641. Evaluation of the FilmArray Pneumonia Panel and Potential Impact of Antimicrobial Use on Patients in a Trauma and Medical Intensive Care Unit
Kathy Krupinski - Shaw, BSc; Lauren Lopez, PharmD, BCPS, BCIDP; Halle Orlinski, PharmD; Patrick Orbolt, MS, MT(ASCP); Stella Antonanza, PhD, D(ABMM); OhioHealth Laboratory Services, Columbus, Ohio; University of Toledo, Toledo, Ohio

Session: 67. New Diagnostics
Thursday, October 3, 2019: 12:15 PM

Background. Organisms causing infections of the lower respiratory tract in hospitalized patients can lead to high morbidity and mortality. Identification of the agents of pneumonia allows implementation of appropriate antimicrobial therapy and fast and accurate results are essential for the application of the correct antimicrobial regimen.

Methods. For 6 months results of quantitative bronchoalveolar lavage (Q-BALs) respiratory cultures, ordered as a standard of care for patients in our intensive care unit, were compared with the results obtained by a new multiplex molecular assay for the detection of lower respiratory tract pathogens, the FilmArray pneumonia panel (PP). The panel offers semi-quantitation of the bacterial targets that were compared with the quantitative results of the Q-BALs. Additionally, a retrospective chart review was performed to examine whether there would be any difference in the timing of appropriate antimicrobial therapy if the results of the panel were to be available for those patients. Appropriate antimicrobial therapy was determined according to the institutional protocol for treatment of patients for ventilator-associated pneumonia based on the results of the quantitative cultures.

Results. Thirty-six unique patients Q-BALs were run and of those there was 83% agreement between the panel detected resistance markers and the culture isolates susceptible. Of the 15 panels, 12 were excluded because their medical records were not available for review. Of the 24 reviewed, 8 (33.3%) would have de-escalation in antibiotic therapy and 10 (33.3%) would have escalation in antibiotic therapy. The use of PP would lead to a reduction of unnecessary antimicrobial therapy in 1/3 of the patients examined. However, quantification of organisms otherwise reported as normal flora may lead to unnecessary treatment and requires education of staff to understand the results of the assay.

Session: 67. New Diagnostics
Thursday, October 3, 2019: 12:15 PM

Background. Current diagnostic methods for Helicobacter pylori infection include fecal antigen tests. C-urea breath test, and gastric biopsy. The breath test is cumbersome and expensive, whereas tests for H. pylori need to be negative before a patient can be considered a non-carrier. Therefore, we sought to develop a highly sensitive and specific method that can detect H. pylori in stool samples.

Methods. The Singulex Clarity H. pylori antigen assay incubates diluted stool sample with capture and fluorescent-labeled detection antibodies. After incubation and wash steps, fluorescent molecules are eluted and single-molecule fluorescence measured by detected events (DE). Analytical performance was compared with a commercial EIA (Premier Platinum HpSA Plus, Meridian Bioscience, Inc.) using serial dilutions of H. pylori control (<37.500–1 ng/mL) and high positive control (signal to noise ratio >2). Clinical performance was evaluated using two cohorts, one had 10 EIA-negative and 10 EIA-positive samples and the other 13 high positives (>500 at 450/630) and 5 low positives near the EIA cutoff (0.100–0.500 at 450/630). One sample was excluded due to discordant EIA results, and three to reader flags.

Results. The lower limit of detection of the Clarity H. pylori assay was 1.7 ng/mL and the EIA 1,250 ng/mL (IU/D: 4.67 ng/mL). A high positive stool sample was detectable by the Clarity H. pylori assay diluted 1:10,000 and by the EIA 1:10,000. The Clarity H. pylori assay showed a 729-fold increase in lower limit of detection and 1,000-fold increase in endogenous antigen lower limit of detection compared with the EIA. Clarity signal ranged from 46–665 DE for EIA-negative samples and 487,484–576,747 DE for EIA-positive samples.

Conclusion. The Singulex Clarity H. pylori antigen assay may have orders of magnitude higher sensitivity than the commercial EIA and demonstrated 100% positive agreement and 100% negative agreement on detection of H. pylori antigen in human stool samples. The ultrasensitive performance of the Clarity H. pylori assay has the potential for high sensitivity and specificity to improve current diagnostic options for H. pylori infection; however, additional multicenter studies are required.

Background. The identification of causative pathogens in pneumonia can be challenging, and conventional culture methods can take up to 72 hours. However, rapid virologic tests identify organisms within hours. The BioFire FilmArray (bioMérieux, North Carolina) Pneumonia Panel was recently approved by the FDA. The multiplex PCR system identifies targets from sputum and bronchoalveolar (BAL) samples, which include 18 bacteria, 8 viruses, and 7 antibiotic resistance genes.

We propose to compare the panel to routine culture methods for the detection of respiratory pathogens in patients with pneumonia in a 794-bed teaching hospital in northwest Ohio.

Methods. We retrospectively screened all hospitalized intensive care unit patients who met clinical and radiological criteria of pneumonia using electronic medical records between November 2018 and February 2019. Adult patients who had respiratory cultures collected within 7 days were included. Repeat specimens were excluded. Routine cultures were performed using the laboratory’s standard procedure, and Pneumonia Panel testing was performed according to manufacturer instructions. Fifty-nine respiratory or 13 BAL and 46 sputum specimens were evaluated. There was no discrepancy between culture and PCR in 63% (37/59) samples. One (8%) BAL and 10 (22%) sputum specimens had additional pathogens detected by PCR. There was a discrepancy between culture and PCR in four (31%) BAL and seven (17%) sputum samples and 96.4% very major errors (VME) were detected only by the Serratia marcescens (4/59 or 7%) and Haemophilus influenzae (6/59 or 10%) species. Only one sputum culture had Legionella detected by PCR. Additionally, 17 specimens had a virus detected either alone or with another bacterial pathogen by PCR. For the resistance genes, MRC was detected by PCR but not by Modified Carbenapenem Inactivation Method (mCIM) test. The mecA gene was detected in six of seven (86%) of methicillin-resistant Staphylococcus aureus (MRSAs) isolates. CTX-M was detected in Serratia and Klebsiella pneumoniae in two samples; however, the organisms were not isolated in culture.

Conclusion. The Pneumonia Panel can identify additional bacteria that were not grown in culture. This panel can rapidly identify pathogens and potentially reduce unnecessary antibiotic use.

644. Comparative Evaluation of ETEST® ERV bioMérieux with the CLSI Broth Microdilution Method for Eravacycline MIC Determination
Veronique Sauvonnat; Corey Fyfe, MS; Diane Halimi; Roland Martelin; Gilles Zambrardi, MD; Biomerieux, La Balme Les Grottes, Rhone-Alpes, France; Tetracypha Pharmaceuticals, Watertown, Massachusetts

Session: 67. New Diagnostics
Thursday, October 3, 2019: 12:15 PM

Background. Eravacycline (XERAVA™) is a novel, FDA and EMA-approved fully-synthetic fluorocycline antibiotic developed by Tetracypha Pharmaceuticals Inc. for the treatment of complicated intra-abdominal infections (cIAI) including those caused by multidrug-resistant (MDR) pathogens that have been highlighted as urgent public health threats by the US CDC and the WHO.

The new ETEST ERV strip (MIC range 0.002 – 32 µg/mL) has been developed by bioMérieux and calibrated vs. the broth microdilution reference method (BMD) as described by the Clinical and Laboratory Standards Institute (CLSI) to determine the minimal inhibitory concentration (MIC) of eravacycline against Enterobacteriaceae and staphylococci.

The aim of the study was to compare ETEST ERV to the CLSI BMD method on a panel of 166 strains comprising 131 Enterobacteriaceae and 35 Enterococci.

Methods. Quality control was performed with the CLSI QC strains E.coli ATCC 25922 and S.faecalis ATCC 29212. The ETEST ERV strip was applied on a Mueller-Hinton agar plate previously seeded with a 0.5 McF bacterial suspension. After incubation for 16–20H at 35°C, the reading was performed using the bacteriostatic mode i.e., 80% of growth. The FDA-approved breakpoints were applied (≤0.5µg/mL for Enterobacteriaceae and ≤0.064µg/mL for Enterococci).

Results. The MIC essential agreement was 99.4% at ≤1 dilution for the whole panel and the category agreement for susceptibility was 98.8% Major Errors (1 E. coli, 2 K. pneumoniae, 1 K. aerogenes, 1 C. koseri, 1 E. faecalis), all at ≤1 dilution around the single breakpoint. No Very Major Error (VME) was observed.

Conclusion. In this study, the new ETEST ERV strip has been found to be statistically equivalent to the CLSI reference method. MIC end-points appear easier to read in comparison to the reference method. With a 15-dilution MIC range and simplicity of use, ETEST ERV could represent a valuable tool for MIC determination and an alternative to the BMD reference method. ETEST ERV will undergo clinical studies to seek FDA clearance and CE marking. For Research Use Only. The performance characteristics of this product have not yet been established.

645. Singulex Clarity Norovirus Assay (In Development) Provides Ultrasensitive Detection of Norovirus Genogroups I and II
Gipsah Dave, MS; Phoebe Katzenbach, BS; Johanna Sandlund, MD; Joel Estis, MS; Ali Mukherjee, PhD; Niak Banaz, MD; Brian Nolan, PhD; Singulex, Inc., Alameda, California

Session: 67. New Diagnostics
Thursday, October 3, 2019: 12:15 PM

Background. Detection of Norovirus Genogroups I and II using the Clarity assay diluted 1:10,000,000 and by the EIA 1:10,000. The other five targets were detected only by the PP and recorded as normal flora. The use of PP would lead to a reduction of unnecessary antimicrobial therapy in 1/3 of the patients examined. However, quantification of organisms otherwise reported as normal flora may lead to unnecessary treatment and requires education of staff to understand the results of the assay.
