Evolution and current status of the subclassification of intermediate hepatocellular carcinoma

Peng-Sheng Yi, Hong Wang, Jian-Shui Li

Abstract

The staging and treatment of intermediate hepatocellular carcinoma (HCC) remains controversial. According to the recommendations of Barcelona Clinic Liver Cancer staging system, patients with intermediate HCC are candidates for transcatheter arterial chemoembolization. However, not all patients with intermediate HCC benefit from transcatheter arterial chemoembolization. Therefore, it is meaningful to propose a novel staging system of intermediate HCC in order to allocate different treatments for different subgroups. Bolondi et al proposed the first subclassification system of intermediate HCC. Subsequently, investigators performed studies to validate the feasibility of Bolondi’s criteria and proposed several novel staging systems. The present study reviewed the literatures and provided a general overview of the evolution and current status of the subclassification of intermediate HCC. We propose to expand the indication of liver resection and add radical treatments as the first option of the treatment for patients with intermediate HCC.

Key words: Subclassification; Intermediate hepatocellular carcinoma; Treatment; Staging; Transcatheter arterial chemoembolization; Liver resection

Core tip: The present study reviewed the literatures and provided a general overview of the evolution and current status of the subclassification of intermediate hepatocellular carcinoma. We propose to expand the indication of liver resection and add radical treatments as the first option of the treatment for patients with intermediate hepatocellular carcinoma.
INTRODUCTION

Hepatocellular carcinoma (HCC) ranks the fifth cause of cancer-associated mortality worldwide, and > 50% of patients with HCC are diagnosed in China[1,2]. Considering the etiology of HCC, hepatitis C virus infection and alcohol abuse are the main causes of HCC in Western countries. However, patients in China are mainly derived from the trilogy chronic hepatitis B virus infection-liver cirrhosis-HCC onset[3]. Novel staging and treatment recommendations are critical for improving the prognosis of HCC. The Barcelona Clinic Liver Cancer (BCLC) staging system is widely accepted by investigators and endorsed by the American Association for the Study of Liver Diseases and European Association for the Study of the Liver[4]. According to the recommendations of BCLC staging system, patients with very early and initial stage HCC within the Milan criteria and without associated diseases are suitable for radical treatments, including liver transplantation, liver resection and radiofrequency ablation. Patients with intermediate HCC (BCLC B stage) are recommended to receive transcatheter arterial chemoembolization (TACE), which is a palliative treatment[5]. However, 50% of patients with HCC are diagnosed at intermediate stage when the first presentation of symptoms occur[6], and the prognosis of these patients remains unsatisfactory.

Intermediate HCC comprises heterogenous patients with varying tumor burden, liver function and performance status, and TACE cannot provide survival benefit for all these patients. The survival benefit of radical treatments for intermediate HCC has been explored in recent years. Mazzaferro et al[7] analyzed the survival of patients beyond the Milan criteria based on largest tumor size, tumor nodule and microvascular invasion (MVI). Patients beyond the Milan criteria but within the sum of largest tumor size and tumor number < 7 had comparable 5-year survival rates to those within the Milan criteria. Thus, they proposed novel criteria for selecting patients with HCC for liver transplantation, called the “up to-7 criteria”. To improve the prognosis of intermediate HCC, it is of great importance to divide these patients into subgroups and allocate feasible treatments to different subgroups. Bolondi et al[8] proposed a subclassification of intermediate HCC in 2012. The Bolondi criteria sub-divides intermediate HCC into 4 groups and provides first-line and alternative treatment options for different subgroups[8]. Numerous subsequent studies were conducted to validate or clarify this subclassification system. Certain studies demonstrated the ability of the Bolondi criteria in predicting prognosis of intermediate HCC and supported the application of this system in clinical practice[9-11]. By contrast, other studies advocated to modify this system and proposed novel subclassification systems[12-14]. To date, the staging and management of intermediate HCC remains controversial. The present review aims to provide a clear summary of the evolution and general view of current status of the subclassification of intermediate HCC.

PROPOSAL AND VALIDATION OF THE BOLONDI CRITERIA

Patients with intermediate HCC are defined as those with a single tumor > 5 cm, or with 2-3 > 3 cm in maximum diameter, or with > 3 tumors regardless of tumor size, without portal vein thrombosis and extra-hepatic metastasis[8]. Due to the varying tumor burden, liver function and physical status, patients differ significantly in terms of survival outcomes and treatment response. Bolondi et al[8] proposed to subdivide intermediate HCC into 4 subgroups: Stage B1, which comprises patients with compensated cirrhosis and preserved liver function, who have a Child–Pugh score of 5-7, are within the up to-7 criteria, and have a ECOG PS completely preserved (PS0). The treatment recommendation is controversial in this subgroup, with TACE being recommended to be the first option and liver transplantation or TACE plus ablation being considered alternative options. Stage B2 comprises patients with Child-Pugh A, who are beyond the up to-7 criteria and have good well PS (PS0). TACE or transarterial radioembolization are suggested for these patients, and sorafenib is
Thus, the Kinki Criteria appears to provide more strategies than the Bolondi criteria since even radical treatments are recommended as first option for selected patients. Criteria is simplified version and the treatment recommendations are more rational, Kinki Criteria is similar to the Bolondi criteria to certain extent, although the Kinki stages based on Child-Pugh score, the Milan criteria and the up to-seven criteria. The version of the Bolonid criteria. Intermediate HCC in this case was subclassified into 3 proposed the Kinki Criteria criteria based on a modified \cite{18} et al. Subsequently, Kudo \cite{19} and HCC lesions with the tumor criteria of exhibiting 4 tumors and 7 cm in diameter.

Concluded that the best candidates for TACE were patients with Child–Pugh grade A difference was observed in survival among continuous stages (Table 3). The authors stage B1 had better survival than stage B2, B3 and B4. However, no significant substages based on these two prognostic factors. According to this subclassification, of intermediate HCC. Therefore, the authors subdivided intermediate HCC into 4 tumors of 7 cm in diameter and Child-Pugh score were significant prognostic factors Child-Pugh grade of patients receiving TACE. They observed that presence of 4 et al \cite{17} subdivided BCLC B stage based on the tumor number, size and HCC, previous studies have attempted to modify the Bolondi criteria in recent years.

Although the feasibility of the Bolondi criteria have been validated by numerous studies, there are certain limitations of this subclassification system. First, the Bolondi criteria stratify intermediate HCC based on 4 factors, but, ECOG PS is a relatively subjective factor; thus, it is difficult to definitely evaluate it and does not discriminate between cancer or cirrhosis-associated symptoms. Second, none of the radical treatments are recommended as first option for intermediate HCC. However, recent studies have demonstrated the survival benefit of radical treatments for intermediate HCC, and liver resection and liver transplantation have been demonstrated to prolong survival in supere selective patients with intermediate HCC\cite{9,11,12}. In addition, several studies demonstrated that the subclassification of intermediate HCC was an independent prognostic factor of survival outcomes\cite{9,11,12}. In summary, Bolondi criteria can predict the prognosis of intermediate HCC to certain extent. However, additional prospective studies are required to clarify its feasibility (Table 2).

**PROPOSAL OF A NOVEL SUBCLASSIFICATION OF INTERMEDIATE HCC**

Revised and approved by the managing editor

Ciria \cite{9} performed a retrospective analysis of 80 patients with intermediate HCC, and subdivided these patients according to the Bolondi criteria. Taken together, the study revealed that the 5-year survival rate did not differ between the liver resection group and the TACE group, in the subgroups of intermediate HCC, the 5-year survival rate was higher in stage B1 when compared with stages B2 and B3-4 who had been subjected to liver resection or TACE. However, the overall survival was not significantly different among continuous substages. By multivariate analysis, total bilirubin and subclassification stages B2 and B3-4 vs B1 to be independent risk factors of survival. Ciria et al. proposed to perform liver resection for stage B1 and partial of patients at B2 and B3-4 stage when the pathological and anatomical criteria were matched. Other retrospective studies obtained similar results to those reported by Ciria et al.\cite{9}. Two previous studies did not find significant difference in survival outcomes among continuous subgroups according to the Bolondi criteria\cite{13,14}, while a previous study even reported poor survival outcomes in patients at stage B3 compared with stage B4\cite{14}. However, several studies also obtained different results compared with above studies. Various studies observed significantly different survival outcomes among continuous subgroups of patients with intermediate HCC. Therefore, they recommended that the Bolondi criteria could feasibly predicting the prognosis of intermediate HCC and advocated the allocation of such criteria in clinical practice\cite{8-13}. In addition, several studies demonstrated that the subclassification of intermediate HCC was an independent prognostic factor of survival outcomes\cite{9,11,12}. In summary, Bolondi criteria can predict the prognosis of intermediate HCC to certain extent. However, additional prospective studies are required to clarify its feasibility (Table 2).
Table 1 Bolondi criteria

2Only if Up-to-7 IN and PS0. CPT: Child Pugh score; BSC: Best supportive care; LT: Liver transplantation; SOR: Sorafenib; TACE: Transcatheter arterial chemoembolization; TARE: Transarterial radioembolization; PVT: Portal vein thrombosis; Ut-7: Up-to-7 criteria.

for intermediate HCC. However, further studies are required to clarify the predicting value of prognosis of the Kinki Criteria (Table 4). Arizumi et al[19,20] compared survival outcomes among subgroups according to the Kinki Criteria, they noticed significant differences in survival among continuous subgroups. However, no significant difference in survival between BCLC A and B1 stage or BCLC C and B3 stage was observed[19,20]. Wang et al[12] validated the feasibility of the Bolondi criteria in predicting prognosis of intermediate HCC, and they demonstrated that alpha-fetoprotein (AFP) levels > 200 ng/mL and AST levels > 40 IU/L were prognostic factors. Thus, they proposed stratifying stages B1 and B2 according to AFP levels. Stages B1 and B2 were consequently subdivided into B1a (AFP < 200 ng/mL) and B1b (AFP > 200 ng/mL) and B2a (AFP < 200 ng/mL) and B2b (AFP > 200 ng/mL), respectively. The newly proposed substaging system comprises modified B1, B2 and B3 (Table 5). Survival difference is observed among continuous substages of this modified criteria.

Recently, Lee et al[21] proposed a subclassification system similar to that of Yamakado, which was based on Child-Pugh score (A or B) and tumor size (< 5 or > 5 cm). This newly proposed subclassification system comprises 3 substages, and survival differences were observed among continuous subgroups (Table 6). Kim et al[14] compared survival outcomes in different subgroups according to the Bolondi criteria, but no significantly differences in survival among substages were observed. Thus, they proposed a novel subclassification system based on Child-Pugh score, within up to-11 and ECOG PS. Instead of the up-to-7 criteria, up-to-11 was used as a measure of tumor burden. When patients were stratified using this staging system, significantly differences in survival were observed among continuous substages of intermediate HCC following TACE treatment (Table 7). A recent study proposed a subclassification system based on the up to-7 criteria and the levels of two serum biomarkers, namely AFP and des-r-carboxy prothrombin[22]. This subclassification system subdivides BCLC B stage into B1, B2 and B3 (Table 8). Notably, B2 stage in this staging system is not clearly defined and treatment recommendation is not provided, which limits its utilization in clinical practice.

DISCUSSION

The clinicopathological characteristics of patients with intermediate HCC vary in tumor burden, liver function and physical status. The treatment and subclassification of intermediate HCC remains controversial. Therefore, it is necessary to develop a novel substaging system for intermediate HCC. Bolondi et al[8] proposed the first substaging system and provided treatment options for each substage. Subsequently, several studies investigated its feasibility, and a number of them proposed modifying this system. The Bolindi criteria subdivide intermediate HCC based on liver function, tumor burden and ECOG PS. However, ECOG PS is difficult to be objectively evaluated, and treatment recommendation does not include radical treatments, which limits the utilization of this system.

Subsequent studies proposed various novel subclassification systems. Several of them stratified intermediate HCC based on prognostic factors of survival, and reported the predicting value for survival of these systems. Notably, radical treatments were recommended as treatment options for patients with intermediate HCC[18], which may prolong short and long-term survival of intermediate HCC. However, there are various limitations of these newly proposed systems. First, all these studies were retrospective analyses of cohort of consecutive patients, thus,
| Patients (n) | Treatment | Median follow-up | Ref. | B1 | B2 | B3 | B4 | Independent risk factor of survival |
|-------------|-----------|-----------------|------|----|----|----|----|-------------------------------------|
| 80          | LR, TACE  | 28.19 mo        | Ciria et al. [9] | OS rate: 43.75%; 5-yr survival rate: 62.9% | OS rate: 40%; 5-yr survival rate (28.1%) | OS rate: 11.25%; 5-yr survival rate (28.1%) | OS rate: 5%; 5-yr survival rate (15.1%) | Total bilirubin, subclassification stages B2 and B3-4 vs B1 |
| 90          | TAE       | NR              | Scaffaro et al. [10] | Mean OS: 33.6 mo | Mean OS: 28.6 mo | Mean OS: 19.0 mo | Mean OS: 13.0 mo | NR |

LR: Liver resection; OS: Overall survival; TACE: Transcatheter arterial chemoembolization; OLT: Orthotopic liver transplantation; MELD: Model of end-stage liver disease; NR: Not reported.

Further prospective studies are required to clarify the feasibility of these systems. Second, only a few newly proposed systems provide treatment recommendations for a specific substage, resulting in difficult decision making in clinical practice.

**CONCLUSION**

Substaging and treatment of intermediate HCC remains confounded for clinicians. Since the survival benefit of radical treatments has been previously demonstrated [23,24], the present study proposes expanding the indication of radical treatments and adding radical treatments into first option for patients with intermediate HCC.
### Table 3 Yamakado criteria

| Substage | B1 | B2 | B3 | B4 |
|----------|----|----|----|----|
| Child-Pugh grade A | A | B | B |
| 4 tumors and 7 cm of maximal diameter Within | Beyond | Within | Beyond |

### Table 4 Kinki Criteria

| BCLC substage | B1 | B2 | B3 |
|----------------|----|----|----|
| Child-Pugh score 5-7 | 8-9 |
| Beyond Milan and within up-to-7 In | Out |
| Sub-substage | Curative intent | Non-curative, palliative |
| Concept of treatment strategy | Curative intent if within up-to-7 | Palliative, no treatment |
| Treatment option | Resection Ablation | DEB-TACE^1 HAIC^2 |
| Superselective c-TACE | Sorafenib^3 |
| Alternative | DEB-TACE (large, C-P 7) B-TACE^4 |
| c-TACE |

^1DEB-TACE is recommended for huge tumors that are > 6 cm; ^2HAIC is recommended for multiple tumors > 6; ^3Sorafenib is recommended for patients with liver function of Child-Pugh score 5 and 6; ^4B-TACE is recommended for fewer tumors. TACE: Transcatheter arterial chemoembolization; c-TACE: Conventional subsegmental lipiodol TACE; DEB-TACE: TACE with drug-eluting beads; B-TACE: Balloon occluded TACE; HAIC: Hepatic arterial infusion chemotherapy; BSC: Best supportive care; C-P: Child-Pugh score; BCLC: Barcelona Clinic Liver Cancer.
