A Corrigendum on

Distribution and Diversity of Comammox *Nitrospira* in Coastal Wetlands of China

Sun, D., Tang, X., Zhao, M., Zhang, Z., Hou, L., Liu, M., et al. (2020). Front. Microbiol. 11:589268. doi: 10.3389/fmicb.2020.589268

In the original article, there was a mistake in Figure 1, Location of sampling sites in the estuarine tidal flat wetlands of China. as published. There was a mistake in the scale label. The corrected Figure 1 appears below.

In the original article, there was a mistake in Figure 4, (A) Abundance of ammonia-oxidizers in the distinct areas based on qPCR results. as published. There was a mistake in the values on the Y-axis. The corrected Figure 4 appears below.

In the original article, there was a mistake in Figure 5, Network analysis of all ammonia oxidizers. Different colored circles represent different ammonia oxidants, orange lines represent negative interaction, black lines represent positive interaction. as published. The colors indicating negative and positive interactions were not clearly shown. The corrected Figure 5 appears below.

In the original article, there was a mistake in Table 1, Distribution of ammonia-oxidizers in different ecosystems. as published. The values and units were not correctly indicated in the Table. The corrected Table 1 appears below.

In the original article, there was an error. There were some errors in the values of copy numbers. A correction has been made to the Abstract:

Complete ammonia oxidizers (comammox), able to individually oxidize ammonia to nitrate, are considered to play a significant role in the global nitrogen cycle. However, the distribution of comammox *Nitrospira* in estuarine tidal flat wetland and the environmental drivers affecting their abundance and diversity remain unknown. Here, we present a large-scale investigation on the geographical distribution of comammox *Nitrospira* along the estuarine tidal flat wetlands of China, where comammox *Nitrospira* were successfully detected in 9 of the 16 sampling sites. The abundance of comammox *Nitrospira* ranged from 4.15 × 10⁵ to 6.67 × 10⁶ copies/g, 2.21- to 5.44-folds lower than canonical ammonia oxidizers: ammonia-oxidizing bacteria (AOB) and ammonia-oxidizing archaea (AOA). Phylogenetic analysis based on the alpha subunit of the
ammonia monoxygenase encoding gene (amoA) revealed that comammox *Nitrospira* Clade A, mainly originating from upstream river inputs, accounts for more than 80% of the detected comammox *Nitrospira*, whereas comammox *Nitrospira* clade B were rarely detected. Comammox *Nitrospira* abundance and dominant comammox *Nitrospira* OTUs varied within the estuarine samples, showing a geographical pattern. Salinity and pH were the most important environmental drivers affecting the distribution of comammox *Nitrospira* in estuarine tidal flat wetlands. The abundance of comammox *Nitrospira* was further negatively correlated with high ammonia and nitrite concentrations. Altogether, this study revealed the existence, abundance and distribution of comammox *Nitrospira* and the driving environmental factors in estuarine ecosystems, thus providing insights into the ecological niches of this recently discovered nitrifying consortium and their contributions to nitrification in global estuarine environments.

In the original article, there was an error. There were some errors in the values of copy numbers.

A correction has been made to RESULTS, Abundance of Comammox *Nitrospira* and Canonical Ammonia Oxidizers, Paragraph 2:

Among the canonical ammonia oxidizers, which were detected in all samples, abundance ranged from $1.15 \times 10^6$ to $3.66 \times 10^7$ copies/g dry soil (AOA) and $1.76 \times 10^5$ to $1.73 \times 10^7$ copies/g dry soil (AOB) (Supplementary Figure 3). In 10 of the 16 estuarine tidal flat wetland samples AOA showed higher abundance than AOB (Supplementary Figure 4). The abundance of AOA was positively correlated with temperature ($r = 0.44$, $p < 0.01$, $n = 48$) with highest abundance in estuaries of central and southern latitudes. Contrary, AOB were mainly distributed across the central and northern latitudes, and dominated ammonia oxidizer abundances at the northern latitudes.

In the original article, there was an error. There were some errors in the values of copy numbers.

A correction has been made to DISCUSSION, Distribution of Comammox *Nitrospira* in Estuarine Tidal Flat Wetlands of China, Paragraph 1:

Comammox *Nitrospira* were detected from 9 of the 16 sampling sites. The abundance of comammox *Nitrospira* ranged from $4.15 \times 10^5$ to $6.66 \times 10^6$ copies/g, 2.21- to 5.44-folds lower than canonical ammonia oxidizers: AOA and AOB, which were both detected at every sampling location. The three types of microorganisms use ammonia as an energy substance, and hence are in direct nutrient competition. However, they are able to coexist in most environments. In the estuarine tidal flat wetlands nitrifying microbial network (AOA, AOB, and comammox *Nitrospira*) (Figure 5), the correlation between all species is mainly positive (98.17%) and their abundance is equally correlated with the detected PNRs. The average ratio of comammox *Nitrospira* to AOA and AOB is 0.18 and 0.46. From the proportion of abundance, the contribution of comammox *Nitrospira* to the PNRs and hence nitrification may be smaller than that of AOA and AOB. The abundance of AOA was higher than that of AOB in 10 of the 16 sediment

samples, with the AOA/AOB ratio ranging from 0.22 up to 205. No significant decreases of PNRs could be observed in intertidal sediment after AOB were inhibited by ampicillin, implying that AOA might play the most important role for the nitrification potential in this specific ecosystem (Zheng et al., 2014).
