Abstract: The construction of heterojunctions has been widely applied to improve the gas sensing performance of composites composed of nanostructured metal oxides. This review summarises the recent progress on assembly methods and gas sensing behaviours of sensors based on nanostructured metal oxide heterojunctions. Various methods, including the hydrothermal method, electrospinning and chemical vapour deposition, have been successfully employed to establish metal oxide heterojunctions in the sensing materials. The sensors composed with the built nanostructured heterojunctions were found to show enhanced gas sensing performance with higher sensor responses and shorter response times to the targeted reducing or oxidising gases compared with those of the pure metal oxides. Moreover, the enhanced gas sensing mechanisms of the metal oxide-based heterojunctions to the reducing or oxidising gases are also discussed, with the main emphasis on the important role of the potential barrier on the accumulation layer.

Keywords: metal oxide; heterojunctions; gas sensor; sensing mechanism; review

1. Introduction

Gas sensors based on nanostructured metal oxides have attracted significant interest over the last few decades due to their advantages of low cost, ease of fabrication, high sensor response and short response/recovery times [1–4]. Various metal oxides have been successfully assembled as gas sensors since Seiyama et al. reported their research on the gas sensing performance of the ZnO thin film in the 1960s [5,6]. According to the sensing behaviours of the metal oxides, sensing metal oxides are typically divided into two main groups: n-type metal oxides and p-type metal oxides. Normally, the resistances of the n-type metal oxides decrease (or increase) towards reducing gases such as H₂, H₂S, CO, CH₄, NH₃ and other volatile organic compounds (or oxidising gases such as NO₂, NO, O₃, SO₂, etc.), while p-type metal oxides exhibit the opposite behaviour [7,8]. The n-type metal oxides of SnO₂, TiO₂, WO₃, MoO₃, Nb₂O₅, ZnO, etc., and the p-type metal oxides of CuO, Co₃O₄, Cr₂O₃, NiO, PdO, etc., have been widely studied for their gas sensing behaviours towards both reducing and oxidising gases [9–12].

In recent years, the advancement of new technologies and methods has induced a boom in nanomaterials. Nanostructured metal oxides with various morphologies, such as nanoparticles, nanosheets, nanowires, nanorods, nanoribbons, nanofibres, nanoflowers and nanocages, have been successfully prepared through the routes of hydrothermal processing, thermal oxidation, sol-gel processing, atomic layer deposition, etc. Nanoscale metal oxides have been reported to exhibit promising gas sensing performances, benefiting from their high specific surface areas [13] and active surface states [14]. Specifically, the sensor response of the pure ZnO nanowires was ~15 towards 0.5 ppm NO₂ at a working temperature of 225 °C [15]. Other sensors based on SnO₂ nanowires [16], TiO₂ nanotubes [17], WO₃ nanoparticles [18] and Ir₂O₃ nanofibres [19] have also been found to respond to the gases of NO₂, formaldehyde, H₂S and CO, respectively. The gas sensing performances of the gas
sensors mentioned above could be further improved to better meet the demands of practical applications via compositing the metal oxide with another (different) metal oxide to form a heterojunction between them. It is noteworthy that when the main phase of a metal oxide was decorated or composited with the second phase of a different semiconductor, the interface between them was known as the structure of a heterojunction in the sensing material [20]. Reports show the specific surface area of the composite is higher than that of the pure metal oxide [21], and the modulation of the potential barrier or accumulation layer in the composite effectively improves the gas sensing behaviour [22,23]. More and more researchers have focused their attention on the studies of the high-performance sensors based on nanostructured metal oxide heterojunctions, as shown in Figure 1. For example, the ordered mesoporous WO$_3$/ZnO nanocomposites synthesised with a hydrothermal method displayed an enhanced sensor response of 168.7 to 1 ppm NO$_2$ at a working temperature of 150 °C, over 10 times higher than that of the pure WO$_3$ [24]. Moreover, the sensor response of CeO$_2$ nanostructures modified with NiO was reported to be ~1570, much higher than that of the pure CeO$_2$ (139). The response time and the recovery time of the composite was 15 s and 19 s, respectively, which is also shorter than that of the pure CeO$_2$ (96 s/118 s) [25]. Therefore, the construction of heterojunctions could be a successful method to improve the gas sensing performances of sensors based on metal oxides.

![Number of published papers](image)

**Figure 1.** The number of the published papers on nanostructured metal oxide heterojunctions for high-performance gas sensors during 2009–2020 as obtained from the Web of Science. The words “nanostructured metal oxide heterojunctions” or “high-performance gas sensors” were keyed into the “topic” search box.

As reported, there have been different kinds of heterojunctions assembled to improve the gas sensing performances of metal oxides, such as n-n, n-p, p-n or p-p heterojunctions [26–29]. Note that, in this paper, the type of heterojunction is defined according to the dominant material or the main phase in the composite [30,31]. Accordingly, an n-p heterojunction is formed when the main phase of an n-type metal oxide is modified with a second phase of a p-type semiconductor. Similarly, a p-n heterojunction is established through compositing a p-type metal oxide with an n-type semiconductor. An n-n (or p-p) heterojunction would also be constructed if an n-type (p-type) metal oxide is decorated with a different n-type (p-type) semiconductor in the composite. For example, CuO-decorated ZnO or ZnO-decorated WO$_3$ are the typical n-p or n-n heterojunctions. The ZnO-decorated CuO or NiO-decorated CuO are defined as the p-n or p-p heterojunctions. With the development in the techniques to synthesise nanomaterials, it is facile to construct heterojunctions in composites composed of metal oxides. The metal oxide-based heterojunctions have been successfully established through various combined technologies, such as the thermal oxidation [28], hydrothermal method [32], electrospinning [33,34], chemical
vapour deposition (CVD) [35], pulsed laser deposition (PLD) [36], the co-precipitation method [37] and the solvothermal method [38]. For example, the hydrothermal method was reported to effectively prepare the ZnO/SnO$_2$ [39] and the NiO/SnO$_2$ composites [32]. The difference in the Fermi levels of the two metal oxides in the obtained composite would lead to the formation of the potential barrier at their interfaces, an important factor for improving sensing property of the gas sensor based on heterojunctions. The hydrothermal method combined with CVD was also used by Li et al. to establish heterojunctions composed of vertically aligned MoS$_2$/ZnO nanowires [40]. SnO$_2$-CuO heterojunctions were successfully constructed via electrospinning [41]. Their results clearly indicated that the sensor response of the sensor based on the MoS$_2$/ZnO nanowires or the SnO$_2$-CuO heterojunctions was highly improved compared with that of the bare ZnO or SnO$_2$. Though there have been a number of references reviewing the developments in the gas sensing performances of given metal oxides, only a few articles provide a comprehensive review of the effects of the heterojunctions on the enhanced gas sensing performances of composites based on nanostructured metal oxides or separately discuss heterojunctions with n-n, n-p, p-n or p-p structures. Moreover, the enhanced gas sensing mechanism of a given type of heterojunction to a reducing or an oxidising gas should also be studied and summarised. The synthesised methods and the gas sensing performances of the normally studied metal oxides as well as the important roles of the heterojunctions need to be systematically summarised and compared. This will allow us to fully understand the enhanced gas sensing properties of metal oxide heterojunctions.

In this review, the typical synthetic routes of n-n, n-p, p-n and p-p heterojunctions based on metal oxides are introduced. The gas sensing behaviours of the n-n/n-p heterojunctions (or p-n/p-p heterojunctions) are based on SnO$_2$ and TiO$_2$. ZnO, WO$_3$, MoO$_3$, In$_2$O$_3$, CuO, Cr$_2$O$_3$, NiO and Co$_3$O$_4$, etc., semiconductors are reviewed and compared to show the effects of the heterojunctions on the gas sensing performances of the metal oxides. The enhanced gas sensing mechanisms of the composites towards reducing and oxidising gases are also discussed in detail to systematically understand the role of the built heterojunctions in improving the gas sensing properties of the composites.

2. Nanostructured Metal Oxide Heterojunctions for High-Performance Gas Sensors

As reported, the formation of heterojunctions could be a positive effective strategy to improve the gas sensing performance of the metal oxides. Various methods such as hydrothermal [42], PLD [36], vapour-liquid-solid (VSL) [43], anodic oxidation [44], solvothermal treatment [45], sputtering [46], thermal evaporation [47], electrospinning [33], sol-gel [48] and spin-coating [49] have been successfully applied to assemble the heterostructures in the sensors, and are generally combined to form various heterojunctions (n-n, n-p, p-n or p-p types), as displayed in Figure 2. Other methods to assemble nanostructured metal oxide heterojunctions are listed in Tables S1–S4 (see Supporting Materials), along with the improved gas sensing performances of sensors based on n-p, n-n, p-n and p-p heterojunctions. Some of the typical nanostructured heterojunctions with the n-type (or p-type) metal oxides as the main phases are discussed in the following sections.

2.1. Enhanced Gas Sensing Performances of n-n Junctions or n-p Junctions

Heterojunctions with the n-p or the n-n structure in the sensing materials have been reported to be successful strategies to enhance their gas sensing properties. When the p-type metal oxide (acting as the second phase) is attached to an n-type metal oxide (acting as the main phase), an n-p heterojunction is formed between the two sensing metal oxides. Additionally, n-n heterojunctions can also be assembled in a similar way. One of the common routes to establish the n-n (or n-p) heterojunctions is to prepare the main n-type metal oxides and then decorate the prepared n-type metal oxides with the n-type (or p-type) metal oxides [50]. The modulation of the built potential barrier in the n-n or n-p heterojunction can effectively modify the resistance of the sensing material, and thus greatly improve the gas sensing properties of the sensor composed with the n-n (or
n-p) heterojunctions. Meanwhile, it is also noticed that the majority of heterojunctions are assembled as a decorated structure, core-shell structure or mixed structure (one metal oxide mixed with another metal oxide), discussed in the following subsections.

![Figure 2. Typical types of heterojunctions for high-performance gas sensors and assembly strategies.](image)

### 2.1.1. Gas Sensors Based on n-n Junctions

Many references report the improved gas sensing performances of sensors based on n-n heterojunctions. For example, Lu et al. reported the gas sensing properties of the ZnO-decorated SnO$_2$ hollow spheres towards the ethanol synthesised via a two-step hydrothermal method [39]. Hollow spheres of SnO$_2$ of ~100 nm thickness were synthesised via a facile template-free hydrothermal route (see Figure 3a,b) with ZnO nanoparticles of 10–30 nm diameter (see Figure 3c,d) uniformly decorated on its surface via a solution route. The sensor response of the ZnO-decorated SnO$_2$ hollow spheres was calculated to be 34.8 towards 30 ppm ethanol at their optimised operating temperature of 225 °C (see Figure 3e), much higher than that of the bare SnO$_2$ (~5.7 times). Their further research indicated that the composite also exhibited promising selectivity to acetone compared with methanol (Figure 3f). The recovery time of the composite towards 30 ppm ethanol (50 s) was also much shorter than that of acetone (120 s) at the same concentrations as shown in Figure 3g. In addition, the SnO$_2$ compositing with Co$_3$O$_4$ and SiO$_2$ have been reported to be promising gas sensing materials. The SnO$_2$/SiO$_2$ heterojunctions were synthesised via a facile method of a magnetron sputtering process and exhibited promising H$_2$ sensing performance at room temperature [51]. Hybrid Co$_3$O$_4$/SnO$_2$ core-shell nanospheres prepared with a one-step hydrothermal method demonstrated a measured response of 13.6 to 100 ppm NH$_3$ at 200 °C, a value two times higher than that of the solid nanospheres [52]. CeO$_2$-decorated ZnO nanosheets were prepared by a hydrothermal process in combination with the wet impregnation method, exhibited an enhanced sensor response of 90 to 100 ppm ethanol at 310 °C [53]. Additionally, Kim et al. have fabricated ZnO-SnO$_2$ nanofibres through an electrospinning process to effectively detect CO [54].
improved gas sensing performance to 10 ppm ethanol at 180 °C with a short response time of less than 40 s. Meanwhile, the SnO$_2$-core/ZnO-shell nanowires [56] and the Ga$_2$O$_3$-core/ZnO-shell nanorods [57] were successfully synthesised through a plasma-enhanced CVD and atomic layer deposition (ALD), respectively, which also exhibited promising gas sensing performances. The MoO$_3$ nanorods decorated with the ZnO nanoparticles were also reported to be a promising material to detect 100 ppm ethanol with a sensor response of ~30 at the working temperature of 250 °C [58]. Besides the nanocomposites discussed above, it was reported that α-MoO$_3$ compositing with WO$_3$ through a sol-gel method [59] or with Fe$_2$O$_3$ nanoparticles via a hydrothermal method [60] also showed improved gas sensing performances towards O$_2$ or xylene, respectively.

In addition, ZnO nanorods/TiO$_2$ nanoparticles [61] and the ZnO/La$_{0.8}$Sr$_{0.2}$Co$_{0.5}$Ni$_{0.5}$O$_3$ heterojunction structure [62] were successfully constructed to research their improved gas sensing performances to NO$_2$ and CO, respectively. WO$_3$ compositing with SnO$_2$ was reported to be a potential material to detect acetone [63], while WO$_3$-modified ZnO nanoplates synthesised via the hydrothermal route were assembled for the detection of...
NH₃ [26]. Other effective methods to synthesise n-n heterojunctions and their gas sensing performances are listed in Table S1.

2.1.2. Gas Sensors Based on n-p Junctions

The sensors based on the n-p heterojunctions have been found to show promising gas sensing properties towards various gases. For example, PdO nanoparticles-decorated flower-like ZnO structures (see Figure 4) were prepared by Zhang et al. through a surfactant-free hydrothermal process combined with a further heat treatment [42]. The Zn(AC)₂·2H₂O was used in the study to synthesise the flower-like ZnO structures, a certain amount of which was dissolved in a solution of NaOH, ethanol and deionized water. The obtained precursor was kept at 150 °C for 24 h. Before decorating with PdO nanoparticles, the flower-like ZnO structures were treated by an annealing process. The annealed ZnO nanoflowers were then dispersed in methanol solvent dissolving PdCl₂, and the collected products were calcined at 350 °C for 1 h to obtain the PdO-modified ZnO structures. The decorated flower-like ZnO was reported to show a gas sensor response of 35.4 to 100 ppm at 320 °C (see Figure 4e), which was much higher than that of the pure ZnO (~10 as shown in Figure 4f). Moreover, the composite presented a shorter recovery time of 7 s than that of the ZnO (14 s). ZnO/Co₃O₄ composite nanoparticles [64] and Al-doped ZnO/CuO nanocomposites [65] were reported to be sensitive to NO₂ and ammonia, respectively.

Gao et al. synthesised CuO nanoparticles-decorated MoO₃ nanorods through a hydrothermal process combined with an annealing process [66]. In the first step, MoO₃ nanorods were prepared with the raw material (NH₄)₆Mo₇O₂₄·4H₂O. Then, the obtained MoO₃ nanorods were dispersed in a solution of anhydrous ethanol and copper nitrate under high intensity ultrasonication. The final collected samples were annealed at 550 °C for 2 h. The CuO nanoparticles-decorated MoO₃ nanorods showed a higher H₂S sensor response of 272 at 270 °C compared with that of pure MoO₃, which was mainly attributed to the formation of n-p heterojunctions in the sensing material as reported in their article.
Nano-coaxial Co$_3$O$_4$/TiO$_2$ heterojunctions were successfully assembled through a typical two-step process by Yang et al. [44]. The authors firstly synthesised uniform TiO$_2$ nanotubular arrays via anodic oxidation of a Ti plate which were then decorated with Co$_3$O$_4$ nanoparticles by a hydrothermal process at 120 °C for 5 h. The sensor based on the nano-coaxial Co$_3$O$_4$/TiO$_2$ heterojunctions showed an enhanced sensor response of 40 to 100 ppm ethanol at 260 °C with a short response/recovery time of 1.4 s/7.2 s. The SnO$_2$-Co$_3$O$_4$ composite nanofibres were prepared through electrospinning combined with annealing with the working voltage of 15 kV [67]. The PdO nanoparticle-decorated WO$_3$ nanorods were also reported to be synthesised via a modified precipitation process combined with annealing at 300 °C for 2 h [68]. The SnO$_2$-Co$_3$O$_4$ composite nanofibres and the PdO nanoparticle-decorated WO$_3$ nanorods were found to be sensitive to 10 ppm C$_6$H$_6$ at 350 °C and 3.0 vol% of H$_2$ at 25 °C with enhanced sensor responses of 20 and 80.4, respectively.

CuO/ZnO heterostructural nanorods were prepared by Cao et al. via a combination of hydrothermal and wet-chemical processes [69]. The CuO nanoparticles-decorated ZnO nanorods array showed a sensor response of ~8 to 50 ppm towards triethylamine at a relatively low working temperature of 40 °C (higher than that of the bare ZnO nanorods of ~2.4), and a response time of 5 s (significantly shorter than that of the pure ZnO nanorods of ~11 s). Improved gas sensing performances were also observed in sensing materials composed of CuO-decorated SnO$_2$ nanowires [70]. CuO nanoparticles-decorated ZnO flowers [71], flower-like p-CuO/n-ZnO nanorods [72], NiO@ZnO heterostructured nanotubes [73], n-ZnO/p-NiO heterostructured nanofibres [74] and Co$_3$O$_4$ decorated flower-like SnO$_2$ nanorods [75]. The various methods used to assemble the n-p heterojunctions and their gas sensing properties are provided in Table S2.

Besides the nanocomposites discussed above, sensors based on the n-n or n-p heterojunctions have also been assembled to enhance the gas sensing performances of metal oxides. TiO$_2$ composited with ZnO, MoO$_2$, MoO$_3$, V$_2$O$_5$ and WO$_3$ have been designed and successfully established, exhibiting improved gas sensing performances towards ethanol, NO$_2$, alcohol and ammonia [33,55,76–78]. For example, the ZnO-decorated TiO$_2$ nanotube layer (prepared by anodic oxidation combined with atomic layer deposition) [76], TiO$_2$/V$_2$O$_5$ branched nanoheterostructures (synthesised by an electrospinning process followed by an annealing treatment) [33] and a TiO$_2$-WO$_3$ composite (obtained via plasma spraying technology using mixed feedstock suspensions) [77] have each exhibited promising gas sensing performances to 1170 ppm ethanol, 100 ppm ethanol and 100 ppm NO$_2$, respectively. α-Fe$_2$O$_3$ composited with SnO$_2$, In$_2$O$_3$ and CdO have also been successfully synthesised through hydrothermal, carbon sphere template and co-precipitating processes, enabling excellent gas sensitivity towards acetone, TMA and CO, respectively [37,79,80]. In$_2$O$_3$ composited with WO$_3$, Fe$_2$O$_3$ and TiO$_2$ and SnO$_2$ were also synthesised to assemble the high-performance gas sensors [81–84]. A series of In$_2$O$_3$-WO$_3$ nanofibres were prepared via an electrostatic spinning technology, which was reported to show an enhanced gas sensing performance to acetone with the n-n semiconductor heterojunctions formed at the interface between WO$_3$ and the In$_2$O$_3$ [81]. The sensor based on mixed Fe$_2$O$_3$-In$_2$O$_3$ nanotubes was also reported to show a high gas sensor response of 33 towards 100 ppm of formaldehyde at 250 °C [82]. TiO$_2$ nanoparticle-functionised In$_2$O$_3$ nanowires [83], SnO$_2$/In$_2$O$_3$ composite hetero-nanofibres [84], an octahedral-like ZnO/CuO composite [85] and a nanoporous SnO$_2$@TiO$_2$ heterostructure [86] were reported to show enhanced gas sensing properties towards acetone, formaldehyde and H$_2$S, respectively.

Based on the research discussed above, it is clear that the establishment of n-n or n-p heterojunctions can effectively improve the gas sensing properties of n-type metal oxides. Typically, n-type metal oxides are decorated with zero-dimensional nanoparticles and two-dimensional nanosheets, the concentrations of which have significant effects on the performance of the main n-type phase [67,87–89]. More specifically, the gas sensing performance of the main phase in a sensing material improves with increasing concentration of the second phase up to an optimal value, which can be attributed to the increase
in the specific surface area of the composite. However, the sensing property of the main phase always degenerates when the content of the second phase is further elevated. The interconnection of the second phase and decrease in the effective surface area was reported to be the two main factors causing a weakened sensor response of the composite. However, most of the reported sensors based on the n-n or n-p heterojunctions always worked at temperatures above 100 °C. We also found there are no clear strategies to indicate which material should be chosen to enhance the gas response of a certain n-type metal oxide, which may be paid more attention in the future by researchers.

2.2. Improved Gas Sensing Properties of p-n or p-p Junctions

Sensors based on the heterojunctions with p-n or p-p structures were also reported to exhibit promising gas sensing properties with high sensor responses and short response/recovery times. Similar to the formation of n-n or n-p heterojunctions, p-n and p-p junctions are also built with p-type metal oxides (as the main phase) decorated or coated with n-type or p-type metal oxides (as the second phase). The different Fermi levels of the metal oxides in the constructed p-n or p-p junctions induce the formation of a thick accumulation layer and thin depletion layer in the sensing composite. The modulation of the thickness of the accumulation layer (acting as the conductive channel of the carriers) significantly influences the conductivity of the sensors, further resulting in improved gas sensing properties of the p-n or p-p junctions.

2.2.1. Gas Sensors Based on p-n Junctions

The p-n heterojunctions in sensing materials have been reported to be effective in improving the gas sensing properties of metal oxides. For example, the SnO-SnO$_2$ composite (p-n heterojunction) was successfully prepared by a facile two-step method with the raw materials of SnCl$_2$·2H$_2$O, NaOH and CTAB at 140 °C for 5 h. Black SnO nanopowders were synthesised via a hydrothermal method at 140 °C for 5 h, and the obtained sample was then treated with an annealing process at a high temperature of 300–500 °C in air atmosphere to obtain the SnO–SnO$_2$ composite. The sensor response of the SnO-SnO$_2$ composite was 2.5 towards 200 ppm NO$_2$ at room temperature, significantly higher than that of pure SnO$_2$ (1.27) or bare SnO (1.1) [90]. The hydrothermal method was also applied to synthesise SnO$_2$-decorated NiO nanostructures (see Figure 5) with the raw sources of NiCl$_2$·6H$_2$O and SnCl$_4$·5H$_2$O at 160 °C for 12 h [91]. It is worth noting that NiO was modified with SnO$_2$ nanoparticles through a one-step process without any catalysts. The SnO$_2$-decorated NiO nanostructure was reported to show enhanced gas sensor responses to 1–200 ppm toluene (see Figure 5e,f). The calculated sensor response of the composite was measured to be 66.2 to 100 ppm toluene at 250 °C, more than 50 times higher than that of the pure NiO nanospheres (1.3). Moreover, the detection limit of this sensor was reported to be as low as 10 ppb toluene with a promising sensor response of 1.2.

Novel TiO$_2$-decorated Co$_3$O$_4$ acicular nanowire arrays were also successfully synthesised by Li et al. with a hydrogen thermal method combined with pulsed laser deposition. The acicular nanowire arrays modified with TiO$_2$ nanoparticles were found to present a high sensor response of 65 to 100 ppm ethanol at 160 °C, much higher than that of the pure Co$_3$O$_4$ nanowires (~25) [92]. In$_2$O$_3$-decorated CuO nanowires were also prepared through thermal oxidation of Cu meshes followed by the deposition of amorphous indium hydroxide from In(AC)$_3$ solution in ammonia [93]. The decorated CuO nanowires showed a shorter response time of 12 s to CO than that of the pure CuO nanowires (25 s). The novel rod-like α-Fe$_2$O$_3$/NiO heterojunction nanocomposites were synthesised with a one-step hydrothermal method, exhibiting an enhanced sensor response of 290 to 100 ppm acetone at 280 °C with a response time or a recovery time being 28 s or 40 s, respectively [94].
Figure 5. The XRD pattern (a) and the SEM images (b–d) of SnO$_2$ nanoparticles-modified NiO nanostructure (p-n junctions), the dynamic sensing performances of the pure NiO and the SnO$_2$ nanoparticles-modified NiO nanostructures towards 1–200 ppm toluene at 250 °C (c,e–h). Copied with permission [91]. Copyright 2018, Elsevier.

Additionally, CuO composited with TiO$_2$ [95] and SnO$_2$ [35] were constructed to investigate their improved gas-sensing properties. The nanofibres composed of SnO$_2$-CuO heterojunctions have been reported to be successfully synthesised by an electrospinning process and exhibited an improved sensor response of ~95 compared with that of the pure CuO (<10) [35]. Co$_3$O$_4$ composited with In$_2$O$_3$ [96], SiO$_2$ [97] and TiO$_2$ [98] were also successfully prepared via hydrothermal, thermal conversion and facile nanoscale coordination polymer routes, respectively, which showed better gas sensing properties than those of pure Co$_3$O$_4$. The reported sensors based on p-n heterojunctions and their gas sensing performances are listed in Table S3.

2.2.2. Gas Sensors Based on p-p Junctions

The p-p heterojunctions have been found to enhance the gas sensing performance of metal oxides. Li et al. prepared NiO@CuO nanocomposites (a p-p junction) via a facile reflux and hydrothermal process [99]. In their work, the Ni(OH)$_2$ was firstly synthesised with the raw material of nickel nitrate hexahydrate through a hydrothermal method at 140 °C for 5 h. Then, the obtained Ni(OH)$_2$ and the Cu(CH$_3$CO)$_2$·H$_2$O compounds were added in a solution separately with a certain amount of NaOH added during a reflux process to obtain the Ni(OH)$_2$@Cu$_2$(OH)$_3$NO$_3$. The synthesised products were finally treated by a calcination process in air atmosphere at 450 °C for 2 h. The prepared hierarchical flower-like nanostructured NiO-CuO composite exhibited an enhanced gas...
sensing performance to NO₂ at room temperature with a higher gas sensor response compared to pure NiO. The response time of the composite to the 100 ppm NO₂ was measured to be as low as 2 s, much shorter than that of the pure NiO. Moreover, the NiO/NiCr₂O₄ nanocomposite was also found to be more effective at detecting xylene than the pure NiO nanoparticles [100].

Co₃O₄ hollow nanocages (HNCs) decorated with PdO nanoparticles (see Figure 6a–d) were successfully assembled by the infiltration of metal precursors combined with a subsequent reduction process [101]. The gas sensing performance of the pure Co₃O₄ hollow nanocages was significantly improved when composites with PdO nanoparticles (PdO-Co₃O₄ HNCs), with the sensor response measured to be 2.51 towards 5 ppm acetone at 350 °C (see Figure 6e), which was higher than that of the Co₃O₄ powders (1.96), Co₃O₄ HNCs (1.45) or PdO-Co₃O₄ powders (1.98). Moreover, the PdO-Co₃O₄ HNCs also exhibited outstanding stability to 1 ppm acetone, which is shown in Figure 6f.

![Figure 6. SEM image (a), TEM image (b), HRTEM (c) and SEAD patterns (d) of the Co₃O₄ hollow nanocages (HNCs) decorated with PdO nanoparticles (p-p junctions), the dynamic sensing behaviours of the sensors based on Co₃O₄ powders, pure Co₃O₄ hollow nanocages, PdO-Co₃O₄ powders and PdO-Co₃O₄ HNCs towards 0.4–5 ppm acetone at 350 °C (e), the stability of the sensing performance of PdO-Co₃O₄ HNCs towards 1 ppm acetone (f). Lee et al. prepared TeO₂/CuO core-shell nanorods by a combined method of thermal evaporation and sputter deposition [102]. In the reported study, the Te powders were used as the raw material to synthesise TeO₂. The TeO₂ nanorods were prepared on a substrate of p-type Si (100) by thermal evaporation of Te powders at 400 °C in air in a quartz tube furnace. Then, a thin layer of CuO was directly sputtered on the surface of the obtained TeO₂ nanorods through a radio frequency magnetron sputtering process with a target of CuO. The sensor response of TeO₂-core/CuO-shell nanorods was found to be 4.25 to 10 ppm NO₂ at 150 °C, which was over two times higher than that of the pure TeO₂. However, the relatively low sensor response of the TeO₂/CuO core-shell nanorods is a
drawback that limits their application. Further studies are required to further improve the gas sensing performance of the TeO$_2$/CuO core-shell nanorods.

Meanwhile, p-NiFe$_2$O$_4$ nanoparticle-decorated p-NiO nanosheets were also synthesised with a solvothermal method [103]. The NiO precursor was firstly synthesised after which FeCl$_3$·6H$_2$O was added to prepare NiO nanosheets decorated with NiFe$_2$O$_4$ nanoparticles. The ratio of Fe/Ni was found to have a significant effect on the gas sensing performance of the decorated NiO nanosheets. The composite with the Fe/Ni-24.9 exhibited the optimal sensing performance to 50 ppm acetone at 280 °C, with a high response of ~23.0. The release of captured electrons back to the sensing material breaks the dynamic carrier balance between p-NiO and p-NiFe$_2$O$_4$. This resulted in a reduced potential barrier near the surfaces of the heterojunctions and yielded a large variation in resistance, improving the sensor response of the Fe/Ni-24.9 at%. The in situ formation of a second phase (p-NiFe$_2$O$_4$) on the first phase (p-NiO) was a novel and effective strategy to improve the interaction between the targeted gas and the sensing composite. Similar improvements in CuO-NiO nanotubes with controllable element content of Cu/N developed by a one-pot synthesis was also found, with a sensing capability towards 100 ppm glycol at 110 °C [104]. Based on the studies listed above, the in situ preparation of the second phase required further attention to improve the gas sensing performance of the sensor based on the metal oxide. Other sensors composed with p-p heterojunctions and their gas sensing performances are listed in Table S4.

Other types of heterojunctions based on metal oxides that improve gas sensing performances also exist. Duy et al. assembled n-p-n heterojunctions with the structure of SnO$_2$-carbon nanotube-SnO$_2$ by the method of CVD combined with spray coating process [105]. The obtained n-p-n heterojunctions showed a high response of 17.9 to 100 ppm NO$_2$ at 100 °C. The n-p-n heterostructure of the ZnO-branched SnO$_2$ nanowires decorated with Cr$_2$O$_3$ nanoparticles [106] or the p-n-p heterojunctions of PANI coated CuO-TiO$_2$ nanofibres [107] were also reported to exhibit improved gas sensing performance towards hydrogen and ammonia, respectively. However, only a few references report the study of the sensor based on n-p-n or p-n-p heterojunctions. More research should be conducted to systematically investigate the gas sensing properties of metal oxide heterojunctions comprising the n-p-n or the p-n-p structures.

Based on the discussions above, many kinds of metal oxides heterojunctions have been successfully assembled to enhance the gas sensing performance towards various gases. The sensor response of sensors based on heterojunctions was much higher than that of the pure metal oxides and the response time was improved. The n-n, n-p, p-n or p-p (even the n-p-n or p-n-p) heterojunctions can be chosen to be constructed to assemble gas sensors with outstanding properties. We should point out that the enhanced gas sensing mechanisms of certain heterojunctions towards the oxidising or reducing gases need to be clearly discussed and compared to fully understand the role of the heterojunctions. Therefore, in the next section, we review the mechanisms of the improvements in the gas-sensing properties of the metal oxide heterojunctions.

3. Enhanced Gas Sensing Mechanisms of the Metal Oxide Heterojunctions

Compared with the pure metal oxides, sensors based on metal oxide heterojunctions show improved gas sensing performances towards the targeted gases. When in contact with each other, the transfer of carriers between the two semiconductor materials is induced due to inconsistent Fermi levels at their interfaces. In the n-n or n-p heterojunctions, the Fermi levels of the two metal oxides will move up or down to an equilibrium state, resulting in the bending of their energy bands and the formation of a potential barrier between them [28]. The gas sensing performances of the studied metal oxides are reported to be mainly attributed to the redox reactions of the adsorbed targeted gases on the surfaces of the sensing materials, which has been widely reported by researchers to explain the gas sensing mechanisms of the assembled sensors [12,108]. The variation in the concentration of the carriers induced by the redox reactions on the surfaces of the composites could be
of importance to affect the height of the built-in potential barrier. This process further
influences the resistance or conductivity of the sensor based on n-n or n-p heterojunctions
according to Equation (1):

\[ \Delta R \propto \exp\left\{-e\Delta V_b/k_BT\right\} \]  

where the \( \Delta R \) is the change of the resistance of the sensor, \( \Delta V_b \) is the reduction of
the height of the potential barrier, \( k_B \) is the Boltzmann constant and \( T \) is the temperature [109].
Therefore, little change in the height of a potential barrier would make the resistance of
the investigated sensor vary greatly, leading to an improved gas sensing property of the
heterojunction [110]. In the case of the p-n or p-p heterojunctions, the interaction between
the targeted gases and the sensing materials would also modify the carriers (especially
holes) in the sensors, which would further result in the variation of the thickness of the
accumulating layer in the heterojunctions, making a more effective modulation in the
width of the conduction channel for the carriers. As a result, sensors based on p-n or p-p
heterojunctions also show improved gas sensing properties to the reducing or oxidising
gases [108]. Moreover, the composites composed of metal oxide heterojunctions always
show higher specific surface areas than the pure metal oxides, which was confirmed by BET
measurements of the composites. The higher specific surface area enables gas molecules to
diffuse more smoothly to the surface and more easily interact with the composite as well
as provide more active sites. The size of the pore volume can be increased with a higher
specific surface area, facilitating the diffusion of gas molecules into the sensing material and
increasing the active surface in internal parts of the composite for gas molecule adsorption.
The absorption and the desorption of the gas molecules can also be accelerated during the
response and recovery process of the sensor based on metal oxide heterojunctions.
Therefore, the high specific surface area forms another positive factor contributing to the
comprehensive improvements in the gas sensing performance of the composite [111–115].

Compared with the effect of the specific surface area, it is more complex to study the
enhanced gas sensing mechanisms of the heterojunctions in the sensing materials. The
role of the heterojunctions in enhanced gas sensing performances should be analysed in
detail to fully understand their direct and significant effects on the enhancement of the gas
sensing properties of the sensors based on the composites. In the following section, the gas
sensing mechanisms of the metal oxides to the common reducing and oxidising gases are
discussed, and the effects of various commonly studied heterojunctions on the improved
gas sensing properties of the composites are systematically investigated. In order to make
the discussions clear, \( \text{H}_2 \) (a typical reducing gas) and \( \text{NO}_2 \) (a typical oxidising gas) were
selected for the discussion of the enhanced gas sensing mechanisms of the metal oxides
due to their immense studies in the area of gas sensors.

3.1. Enhanced Gas Sensing Mechanisms to Reducing Gases

Gas sensors based on n-n or n-p heterojunctions always exhibit typical n-type sensing
performances at relatively low working temperatures towards reducing gases such as \( \text{H}_2 \),
\( \text{H}_2\text{S} \), \( \text{CO} \), \( \text{NH}_3 \) and ethanol. The widely studied ZnO-based material is taken as an example
to more clearly illustrate the sensing mechanism of the n-type metal oxide to a reducing
gas. The resistance of ZnO-based sensors has been reported to decrease quickly when \( \text{H}_2 \)
(ethanol or \( \text{H}_2\text{S} \)) is introduced onto their surface [116–118]. In air, oxygen molecules would
spontaneously be adsorbed on the active sites of the surface of the ZnO to form chemisorbed
oxygen molecules according to Equation (2). Then, the chemisorbed oxygen molecules
can capture electrons from the conductive bands of the ZnO to become the oxygen species
\( \text{O}^2^- \): \(<150\, ^\circ\text{C} \), \( \text{O}^- \): \(150\, ^\circ\text{C}–400\, ^\circ\text{C} \) and \( \text{O}_2^2^- \): \(>400\, ^\circ\text{C} \) based on Equation (3), which
builds a depletion layer in the ZnO surface and a high resistance in air. When \( \text{H}_2 \) gas
is introduced, the H\(_2\) molecules will interact with the pre-adsorbed oxygen species to
form \( \text{H}_2\text{O} \) based on Equation (4), releasing electrons back to ZnO. This response process
increases the concentration of electrons and decreases the thickness of the depletion layer in ZnO, leading to a decrease in the resistance of the sensor based on ZnO-based materials.

\[ O_2(g) + e^- \leftrightarrow O_2(ad) \]  \hspace{1cm} (2)

\[ O_2(ad) + e^- \leftrightarrow O_2^-(ad) \]  \hspace{1cm} (3)

\[ 2H_2(g) + O_2^-(ad) = 2H_2O(g) + e^- \]  \hspace{1cm} (4)

In contrast, composites made of p-n or p-p heterojunctions show typical p-type sensing performances towards reducing gases. As reported, the resistance of CuO nanowires increased when used to detect hydrogen gas (at working temperatures between 150 °C and 400 °C) [119]. When the CuO nanowires were placed in an air atmosphere, the oxygen molecule could also adsorb on the active sites in the surface of CuO to form adsorbed oxygen species (O\(^{-}\)) based on Equation (5), releasing holes to CuO and thus increasing the concentration of holes. This forms an accumulation layer in the sensing material, which acts as the conduction channel for carriers in CuO. In an H\(_2\) atmosphere, hydrogen molecules interact with the adsorbed oxygen molecules according to Equation (6), reducing the concentration of carriers and the thickness of the accumulation layer and induces the formation of a depletion layer on the surface of CuO. Therefore, the resistance of a sensor based on CuO nanowires increases in reducing gas environments [108,119].

\[ O_2(g) \leftrightarrow O_2^-(ad) + h^+ \leftrightarrow 2O^-(ad) + 2h^+ \]  \hspace{1cm} (5)

\[ 2H_2(g) + 2O^-(ad) + 2h^+ = 2H_2O(g) \]  \hspace{1cm} (6)

The synthesis of TiO\(_2\) nanotubes decorated with SnO\(_2\) nanoparticles and their H\(_2\) sensing performance has been reported [89] and is selected to analyse the important role of the typical n-n heterojunction in improving the sensing performance of the sensor towards reducing gases. The results showed that the H\(_2\) sensing property of the TiO\(_2\)-based composite was highly improved with the help of the heterojunction between TiO\(_2\) and SnO\(_2\). It was reported that the Fermi level of TiO\(_2\) was higher than that of SnO\(_2\), resulting in the electron transfer to SnO\(_2\) from TiO\(_2\) until achieving the equilibrium states of their Fermi levels. This would make a thick depletion layer formed at the interface between TiO\(_2\) and SnO\(_2\) and induce a high potential barrier built in air due to the adsorption of oxygen molecules. The potential barrier always acts as the obstacle to the transportation of electrons in the sensing materials, resulting in the high resistance of the composites. The accumulation of electrons in the SnO\(_2\) side would induce more oxygen molecules adsorbed onto the surface of the composite. When hydrogen gas is introduced, the hydrogen gas interacts with the adsorbed oxygen species on the surfaces of TiO\(_2\) and SnO\(_2\) immediately and releases electrons back to the sensing materials. The released electrons would decrease the thickness of the depletion layers between TiO\(_2\) and SnO\(_2\), further resulting in the decrease in the height of the potential barrier. This process would increase the conductivity of the sensor and significantly enhance the H\(_2\) sensing performance of the composite. The porous MoO\(_3\)/SnO\(_2\) nanoflakes with n-n junctions was also reported to show an improved gas sensing property with a higher gas sensor response being 43.5 towards 10 ppm H\(_2\)S at 115 °C compared with that of the pure SnO\(_2\), which could also be attributed to the reasons mentioned previously (see Figure 7a1,a2) [120]. Moreover, the improvement in the H\(_2\)S or xylene sensing performance of TiO\(_2\)-decorated α-Fe\(_2\)O\(_3\) nanorods [121] or Fe\(_2\)O\(_3\) nanoparticles-decorated MoO\(_3\) nanobelts [122] could also be explained by the enhanced gas sensing mechanism above.
the decrease in the height of the potential barrier. This process would increase the conductivity of the sensor and significantly enhance the H2 sensing performance of the composite. The porous MoO3/SnO2 nanoflakes with n-n junctions was also reported to show an improved gas sensing property with a higher gas sensor response being 43.5 towards 10 ppm H2S at 115 °C compared with that of the pure SnO2, which could also be attributed to the reasons mentioned previously (see Figure 7a1,a2) [120]. Moreover, the improvement in the H2S or xylene sensing performance of TiO2-decorated \( \alpha \)-Fe2O3 nanorods [121] or Fe2O3 nanoparticles-decorated MoO3 nanobelts [122] could also be explained by the enhanced gas sensing mechanism above.

**Figure 7.** The enhanced gas sensing mechanisms of (a1,a2) MoO3/SnO2 nanoflakes (n-n heterojunction) (Copied with permission [120]. Copyright 2019, American Chemical Society), (b1,b2) NiO-Nb2O5 composite nanoparticles (n-p heterojunction) (Copied with permission [123]. Copyright 2017, Elsevier) and (c1,c2) Nb2O5 nanoparticle-decorated CuO nanorods (p-n heterojunction) (Copied with permission [119]. Copyright 2017, Springer Nature) to reducing gases.

In the case of sensors based on n-p heterojunctions, the NiO-decorated Nb2O5 nanocomposites have been reported to exhibit a significant improvement in the H2 gas sensing performance compared with that of the pure Nb2O5 nanoparticles [123]. When the NiO nanoparticles are loaded onto the surface of the Nb2O5 nanoparticles, the electrons diffuse to the Nb2O5 and the holes move toward the NiO, causing the Fermi levels of the two different metal oxides to reach an equilibrium state. In air, the adsorption of the oxygen molecules on the surfaces of the NiO and the Nb2O5 also results in the formation of an accumulation layer of holes in the NiO side and a depletion layer in the Nb2O5 side. This causes the energy bands of NiO to bend upwards, increasing the potential barrier at the
with the introduced gas molecules, capturing the holes from CuO and NiO. This process induces the formation of a depletion layer between NiO and Nb$_2$O$_5$ and makes the energy bands of NiO bend downwards, dramatically decreasing the height of the potential barrier at the heterojunction (see Figure 7b1,b2). The NiO nanoparticles have also been reported to be an excellent catalyst to effectively oxidise H$_2$, causing reactions between the adsorbed H$_2$ and the adsorbed oxygen species to occur more sufficiently and smoothly. As a result, the NiO-decorated Nb$_2$O$_5$ nanocomposites exhibit an improved gas sensing property to H$_2$. The enhanced gas sensing performances of the Co$_3$O$_4$-decorated WO$_3$ nanowires [124], SnO$_2$-Co$_3$O$_4$ composite nanofibres [67], CuO-loaded In$_2$O$_3$ nanofibres [125], hierarchical SnO/SnO$_2$ nanocomposites [126], ZnO nanowire arrays/CuO nanospheres heterostructures [127] and p-NiS/n-In$_2$O$_3$ heterojunction nanocomposites [34] towards reducing gases can also be attributed to the reasons listed above.

For the p-n junction, Lee et al. reported the sensor based on Nb$_2$O$_5$ nanoparticles-decorated CuO nanorods to be more sensitive towards hydrogen molecules than the pure CuO nanorods [119]. The higher Fermi level of Nb$_2$O$_5$ makes the electrons diffuse to the CuO and the holes transfer in an opposite orientation, leading to the bending of energy bands. In air, the adsorption of oxygen molecules captures the electrons from Nb$_2$O$_5$ but releases the holes to the CuO, resulting in the formation of a thick depletion layer in Nb$_2$O$_5$ and a thick accumulation layer in the CuO. This leads to the high potential barrier in the composite in air. As reported, the accumulation layer in the CuO can act as a conduction channel for carriers in the sensing material. When exposed to H$_2$, the hydrogen molecule can interact with the adsorbed oxygen species on the Nb$_2$O$_5$ and the CuO, releasing the electrons back to the Nb$_2$O$_5$ but capturing the holes in the CuO. Effectively, this decreases the thickness of the depletion layer in Nb$_2$O$_5$ and significantly thins the accumulation layer in CuO with the possible formation of a depletion layer in the CuO, attributed to more oxygen molecules adsorbed on the surface of the CuO due to the formation of heterojunctions. This dramatic decrease in the thickness of the accumulation layer greatly narrows the conduction channel width for carriers, as shown Figure 7(c1,c2). As a result, the Nb$_2$O$_5$ nanoparticle-decorated CuO nanorods exhibited an improved p-type sensing performance to H$_2$. The improved sensing mechanism could also reasonably explain the enhancements in the gas sensing performances of the In$_2$O$_3$-decorated CuO nanowires [93], SnO$_2$-decorated NiO nanostructure [91], hierarchical α-Fe$_2$O$_3$/NiO composites [128], SnO$_2$-decorated NiO foam [129] and Cu$_x$O-modified ZnO composite [130] with a hollow structure towards H$_2$, the toluene and the acetone.

Similarly, in the case of the p-p heterojunction, p-NiO-decorated p-CuO microspheres were prepared through a hydrothermal process and studied the enhanced gas sensing performance of the obtained composite with p-p heterojunctions [131]. The Fermi level of the CuO was higher than that of the NiO, resulting in the transfer of holes from NiO to CuO and the diffusion of electrons to NiO from CuO. As such, accumulation and depletion layers of holes build on the CuO and the NiO sides, respectively. In air atmosphere, the adsorption of the oxygen molecules on the surfaces of CuO and NiO releases holes to the sensing material as previously mentioned. As a result, the thickness of the depletion layer of the holes in NiO decreases, but the thickness of the accumulation layer of the holes in the CuO increases. The width of the conduction channel increased in the heterojunctions between CuO and NiO, causing a low resistance of the composite. When a reducing gas was introduced on the surface of the composite, the adsorbed oxygen ions reacted with the introduced gas molecules, capturing the holes from CuO and NiO. This process decreases the concentration of the carriers in the sensing materials, further increasing the thickness of the depletion layer of the holes in NiO and decreasing the thickness of the accumulation layer of holes in CuO. Therefore, the width of the conduction channel increased in the heterojunctions was significantly narrowed, causing an increase in the resistance of the composites. Therefore, the gas sensor response of the p-NiO-decorated
p-CuO microspheres was highly improved towards reducing gases. The enhanced gas sensing mechanisms of p-NiO/p-NiCr$_2$O$_4$ nanocomposites [132] or the Cr$_2$O$_3$-Co$_3$O$_4$ nanofibres [133] to xylene or C$_2$H$_5$OH can also be explained by the above discussions.

Apart from H$_2$, there are also a number of references reporting similar improved sensing mechanisms of sensors based on metal oxide heterojunctions towards NH$_3$, another widely investigated reducing gas. The work conducted by Shi et al. showed that the sensor response of WO$_3$@CoWO$_3$ (n-n type) heterojunction nanofibres was over 10 times higher than that of the bare WO$_3$ at room temperature [134]. The authors pointed out the formation of a number of heterojunctions for WO$_3$ compositied with CoWO$_3$ in the sensing material. The differences in the Fermi levels of WO$_3$ and CoWO$_3$ cause band bending and trigger the transfer of electrons and holes between them until an equilibrium in final Fermi levels is reached. In air, oxygen gas can be adsorbed on the surface of the two different sensing materials and capture electrons from their conductive bands to form chemisorbed oxygen ions (O$_2^-$ at room temperature) according to Equation (3). This process results in a wider depletion layer and constructs a higher potential barrier near the surface of the heterojunction in the composite than those in the pure CoWO$_3$. NH$_3$ molecules could interact with the O$_2^-$ according to the following equation: $4\text{NH}_3(ad) + \text{O}_2^-(ad) \rightarrow 4\text{NO}(g) + 6\text{H}_2\text{O}(g) + 5e^-$. Electrons were then released back to the sensing materials of the WO$_3$@CoWO$_3$ composite, reducing the thickness of the depletion layer and decreasing the height of the potential barrier at the heterojunction. As a result, the sensing performance of WO$_3$@CoWO$_3$ heterojunction nanofibres towards NH$_3$ could be significantly enhanced at room temperature. Additionally, the specific surface area of the composite was higher, allowing more electrons to be transferred from the shallow donor levels of the WO$_3$ nanoparticles to CoWO$_3$ nanoparticles in the composite, thus enabling the enhanced NH$_3$ sensing property of the sensor based on the metal oxide heterojunction. The study of Gong et al. also revealed that the enhanced NH$_3$ sensing performance of the flower-like n-ZnO decorated with p-NiO with hierarchical structure was mainly attributed to the formation of the depletion layer and the modulation of the potential barrier height at the surface of the heterojunction [135]. A similar improved sensing mechanism was also reported in the enhanced NH$_3$ sensing performance of the sensors based on other heterojunctions, including polyaniline/SrGe$_2$O$_9$ nanocomposite [136], polyaniline nanograin enchased TiO$_2$ fibres [137], SnO$_2$@polyaniline nanocomposites [138], V$_2$O$_5$/CuWO$_3$ heterojunctions [139], Fe$_2$O$_3$-ZnO nanocomposites [49], rGO/WO$_3$ nanowire nanocomposites [140], WO$_3$@SnO$_2$ core-shell nanosheets [141], PANI-Co$_2$O$_3$ nanocomposite thin films [142], CuPc-loaded ZnO nanorods [143], Co$_3$O$_4$ nanorod-decorated MoS$_2$ nanosheets [144], SnO$_2$/NiO composite nanowebss [145], bilayer SnO$_2$-WO$_3$ nanofilms [146], Cu$_2$O nanoparticles decorated with p-type Mo$_2$S nanosheets [147], TiO$_x$ and NiO nanostructured bilayer thin films [148] and mesoporous In$_2$O$_3$@CuO multijunction nanofibres [149].

3.2. Improved Gas Sensing Mechanism towards Oxidising Gases

In contrast to the sensing behaviour of n-n or n-p heterojunctions towards reducing gases, sensors based on n-n or the n-p heterojunctions were reported to exhibit a typical p-type sensing performance towards the oxidising gases. Many researchers have studied the oxidising gas (such as NO$_2$) sensing performance of heterojunctions based on n-type metal oxides at working temperatures within the range of 150 °C to 400 °C. The ZnO nanoparticles exhibited a typical p-type sensing performance towards 0.3–10 ppm NO$_2$ at the working temperature of 250 °C, with the resistance of the sensor increasing quickly when exposed to an NO$_2$ gas atmosphere [150]. In air, oxygen molecules can adsorb onto the active sites of the surface of the nanostructured ZnO according to Equation (7), capturing electrons from the conductive bands of ZnO. This process causes a decrease in carriers in ZnO and the formation of a depletion layer on the surface of ZnO. When exposed to an NO$_2$ atmosphere, the NO$_2$ molecules can interact with the ZnO directly and with adsorbed O$^-$ on the ZnO according to Equations (8) and (9), respectively. Generally, NO$_2$ can be adsorbed onto the active sites of the ZnO surface based on Equation (8),
capturing the electrons from the ZnO to form NO$_2^-$.

The NO$_2^-$ can then further react with adsorbed oxygen species following Equation (9), grabbing electrons from ZnO. These sensing processes decrease the concentration of the carriers in the ZnO and increase the thickness of the depletion layer in the surface of the ZnO, resulting in a significant increase in the resistance of ZnO and the p-type sensing performance to NO$_2$ gas.

$$\frac{1}{2}O_2(g) + e^{-} \leftrightarrow O^-(ad)$$  \hspace{1cm} (7)

$$NO_2(g) + e^{-} \leftrightarrow NO_2^-(ad)$$  \hspace{1cm} (8)

$$NO_2^-(ad) + O^-(ad) + 2e^- \leftrightarrow NO(g) + 2O_2^-$$  \hspace{1cm} (9)

In addition, sensors based on p-n or p-p heterojunctions have been found to show typical n-type sensing performances towards oxidising gases. The resistances of the sensors assembled by heterojunctions based on p-type metal oxides decrease rapidly when exposed to oxidising gases at the working temperatures of approximately 200 °C. Taking the sensor based on Co$_3$O$_4$ as an example, oxygen molecules can be adsorbed onto the active sites on the surface of Co$_3$O$_4$ according to Equation (5), releasing holes to Co$_3$O$_4$ and resulting in the formation of chemisorbed oxygen species (mainly O$^-$). This process can also induce the establishment of an accumulation layer in the surface of Co$_3$O$_4$. In an NO$_2$ atmosphere, NO$_2$ molecules have also been reported to adsorb onto the active sites of a Co$_3$O$_4$ surface based on Equation (10), releasing holes to the sensing materials and forming NO$_2^-$. The adsorbed NO$_2^-$ can then interact with the adsorbed oxygen species according to Equation (11), releasing more holes to Co$_3$O$_4$. These processes make the accumulating layer thicker on the surface of Co$_3$O$_4$ and cause the resistance of the sensor to decrease, leading to an n-type sensing performance of the Co$_3$O$_4$-based sensor towards NO$_2$ [64].

$$NO_2(g) \leftrightarrow NO_2^-(ad) + h^+$$  \hspace{1cm} (10)

$$NO_2^-(ad) + O^-(ad) \leftrightarrow NO(g) + 2O_2^-(ad) + 2h^+$$  \hspace{1cm} (11)

For the sensor based on an n-n heterojunction, the study of the gas sensing properties of ZnO-SnO$_2$ hollow nanofibres showed that the composites exhibit a much higher sensor response towards NO$_2$ than pure SnO$_2$ [15]. In the composite, the Fermi level of the SnO$_2$ is higher than that of the ZnO. The lower Fermi level of the ZnO can thus lead to the transfer of the holes from ZnO to SnO$_2$ and the diffusion of electrons to ZnO from SnO$_2$ until their Fermi levels reach an equilibrium state. This process can then form a thick accumulation layer on the ZnO side and a thin depletion layer on the SnO$_2$ side. In air atmosphere, oxygen molecules can adsorb onto the surface of SnO$_2$, which would capture electrons from SnO$_2$ and increase the thickness of the built-in depletion layer. The accumulation layer of the electrons in ZnO can cause more molecules to absorb onto its surface in air, capturing electrons and significantly decreasing the thickness of the established accumulation layer and even lead to the formation of a thin depletion layer (see Figure 8(a1)). In an NO$_2$ atmosphere, adsorbed NO$_2$ molecules on the surfaces of the metal oxides and the reaction between NO$_2$ and adsorbed oxygen molecules further capture electrons in ZnO and SnO$_2$, significantly increase in the depletion layer at the interfaces between ZnO and SnO$_2$ (see Figure 8(a2)). As a result, the height of the potential barrier increases greatly, making the ZnO-SnO$_2$ hollow nanofibres exhibit an improved NO$_2$ gas sensing property. The sensors based on ZnO nanorods decorated with TiO$_2$ nanoparticles [61], Bi$_2$O$_3$-branched SnO$_2$ nanowires [112], In$_2$O$_3$-composited SnO$_2$ nanorods [152] and SnO$_2$-core/ZnO-shell nanowires [153] also exhibited improved NO$_2$ gas sensing performances according to the mechanism discussed above.
greatly, making the ZnO-SnO$_2$ hollow nanofibres exhibit an improved NO$_2$ gas sensing property. The sensors based on ZnO nanorods decorated with TiO$_2$ nanoparticles \cite{61}, Bi$_2$O$_3$-branched SnO$_2$ nanowires \cite{112}, In$_2$O$_3$-composited SnO$_2$ nanorods \cite{152} and SnO$_2$-core/ZnO-shell nanowires \cite{153} also exhibited improved NO$_2$ gas sensing performances according to the mechanism discussed above.

Figure 8. The enhanced gas sensing mechanisms of (a1,a2) the hollow nanofibres of ZnO-SnO$_2$ (n-n heterojunction) (Copied with permission \cite{151}. Copyright 2018, Elsevier.), (b1,b2) the ZnO/Co$_3$O$_4$ composite nanoparticle (n-p heterojunction) (Copied with permission \cite{64}. Copyright 2016, Elsevier.) and (c1,c2) NiO-SnO$_2$ nanocomposites (p-n heterojunction) (Copied with permission \cite{154}. Copyright 2016, Royal Society of Chemistry.) towards oxidising gases.

In the case of the n-p junction, Co$_3$O$_4$-decorated ZnO nanoparticles have been established by Lee et al. and showed a significant enhancement in the NO$_2$ gas sensing performance \cite{64}. The Fermi level of ZnO is higher than that of Co$_3$O$_4$, inducing the transfer of carriers between them and the formation of a depletion layer at the heterojunction. In air, the adsorption of the oxygen molecules on the surfaces of ZnO and Co$_3$O$_4$ capture the electrons from ZnO and release holes to Co$_3$O$_4$. This leads to the building of a depletion layer on the ZnO side and an accumulation layer on the Co$_3$O$_4$ side as well as a significant bending in their energy bands (see Figure 8(b1)). As a result, a potential barrier is formed...
at the interfaces between ZnO and Co$_3$O$_4$, resulting in a higher resistance of the sensor based on the composites than that of pure ZnO. In an NO$_2$ atmosphere, the adsorption of NO$_2$ molecules on the surfaces of ZnO and Co$_3$O$_4$ can lead to the capture of electrons from ZnO but the release of the holes to Co$_3$O$_4$. The variation in the carriers in ZnO and Co$_3$O$_4$ causes both the depletion layer in ZnO and the accumulation layer in Co$_3$O$_4$ to become thicker. This sensing process increases the height of the potential barrier in the heterojunctions and significantly increases the resistance of the Co$_3$O$_4$-decorated ZnO composite (see Figure 8(b1,b2)). Meanwhile, the catalytic property of Co$_3$O$_4$ to NO$_2$ also acts as a positive factor for the improved NO$_2$ gas sensing performance of the composite. Oxygen molecules are reported to be more easily adsorbed onto the surface of p-type metal oxides, which is another reason for the improved NO$_2$ gas sensing performance of the Co$_3$O$_4$-decorated ZnO nanoparticles. The improvements in the NO$_2$ gas sensing properties of the SnO-SnO$_2$ nanocomposites [90], CuO-decorated ZnO nanowires [155], TeO$_2$/SnO$_2$ brush-nanowires [156] and ultra-long ZnO@Bi$_2$O$_3$ heterojunction nanorods [157] can also be attributed to the reasons listed above.

Sensors based on the p-n heterojunctions have also been reported to be effective at detecting oxidising gases. For example, NiO-SnO$_2$ nanocomposites (p-n junctions) were found to exhibit an improved gas sensing performance towards NO$_2$ compared with pure NiO [154]. The Fermi level of the n-type SnO$_2$ was found to be higher than that of the p-type NiO. The electrons would be transferred from SnO$_2$ to the NiO, and the holes would diffuse from the NiO to the SnO$_2$. In an air atmosphere, the adsorption of oxygen molecules would capture electrons in the SnO$_2$ and release the holes to NiO, resulting in the formation of a thin depletion layer in SnO$_2$ and an accumulation layer in NiO. A potential barrier is then established between NiO and SnO$_2$, and the carriers in the sensing materials are mainly transported through the accumulation layer. In an NO$_2$ atmosphere, the adsorption of NO$_2$ molecules on the surface of NiO results in more holes being released to NiO, further increasing the thickness of the accumulation layer in the NiO layer. The adsorption of NO$_2$ molecules on the surface of SnO$_2$ would allow more electrons to be grabbed from the SnO$_2$, further increasing the thickness of the depletion layer in SnO$_2$. Moreover, NO$_2$ can be adsorbed on SnO$_2$ more easily due to its higher electron concentration. There would be more NO$_2$ molecules adsorbed on the NiO-SnO$_2$ nanocomposites, further resulting in the great modulation in the accumulation layer of the heterojunction nanocomposites. The increase in the thickness of the accumulation layer in NiO would widen the conduction channel for the carriers, which would result in a significant decrease in the resistance of the sensing material (see Figure 8(c1,c2)). Therefore, the sensors based on NiO-SnO$_2$ nanocomposites exhibit a higher sensor response to NO$_2$ than that of bare NiO.

For the p-p heterojunction, the NO$_2$ gas sensing performance of sensors based on p-type NiO nanosheets could be successfully improved through modifying them with the p-type CuO nanoparticles [158]. In the CuO-decorated NiO nanosheets, the differences in Fermi levels of CuO and NiO lead to the transfer of carriers between the two, resulting in the formation of a hole depletion layer and a hole accumulation layer between their interfaces. In air, the adsorption of oxygen molecules on the surfaces of CuO and NiO can release holes to the sensing materials, leading to the increase in the thickness of the accumulation layer at the interfaces between CuO and NiO. When NO$_2$ is introduced and interacts with the sensing material, more holes are released to CuO and NiO. Moreover, more NO$_2$ molecules become adsorbed on the sensing material due to the accumulation of holes in the composite and its higher specific surface area. This sensing process would more effectively increase the carriers (holes) in the composites and widen the accumulation layer between CuO and NiO. As a result, the resistance of the p-p heterojunctions significantly decreased and the CuO-decorated NiO nanosheets presented an enhanced NO$_2$ gas sensing performance. The enhanced NO$_2$ sensing mechanism discussed above can also be applied to explain the improved NO$_2$ sensing properties of the sensors based on CuO-decorated TeO$_2$ nanorods [102] and vertically aligned Cu$_3$Mo$_2$O$_9$ micro/nanorods on a CuO layer (Cu$_3$Mo$_2$O$_9$@CuO nanorods) [159].
The discussions of the enhanced gas sensing mechanisms of the n-n, n-p, p-n and p-p heterojunctions reveal that modulations of the height of the potential barriers and the thickness of the accumulation layer in the heterojunctions are responsible for the improvements of the gas sensing performances of the nanocomposites. The different Fermi levels of the metal oxides induce band bending in the heterojunctions, leading to the formation of potential barriers and accumulation layers in n-type and p-type heterojunctions, respectively. The interactions between the targeted gases and the sensing materials cause variations in the height of the potential barriers in n-type heterojunctions (n-n or n-p heterojunctions) and the thickness of the accumulation layer in p-type heterojunctions (p-n or p-p heterojunctions), inducing enhancements of the sensing performance of the composites.

4. Conclusions

The gas sensing performances of metal oxides have been successfully improved through assembling heterojunctions in sensing materials. The heterojunctions are usually constructed via combined methods of electrospinning, thermal oxidation, ALD, PLD, hydrothermal process and CVD. The sensor response, response time or recovery time based on n-n, n-p, p-n or p-p heterojunctions can be effectively enhanced. Modulations in the built-in heterojunctions are mainly responsible for the enhanced gas sensing performances of the sensors based on n-n or n-p junctions. The improvement in the gas sensing behaviours of the sensors based on p-n or p-p heterojunctions can be attributed to variations in the thicknesses of the accumulation layers in the junctions. n-type or p-type nanostructured metal oxides with different morphologies can be selected to assemble heterojunctions and their concentrations can modified, indicating that more interesting gas sensors based on nanostructured metal oxide heterojunctions might be explored.
