilde{X}^i(0) + E \delta^i_m (X(0)) \lambda_t(0) = 0, \quad \int_I du V(u)^b_a \tilde{\zeta}_b(u) = 0. \]  

(4.63)

Now, it is important to notice that these conditions yield \( 2m - 2 \) invariants and not \( 2m - 1 \) as it appears. Indeed, in the chosen parametrisation for the Reeb vector field, the first equation in (4.63) amounts to

\[ \tilde{X}^a(0) = 0, \quad \tilde{X}^m(0) = -\lambda_t(0). \]  

(4.64)

However, the second relation is not gauge invariant and does not fix the \( m-th \) component of \( \tilde{X} \), \( \lambda_t(0) \) not being fixed to assume any particular value. Therefore, the first of Eqs. (4.63) yields \( m - 1 \) invariant conditions. The final count of invariant conditions is then \( 2m - 2 \).

Viceversa, if we now consider \((\tilde{X}, \tilde{\zeta})\) as a tangent vector at the point \((X, \zeta, \lambda_u) \in C\) satisfying Eq. (4.63), then we show that this tangent vector is Hamiltonian if we choose \( \beta_a = -(V^{-1})^b_a p_b = -(V^{-1})^b_a \int_0^u dv V(v) \tilde{\zeta}_c(v) \). To verify the statement, let us define the vector field

\[ Y^i(u) = \Lambda^{ib}(u) \beta_b(u) - \mathcal{E}(u) \delta^i_m \lambda_t(u), \]  

(4.65)

satisfying the boundary condition \( Y^i(0) = -\mathcal{E}(0) \delta^i_m \lambda_t(0) \), with the choice

\[ \beta_a = -(V^{-1})^b_a \int_0^u dv V(v) \tilde{\zeta}_c(v). \]  

(4.66)

We will now check directly that \( Y \) satisfies the same ODE as \( \tilde{X} \) with the same boundary condition, namely it is a tangent vector field. The derivative of Eq. (4.65) with respect to \( u \) yields:

\[
Y^i = -\partial_k \Lambda^{ib} X^k (V^{-1})_b^c \int_0^u dv V_c^a \tilde{\zeta}_a - \Lambda^{ib} \left[ \partial_u (V^{-1})_b^c \int_0^u dv V_c^a \tilde{\zeta}_a + (V^{-1})_b^c V_c^a \tilde{\zeta}_a \right] + \partial_k \mathcal{E} \delta^{im} X^k \lambda_t + \mathcal{E} \delta^{im} \lambda_t'.
\]
By means of Eq. (4.8) with \( \dot{\lambda}_u = \{ K(\beta, \lambda_t), \lambda_u \} = 0 \), namely \( \lambda'_t = -\Lambda^{ib}\beta_i\zeta_b \) and the constraint equation \( X^n = -\Lambda^{ib}\zeta_b + \mathcal{E}\delta^{im}\lambda_u \) we arrive at

\[
Y'^i = \beta_b\zeta_c \left( \Lambda^{kc} \partial_k \Lambda^{ib} + \Lambda^{ik} \partial_k \Lambda^{cb} - \mathcal{E}\delta^{im}\Lambda^{lc} \right) - \Lambda^{ib}\tilde{\zeta}_b
- \partial_k \mathcal{E}\delta^{im}\Lambda^{kb}\lambda_t - \mathcal{E}\partial_m \left( \Lambda^{ib}\beta_b\lambda_u - \mathcal{E}\delta^{im}\lambda_t\lambda_u \right).
\]

where we have substituted the defining equation for \( V \) (4.60) and the explicit form of \( \beta \) Eq. (4.66). Now using the Schouten bracket (3.3) we obtain

\[
Y'^i = -\partial_k \Lambda^{ib}\tilde{\zeta}_b Y^k - \Lambda^{ib}\tilde{\zeta}_b + \partial_k \mathcal{E}\delta^{im}\lambda_a Y^k + \left( \partial_m \Lambda^{bi}\mathcal{E} - \partial_k \mathcal{E}\delta^{im}\Lambda^{kb} \right) (\zeta_b\lambda_t + \beta_b\lambda_u).
\]

Further implementing \( \mathcal{L}_E\Lambda = 0 \) we have finally

\[
\left( \partial_m \Lambda^{bi}\mathcal{E} - \partial_k \mathcal{E}\delta^{im}\Lambda^{kb} \right) \zeta_b\lambda_t = 0.
\]

The same can be shown for the last term proportional to \( \lambda_u \), so we have finally that \( Y \) satisfies the linearised constraint in Eq. (4.57) with the same boundary condition.

To conclude, we have proven that the image of \( \xi \) is the subspace spanned by \( \xi_{\beta, \lambda_t} \) modulo the \( 2m-2 \) conditions (4.63), i.e. it is a closed subspace of co-dimension \( 2m-2 \).

Therefore, similarly to the Poisson sigma model, the constraint manifold quotiented by gauge transformations results to be finite-dimensional, but of dimension equal to \( 2m-2 \), with \( m \) the dimension of the target Jacobi manifold.

### 4.2 Poissonization

In this section we review the almost one-to-one correspondence between the Jacobi sigma model described in the previous sections and the reduced model which may be obtained on the Jacobi manifold after Poissonisation.

The idea in [1] was to formulate a Poisson sigma model with target \((M \times \mathbb{R}, P)\) \( P \) being the Poisson tensor described in Theorem 3.1, and project its dynamics down to \( M \). Fig. 1 illustrates schematically the procedure.

![Figure 1: Diagrammatic summary of the reduction of the dynamics from the Poisson sigma model to the Jacobi sigma model.](image-url)
For this purpose, let us consider the Poisson sigma model with target space the Poisson manifold \((M \times \mathbb{R}, P)\) and Poisson structure \(P = e^{-X_0}\left(\Lambda + \frac{\partial}{\partial X_0} \wedge E\right)\) defined in terms of the structures of the embedded Jacobi manifold \((M, \Lambda, E)\) and \(X_0 \in \mathbb{R}\), according to Theorem 3.1. The field configurations are then \((X, \eta)\), with \(X^I = (X^i, X^0) : \Sigma \to M \times \mathbb{R}\) the usual embedding maps and \(\eta \in \Omega^1(\Sigma, X^*(T^*(M \times \mathbb{R})))\), \(\eta_I = (\eta_i, \eta_0)\). Capital indices \(I = 0, \cdots, m\) label coordinates over the Poisson manifold \(M \times \mathbb{R}\), while lowercase letters \(i = 1, \cdots, m\) shall be reserved to the Jacobi manifold \(M\). The Poisson bi-vector field in a coordinate basis \(\{\partial/\partial X^I\}\) can be written explicitly as

\[
P^{IJ} = e^{-X_0} \begin{pmatrix}
-E^1 & 
\Lambda^{ij} &  
\vdots 

E^1 & \cdots & -E^m
\end{pmatrix},
\]

(4.67)

with \(P = P^{IJ}\partial_I \wedge \partial_J\) and \(E = E^i \partial_i\).

By splitting the equations of motion, (2.4) and (2.5) in terms of target coordinates adapted to the product manifold, one obtains:

\[
dX^i + e^{-X^0} (\Lambda^{ij} \eta_j - E^i \eta_0) = 0
\]

(4.68)

\[
dX^0 + e^{-X^0} E^i \eta_i = 0
\]

(4.69)

\[
d\eta_i + \frac{1}{2} e^{-X^0} \partial_i \Lambda^{jk} \eta_j \wedge \eta_k + e^{-X^0} \partial_i E^j \eta_0 \wedge \eta_j = 0
\]

(4.70)

\[
d\eta_0 - \frac{1}{2} e^{-X^0} \Lambda^{jk} \eta_j \wedge \eta_k - e^{-X^0} E^j \eta_0 \wedge \eta_j = 0.
\]

(4.71)

We now consider the immersion \(i : M \hookrightarrow M \times \mathbb{R}\) through the identification of \(M\) with \(M \times \{0\}\). The reduced dynamics on \(M\) is thus obtained by posing \(X^0 = 0\). This yields

\[
dX^i + \Lambda^{ij} \eta_j - E^i \eta_0 = 0
\]

\[
E^i \eta_i = 0
\]

\[
d\eta_i + \frac{1}{2} \partial_i \Lambda^{jk} \eta_j \wedge \eta_k + \partial_i E^j \eta_0 \wedge \eta_j = 0
\]

(4.72)

\[
d\eta_0 - \frac{1}{2} \Lambda^{jk} \eta_j \wedge \eta_k = 0.
\]

On identifying \(\eta_0\) with \(\pi^*\lambda\), \(\pi : M \times \mathbb{R} \to M\) being the projection map, it is immediate to verify that the reduced dynamics coincides with the one obtained from the action functional in Eq. (4.3).
However, it is important to remark that the two models are not completely equivalent. In fact, the reduced sigma model inherits an additional boundary condition for the field $\lambda_t$ which comes from $\eta_{t|\partial\Sigma} = 0$ for the Poissonised sigma model. More precisely, upon performing the splitting of the world-sheet as $\Sigma = \mathbb{R} \times I$ the additional boundary condition requires $\lambda_{t|\partial I} = 0$ other than $\beta_I = 0$, a condition which is unnecessary for the model described by the action (4.3). This makes a difference in the analysis of the gauge transformations of the two models, although it is always possible to add this condition by hand if one wants to recover a complete equivalence between the two models.

5 Contact and LCS manifolds

In this section we will consider in some detail two main classes of target spaces for the Jacobi sigma model, that is contact and locally conformally symplectic manifolds. As a first application, we shall show that for both cases an interesting result can be stated, which concerns the possibility of integrating out the auxiliary momenta and obtain a second order formulation of the action functional, solely expressed in terms of the embedding maps $X^i$ and their derivatives.

In general, it is not possible to integrate the auxiliary fields away so to obtain a second order action. As we already recalled in Sec. 2, for the Poisson sigma model this is possible only when the target space is a symplectic manifold. In that case the Poisson bi-vector can be inverted and the equations of motion can be solved for $\eta$. We shall see in the following that the situation is different for the Jacobi sigma model, both for contact and LCS target.

5.1 Integration on contact manifolds

Let us start by considering $M$ as a $(2n + 1)$-dimensional contact manifold with contact one-form $\vartheta$ satisfying $\vartheta \wedge (d\vartheta)^n \neq 0$ at every point. The Jacobi structure can then be obtained from (3.10), or, equivalently, (3.11)-(3.12). Let us consider the equations of motion, represented by (4.4)-(4.6), (4.8). Thanks to the relations satisfied by the contact form, Eqs. (3.11), (3.12), the former can be solved for $\eta$ and $\lambda$. In fact, on multiplying (4.4) by $\vartheta_i$ and summing, we obtain

$$\vartheta_i (dX^i + \Lambda^{ij} \eta_j - E^i \lambda) = \vartheta_i dX^i - \lambda = 0,$$

from which

$$\lambda = \vartheta_i dX^i.$$

In order to obtain $\eta$ we multiply (4.4) by $(d\vartheta)_{i\bar{i}}$, and sum over $i$. Again, using the
properties of the contact form we find

\[ d\vartheta_{\ell j}(dX^i + \Lambda^{ij} \eta_j - E^i \lambda) = (d\vartheta)_{\ell i} dX^i + \delta^i_j \eta_j = 0, \]  

(5.3)

from which we obtain

\[ \eta_i = (d\vartheta)_{ij} dX^j. \]  

(5.4)

Thus, we may conclude that the auxiliary fields can be completely integrated away. Substituting (5.2)-(5.4) back into the action (4.3) we find the following second order action

\[ S_2 = -\frac{1}{2} \int_\Sigma (d\vartheta)_{ij} dX^i \wedge dX^j = -\frac{1}{2} \int_\Sigma X^* (d\vartheta) \]  

(5.5)

where in the second equality we have restored the pull-back map in order to highlight the geometric content. The exterior derivative of the contact one-form takes the role of the \( B \)-field, which turns out to be closed for contact manifolds. Despite the analogy with the symplectic case, the latter can only be non-degenerate when appropriately restricted to submanifolds of the target space.

### 5.1.1 Topological Jacobi sigma model on \( SU(2) \)

As a main example of the model described so far, we consider the target space to be the group manifold of \( SU(2) \), bearing in mind that the procedure may be adapted to any three-dimensional semisimple Lie group. The group manifold is diffeomorphic to the sphere \( S^3 \). The contact one-form may be chosen among the basis left-invariant (resp. right-invariant) one-forms of the group, say \( \theta^i \) defined through the Maurer–Cartan one-form \( \ell^{-1} d\ell = \theta^i e_i \in \Omega^1(SU(2),\mathfrak{su}(2)) \), with \( \ell \in SU(2), e_i = i\sigma_i/2 \) the Lie algebra generators and \( \sigma_i \) the Pauli matrices. Let us choose, to be definite, the contact one form to be \( \vartheta = \theta^3 \). The latter defines a Jacobi bracket according to Eq. (3.9) it being

\[ \vartheta \wedge d\vartheta = \Omega \]  

(5.6)

with \( \Omega = \theta^1 \wedge \theta^2 \wedge \theta^3 \) the volume form on the group manifold. Therefore, the Reeb vector field and the bi-vector field \( \Lambda \) are easily determined by solving the equations

\[ \iota_E \vartheta = 1, \quad \iota_E d\vartheta = 0, \]  

(5.7)

\[ \iota_\Lambda \vartheta = 0, \quad \iota_\Lambda d\vartheta = 1. \]  

(5.8)

We obtain

\[ E = Y_3 \quad \Lambda = Y_1 \wedge Y_2 \]  

(5.9)

with \( Y_i, i = 1, \ldots, 3 \) the left invariant vector fields on the group manifold, which are dual the the one-forms \( \theta^i \) by definition. Hence, the Reeb vector field is constant and orthogonal to the distribution spanned by the bi-vector field \( \Lambda \). The action functional of the model
is given by
\[ S[\phi, (\eta, \lambda)] = \int_{\Sigma} \langle \eta, \phi^*(g^{-1}dg) \rangle + \frac{1}{2} \langle \eta, (\Lambda \circ \phi)\eta \rangle + \lambda \wedge (E \circ \phi)\eta \]  
(5.10)
with field configurations \( \phi, (\eta, \lambda) \), \( \phi : \Sigma \ni (t, u) \rightarrow g \in G \) and \( (\eta, \lambda) \in \Omega^1(\Sigma, \phi^*(T^*G \oplus \mathbb{R})) \).

We have chosen in this specific example to distinguish the exterior derivative \( d \) on the target manifold from the one on the source, \( d \). We recall the boundary condition \( \eta(u)v = 0, u \in \partial \Sigma, v \in T(\partial \Sigma) \).

The map \( \langle , \rangle \) establishes a pairing between differential forms on \( \Sigma \) with values in the pull-back \( \phi^*(T^*G) \) and differential forms on \( \Sigma \) with values in \( \phi^*(TG) \).

On identifying the tangent space \( TG \) with \( G \times g \) and \( T^*G \) with \( G \times g^* \) we may write
\[ \phi^*(g^{-1}dg) = (g^{-1}\partial_t g)^i e_i dt + (g^{-1}\partial_u g)^i e_i du = A^i(t, u)e_i dt + J^i(t, u)e_i du \]  
(5.11)
where we have introduced the notation
\[ (g^{-1}\partial_t g)^i = A^i, \quad (g^{-1}\partial_u g)^i = J^i \]  
(5.12)
with \( \{e_i\} \) a basis in the Lie algebra. Analogously
\[ \eta = \eta_{ij}e^j dt + \eta_{uj} e^j du := \beta_j e^j dt + \zeta_j e^j du \]  
(5.13)
\[ \lambda = \lambda_t dt + \lambda_u du \]  
(5.14)
with \( \eta_{ij} = \beta_j, \eta_{uj} = \zeta_j \) and \( \{e^i\} \) a dual basis in \( g^* \). Then the action is rewritten as
\[ S[g, (\eta, \lambda)] = \int_{\Sigma} \eta_i \wedge \phi^*(g^{-1}dg)^i + \frac{1}{2} \Lambda^{ij} \eta_i \eta_j + \lambda \wedge E^i \eta_i \]
\[ = \int_{\Sigma} (\beta_i J^j - \zeta_i A^j + \Lambda^{ij} \beta_i \zeta_j + \lambda_t E^j \zeta_j - \lambda_u E^j \beta_j) du dt \]  
(5.15)
and we have renamed the map \( \phi \) with \( g \), to simplify the notation.

Let us now derive the equations of motion. By varying the action with respect to the fields \( \zeta, \beta, g, \lambda_t, \lambda_u \) we find
\[ A^j = -\Lambda^{jl} \beta_l + \lambda_t E^j \]  
(5.16)
\[ J^j = -\Lambda^{jl} \zeta_l + \lambda_u E^j \]  
(5.17)
\[ \partial_t \zeta_j = -(\beta_k J^l - \zeta_k A^l)c_k^j + \partial_u \beta_j \]  
(5.18)
\[ E^j \zeta_j = E^j \beta_j = 0 \]  
(5.19)
where we have used, to derive the third equation,

\[
(\delta J)^j = (g^{-1} \partial_u g)^l (g^{-1} \delta g)^k c^j_{lk} + \delta_u (g^{-1} \delta g)^j \tag{5.20}
\]

\[
(\delta A)^j = (g^{-1} \partial_t g)^l (g^{-1} \delta g)^k c^j_{lk} + \delta_t (g^{-1} \delta g)^j \tag{5.21}
\]

and \(c^j_{lk}\) are the structure constants of the Lie algebra \(su(2)\). Let us notice that, with the parameterisation chosen for the source manifold \(\Sigma\), the evolutionary equations are the first and the third one, involving time derivatives, whereas the others are constraints.

In order to make contact with Eqs. (4.4)-(4.6) previously derived for a generic target space, we may write Eqs. (5.16)-(5.19) in compact form

\[
\phi^* (g^{-1} d g)^j + \Lambda^l \eta_l - \lambda E^j = 0 \tag{5.22}
\]

\[
d\eta_j + \eta_k \wedge \phi^* (g^{-1} d g)^l c^k_{lj} = 0 \tag{5.23}
\]

\[
E^j \eta_j = 0. \tag{5.24}
\]

The first and last one match respectively Eqs. (4.4), (4.6), once we have identified \(X^i\) with the local coordinates describing the map \(\phi\) in a chart. The second equation needs an intermediate step: we obtain \(\phi^* (g^{-1} d g)^j\) from (5.22) and replace it in (5.23). We find

\[
d\eta_j + \eta_k \wedge (\Lambda^{lm} \eta_m + \lambda E^l) c^k_{lj} = 0 \tag{5.25}
\]

Then we observe that

\[
\Lambda^{lm} c^k_{lj} = \frac{1}{2} (\mathcal{L}_{Y_j} \Lambda)^{mk} \quad \text{and} \quad E^l c^k_{lj} = -(\mathcal{L}_{Y_j} E)^k \tag{5.26}
\]

so that Eq. (5.25) becomes

\[
d\eta_j + \frac{1}{2} (\mathcal{L}_{Y_j} \Lambda)^{km} \eta_k \wedge \eta_m - (\mathcal{L}_{Y_j} E)^k \eta_k \wedge \lambda = 0 \tag{5.27}
\]

and this is exactly Eq. (4.5).

The Lagrangian may also be recast in the following form

\[
L[g, \eta, \lambda] = \int_I du \left[ -\zeta_i A^i + \beta_i \left( J^i + \Lambda^{ij} \zeta_j - \lambda_u E^i \right) + \lambda_t E^j \zeta_j \right] \tag{5.28}
\]

with \(A^i\) playing now the role of velocities. The action is already in its first order form, with Hamiltonian

\[
H_0 = -\int_I du \left[ \beta_i \left( J^i - \Lambda^{ij} \pi_j - \lambda_u E^i \right) + \lambda_t E^j \zeta_j \right] \tag{5.29}
\]

and

\[
\pi_i = \frac{\delta L}{\delta A^i} = -\zeta_i \tag{5.30}
\]
being the only non-zero momenta, whereas
\[ \pi_{\beta_i} = \pi_{\lambda t} = \pi_{\lambda u} = 0. \]  
(5.31)

The latter are primary constraints, which we add to the Hamiltonian to get
\[ H_1 = -\int du \left[ \beta_i \left( J^i - \Lambda^{ij} \pi_j - \lambda_u E^u \right) + \lambda_t E^j \zeta_j + a_u \pi_{\lambda u} + a_t \pi_{\lambda t} + a_{\beta_i} \pi_{\beta_i} \right]. \]  
(5.32)

In view of performing the Dirac analysis of constraints, the unconstrained phase space of the model may be identified as the infinite-dimensional manifold \( T^*(P(G \times \mathbb{R}^m \times \mathbb{R} \times \mathbb{R})) \), with \( PM \) denoting the space of maps from the source space \( \Sigma \) to the target manifold \( M \). The configuration fields will be \( g : \Sigma \to G, \beta_i : \Sigma \to \mathbb{R}^m, i = i \ldots m \) and \( \lambda_u, \lambda_t : \Sigma \to \mathbb{R} \). Then, we read off the non-zero Poisson brackets from the canonical one-form
\[ \Theta = \int_I du \pi_i \phi^*(g^{-1}dg)^i \]  
(5.33)

and its exterior derivative
\[ \Omega = d\Theta = \int_I d\pi_i \wedge \phi^*(g^{-1}dg)^i - \pi_i c^i_{jk} \phi^*(g^{-1}dg)^j \wedge \phi^*(g^{-1}dg)^k \]  
(5.34)

This yields the non-zero Poisson brackets to be
\[ \{ \pi_i(u), \pi_j(v) \} = c^k_{ij} \pi_k \delta(u - v) \]  
(5.35)
\[ \{ \pi_i(u), g(v) \} = i g \sigma_i \delta(u - v) \]  
(5.36)
\[ \{ g(u), \bar{g}(v) \} = 0 \]  
(5.37)

(in particular \( \{ \pi_i, J^j \} = J^k c^j_{ki} \delta(u - v) + \delta^j_i \delta'(u - v) \)), to which we add those on the extended phase space
\[ \{ \pi_{\beta_i}(u), \beta_j(v) \} = \delta^j_i \delta(u - v) \]  
(5.38)
\[ \{ \pi_{\lambda t}(u), \lambda_t(v) \} = \delta(u - v) \]  
(5.39)
\[ \{ \pi_{\lambda u}(u), \lambda_u(v) \} = \delta(u - v). \]  
(5.40)

Adapting the analysis of constraints to the present case, we find the secondary constraints
\[ G_{\lambda u} = -\beta_i E^i = -\beta_3 \]  
(5.41)
\[ G_{\lambda t} = -\pi_i E^i = -\pi_3 \]  
(5.42)
\[ G_{\beta_i} = J^i - \Lambda^{ij} \pi_j - \lambda_u \delta^i_3 \]  
(5.43)
whose algebra yields

\[
\begin{align*}
\{G_{\beta a}(u), G_{\beta b}(v)\} &= \epsilon_{ab} G_{\lambda t}(u) \delta(u-v) \\
\{G_{\lambda t}(u), G_{\beta a}(v)\} &= \epsilon_{ab} G_{\beta b}(u) \delta(u-v) \\
\{G_{\lambda a}(u), G_{\beta b}(v)\} &= -\delta'(u-v) \\
\{G_{\beta a}(u), G_{\beta b}(v)\} &= J^a(u) \delta(u-v) \\
\{G_{\beta a}(u), \pi_{\lambda u}(v)\} &= \delta_{ab} \delta(u-v) \\
\{G_{\lambda u}(u), \pi_{\beta l}(v)\} &= \delta_{ab} \delta(u-v)
\end{align*}
\]

all others being zero. Therefore, from imposing the conservation of secondary constraints, we obtain

\[
\begin{align*}
\dot{G}_{\lambda u} &= a_{\beta 3} \\
\dot{G}_{\beta a} &= \beta_3 J^a - \epsilon_{ab} (\beta_b G_{\lambda t} + \lambda_t G_{\beta b}) \\
\dot{G}_{\beta 3} &= \beta_a J^a - a_u + \partial_u \lambda_t
\end{align*}
\]

yielding

\[
a_{\beta 3} = \beta_3 = 0; \quad a_u = \beta_a J^a + \partial_u \lambda_t.
\]

In agreement with the general results of Sec. 4.1.1, we can conclude that, out of the \(2n + 4 = 10\) constraints of the model, four of them are second class, namely

\[
G_{\lambda u}, \quad \pi_{\lambda u}, \quad G_{\beta 3}, \quad \pi_{\beta 3}.
\]

The dynamics is retrieved by the total Hamiltonian \(H_1\), with canonical Poisson brackets (5.35)-(5.40) and some of the Lagrange multipliers fixed by Eq. (5.53)

\[
H_1 = \int du \left[ \beta_a G_{\beta a} + \lambda_t G_{\lambda t} + a_u \pi_{\lambda u} + a_t \pi_{\lambda t} + a_{\beta a} \pi_{\beta a} \right], \quad a = 1, 2.
\]

It may be easily verified that the algebra of gauge generators

\[
K(\beta, \lambda_t) = \int du \left[ \beta_a G_{\beta a} + \lambda_t G_{\lambda t} + a_t \pi_{\lambda t} + a_{\beta a} \pi_{\beta a} \right], \quad a = 1, 2.
\]

closes according to Eq. (4.49).

To close this section we apply the results of 5.1 to the case of \(SU(2)\) for the integration of the fields \(\eta\) and \(\lambda\). The resulting action is here adapted as

\[
S_2 = -\frac{1}{2} \int_\Sigma \langle d\vartheta, (g^{-1}dg) \wedge (g^{-1}dg) \rangle,
\]
and by writing $d\vartheta$ explicitly we have

$$S_2 = -\frac{1}{2} \int_{\Sigma} \epsilon_{ab} (g^{-1}dg)^a \wedge (g^{-1}dg)^b = \int_{\Sigma} d^2 u \epsilon_{ab} A^a J^b,$$

(5.58)

with degenerate $B$-field $B_{ab} = \epsilon_{ab}$, all other components being zero.

### 5.2 Integration on locally conformal symplectic manifolds

Let us now consider a $2n$-dimensional locally conformal symplectic manifold $M$ with the non-degenerate two-form $\omega$ and closed one-form $\alpha$ satisfying (3.6), or equivalently, and especially useful for our purposes, (3.8). We have from the latter

$$\Lambda = \omega^{-1}, \quad E^i = (\omega^{-1})^{ij} \alpha_j$$

(5.59)

Therefore, by multiplying (4.4) with $(\omega)_{\ell i}$ we arrive at

$$(\omega)_{\ell i} (dX^i + \Lambda^{ij} \eta_j - E^i \lambda) = \omega_{\ell j} dX^j + \eta_\ell - \alpha_\ell \lambda = 0,$$

(5.60)

so that $\eta$ can be written as

$$\eta_\ell = -\omega_{\ell j} dX^j + \alpha_\ell \lambda.$$

(5.61)

Note that in this case, differently from contact manifolds, it is not possible to explicitly decouple $\eta$ and $\lambda$. However, on substituting (5.61), together with the second of Eqs. (5.59) into the action functional, after a few simple manipulations it is possible to verify that the terms proportional to $\lambda$ simplify out and we are left with

$$S_2 = \int_{\Sigma} \omega_{ij} dX^i \wedge dX^j = \int_{\Sigma} X^*(\omega)$$

(5.62)

where we have restored the pull-back map in the second equality. Note that this is formally of the same form as (5.5) and of the $A$-model but it differs from both cases. In particular, the role of the $B$-field is represented by the two-form $\omega$ which is non-degenerate and it is not closed since it satisfies (3.6), so in this case there is place for fluxes on the target. Obviously, if $\alpha = 0$ the manifold $M$ becomes a symplectic manifold and the theory reproduces the original $A$-model as a particular case.

### 5.3 LCS manifolds

Examples of LCS manifolds may be built, according to [27], in the following way. The starting point is a contact manifold $(M^{2n-1}, \theta)$, $n \geq 2$, with contact form $\vartheta$. The manifold $(S^1 \times M^{2n-1}, \omega)$ is LCS with non degenerate 2-form $\omega$ given by

$$\omega = \vartheta \wedge \alpha + d\vartheta$$

(5.63)
where \( \alpha \in \Omega^1(S^1) \) the volume form on the circle. Therefore we can easily construct an interesting non-trivial example by considering the product \( S^1 \times S^3 \), with \( S^3 \) the contact manifold associated with the group \( SU(2) \) previously described. The Jacobi structure \((\Lambda, E)\) can be worked out, yielding

\[
\Lambda = \omega^{-1}, \quad E = \Lambda(\alpha)
\]  

(5.64)

which, in local coordinates for the circle \( S^1 \), with \( \alpha = d\phi \) becomes

\[
\Lambda = Y_3 \wedge \partial \phi - Y_1 \wedge Y_2, \quad E = -Y_3.
\]  

(5.65)

According to [27], as a generalisation of the latter, one can consider principal bundles \((P, M^{2n-1}, U(1))\) with basis the contact manifold \( M^{2n-1} \) and structure group \( U(1) \). \( P \) may be endowed with the LCS structure (5.63) where \( \alpha \) is the volume form of the structure group \( U(1) \) and \( \theta \) a \( U(1) \) connection. If the curvature of the connection \( \psi = d\theta \) is such that \( \alpha \wedge \theta \wedge (\psi)^{n-1} \neq 0 \) (namely it defines a volume form on \( P \)), then \( \omega \) is a LCS which is not globally conformally symplectic.

The two models considered in this section are new to our knowledge; they cannot be obtained from the Poisson sigma model, unless adding additional degrees of freedom, and fully rely on the underlying Jacobi geometry of the target. The LCS model is especially interesting with respect to its property of being equivalent to a Lagrangian model on the tangent manifold TPM with a two form which is neither degenerate nor closed. In next section we shall see a dynamical generalisation of Jacobi sigma models, where this issue will be discussed again.

### 6 Dynamical Jacobi

In this section, we review a non-topological extension of the Jacobi sigma model introduced in [1], which generalises the approach proposed in [35] for the Poisson sigma model. As we already briefly discussed in Sec. 2, it is possible to add a simple non-topological term to the Poisson sigma model action, which is just a Casimir function on the target manifold, so that it does not spoil the gauge invariance. However, another modification is possible, which might have interesting string applications, in which a dynamical term containing both the metric on \( \Sigma \) and on \( M \) is considered.

The action for the dynamical model gets modified with respect to the topological action analysed so far, according to:

\[
S(X, \eta, \lambda) = \int_\Sigma \left[ \eta_i \wedge dX^i + \frac{1}{2} \Lambda^{ij}(X) \eta_i \wedge \eta_j - E^i(X) \eta_i \wedge \lambda + \frac{1}{2} (G^{-1})^{ij}(X) \eta_i \wedge \star \eta_j \right],
\]  

(6.1)

where the metric on the worldsheet \( \Sigma \), \( g = \text{diag}(1,-1) \), is implemented via the Hodge
star operator $\star$, while $G$ is a metric tensor on the target Jacobi manifold $M$.

Since $G$ is non-degenerate by definition, this allows us to integrate the auxiliary fields for a generic Jacobi manifold $M$ so to obtain a Polyakov string action for the embedding maps $X$, as we will see. In fact, the new equations of motion are

$$dX^i + \Lambda^i \eta_j - E^i \lambda + (G^{-1})^{ij} \star \eta_j = 0, \quad (6.2)$$

$$d\eta_i + \frac{1}{2} \partial_i \Lambda^j \eta_j \wedge \eta_k - \partial_i E^j \eta_j \wedge \lambda + \frac{1}{2} \partial_i (G^{-1})^{jk} \eta_j \wedge \star \eta_k = 0,$$

$$E^i \eta_i = 0. \quad (6.3)$$

Being $G$ naturally non-degenerate we can solve (6.2) for $\star \eta_j$,

$$\star \eta_j = -G_{ij} \left( dX^i + \Lambda^i \eta_k - E^i \lambda \right), \quad (6.5)$$

and obtain $\eta$ by applying the Hodge star to the latter

$$\eta_p = -\left( M^{-1} \right)^{ij} G_{ij} \left( \star dX^i - \Lambda^i \Lambda^k G_{kl} dX^l + \Lambda^i \Lambda^k G_{kl} \star E^l \lambda - E^i \star \lambda \right), \quad (6.6)$$

with $M^p_{\cdot j} = \delta^p_{\cdot j} - G_{ji} \Lambda^i \Lambda^k \Lambda^p$ a symmetric matrix, which we may assume to be non-degenerate irrespective of the rank of $\Lambda$. The action becomes then

$$S(X, \lambda) = \int_\Sigma \left[ \frac{1}{2} (M^{-1})^{ij} G_{ij} dX^i \wedge \star dX^j - \frac{1}{2} (M^{-1})^{ij} G_{ip} \Lambda^k G_{jk} dX^i \wedge dX^j \right.$$

$$- \frac{1}{2} (M^{-1})^{ij} G_{tp} \Lambda^k G_{mk} E^m \lambda \wedge dX^i + \frac{1}{2} (M^{-1})^{ij} G_{tp} \star E^i \lambda \wedge dX^i \right]. \quad (6.7)$$

In order to integrate out the remaining auxiliary field, $\lambda$, we use the inner product on the space of one-forms,

$$\int_\Sigma \star \lambda \wedge dX = - \int_\Sigma \lambda \wedge \star dX, \quad (6.8)$$

so that (6.7) $\lambda$ becomes nothing more than a Lagrange multiplier imposing the geometric constraint

$$(M^{-1})_{ij} \left( \Lambda^k G_{mk} E^m dX^i + E^i \star dX^i \right) = 0. \quad (6.9)$$

This finally leads to the result that the term proportional to $\lambda$ vanishes on-shell and we are left with the second order action

$$S = \int_\Sigma \left[ g_{ij} dX^i \wedge \star dX^j + B_{ij} dX^i \wedge dX^j \right] \quad (6.10)$$

where the metric $g$ and the $B$-field are defined in terms of $G$ and $M$ according to:

$$g_{ij} = G_{jp}(M^{-1})^{pi}, \quad B_{ij} = G_{ik}(M^{-1})^{pj} G_{pl} \Lambda^l. \quad (6.11)$$

To summarise, we have obtained a Polyakov string action, with target space a Jacobi
manifold, represented by Eq. (6.10). The Jacobi bi-vector field $\Lambda$ enters the definition of the metric and the $B$-field, while the Reeb vector field $E$ is part of the constraint equation (6.9).

6.1 Dynamical model on $SU(2)$

To give an example of the Polyakov action obtained in (6.10) we consider again the $SU(2)$ group manifold as target, so to obtain the dynamical completion to the topological model already considered in Sec 5.1.1. In particular, as a metric tensor on the target we introduce the natural Cartan–Killing metric on $SU(2)$:

$$G_{ij} = \delta_{ij}.$$  

By using $G_{ij} = \delta_{ij}$ and $\Lambda_{ij} = \epsilon^{3ij}$, the metric $g$ and $B$-field are then obtained from (6.11) as

$$g_{ij} = h_{ij} = \delta_{ij} - \frac{1}{2} \epsilon_{ik3} \delta^{kl} \epsilon_{jl3}, \quad B_{ij} = -\frac{1}{2} \epsilon_{3ij}, \quad (6.12)$$

so to have

$$S = \int_{\Sigma} \left[ h_{ij}(g^{-1}dg)^i \wedge \star(g^{-1}dg)^j - \frac{1}{2} \epsilon_{3ij}(g^{-1}dg)^i \wedge (g^{-1}dg)^j \right]. \quad (6.13)$$

From the analysis of the previous section we know that this action has to be complemented with the geometric constraint in Eq. (6.9), i.e. in this case

$$(g^{-1}dg)^3 = 0. \quad (6.14)$$

It is interesting to note the form of the background metric $h$ in (6.12). This metric has been already obtained in the context of Poisson–Lie duality of $SU(2)$ sigma models [34, 36–40] as a non-degenerate metric for the group manifold of $SB(2, \mathbb{C})$, the Borel subgroup of $SL(2, \mathbb{C})$ of upper triangular matrices with complex elements with real diagonal and unit determinant. The latter plays the role of the Poisson-Lie dual of $SU(2)$ in the Manin triple decomposition of the group $SL(2, \mathbb{C})$. Therefore, it is an interesting question to understand the possible relation between the two models. Interestingly, Poisson-Lie groups are discussed in [12] in relation with Jacobi structures. We plan to come back to this question in future investigations.

7 Discussion

Let us summarise the main aspects of the model. The Jacobi sigma model is a generalisation of the well known Poisson sigma model. It is a two-dimensional topological non-linear gauge theory describing strings moving on a Jacobi background. It can be related to a field theory with a higher dimensional target, which is a Poisson sigma model for the ‘Poissonised’ manifold $M \times \mathbb{R}$. The so called Poissonisation procedure consists in the construction of a homogeneous Poisson structure on $M \times \mathbb{R}$ from the Jacobi structure.
on the Jacobi manifold $M$. The two models may be seen to yield the same dynamics, after reduction, provided we impose extra constraints at the boundary.

We have analysed the canonical formulation of the model, which exhibits first and second class constraints, with the former generating gauge transformations. Interestingly, it is possible to establish an homomorphism between the algebra of gauge transformations and the algebra of sections of the 1-jet bundle $J^1 M$, which generalises an analogous result for the Poisson sigma model, where the role of $J^1 M$ is played by $T^* M$. The reduced phase space of the model, which is obtained as the manifold of constraints modulo gauge symmetries, has finite dimension, equal to $2 \dim M - 2$.

Two main classes of target spaces have been explicitly considered, namely contact and locally conformal symplectic manifolds. We have shown that in both cases the auxiliary fields can be integrated out and a second-order action description in terms of the sole embedding maps can be given. In the case of the Poisson sigma model, this is only possible if the target manifold is symplectic, so that the Poisson bi-vector can be inverted; in such a case the resulting theory is that of a $A$-model and the $B$-field is the symplectic two-form. For the models at hand we obtain different results: on contact manifolds the resulting $B$-field is the exterior derivative of the contact one-form, which is closed but degenerate, while for the locally conformal symplectic manifolds the $B$-field is the LCS two-form $\omega$ which is neither degenerate nor closed, allowing for the possibility of generating fluxes without the need to twist the model. A similar situation occurs for dynamical models (cfr. Eq. (6.11)). In view of the importance of fluxes in relation with string compactification, the occurrence of two-forms which are not closed in the context of LCS manifolds is, therefore, interesting and needs to be further investigated. The original $A$-model of string theory is naturally recovered from the locally conformal symplectic case when the one-form is identically vanishing. The group manifold of $SU(2)$ has been considered as an explicit example of contact manifold. As for interesting examples of LCS manifolds, we have shortly reviewed a constructive procedure due to Vaisman and shown that the manifold $SU(2) \times U(1)$ may be endowed with a Jacobi structure. Examples of Jacobi manifolds which are neither contact nor LCS may be found in [12]. They include dual algebras of Poisson–Lie groups, which we think could be of interest in the context of Poisson–Lie T–Duality. We plan to address the problem in future work.

Finally, we have reviewed a dynamical extension of the model, which is obtained by adding a metric term to the action functional. On integrating out the auxiliary fields, a Polyakov action is obtained, with a metric and $B$-field, which are explicitly written in terms of the Jacobi bi–vector field $\Lambda$. The model is supplemented by a geometric constraint which is related to the Reeb vector field.

Future directions of research include the quantisation of the model, its relation with Poisson-Lie symmetry and duality and the groupoid structure of the reduced phase space. Moreover, the possibility of having non-closed B-fields in the context of LCS manifolds, both for the topological and dynamical models, shall be further investigated.
Acknowledgements The authors are especially indebted with Fabio Di Cosmo for letting them know the work of Vaisman [32] where the Koszul bracket is extended to Jacobi manifolds. Fruitful discussions with Ivano Basile, Goffredo Chirco and Florio Ciaglia are also acknowledged, which helped clarifying many aspects of the model.
