Abstract

The notion of generalized rank invariant in the context of multiparameter persistence has become an important ingredient for defining interesting homological structures such as generalized persistence diagrams. Naturally, computing these rank invariants efficiently is a prelude to computing any of these derived structures efficiently. We show that the generalized rank over a finite interval $I$ of a $\mathbb{Z}^2$-indexed persistence module $M$ is equal to the generalized rank of the zigzag module that is induced on a certain path in $I$ tracing mostly its boundary. Hence, we can compute the generalized rank over $I$ by computing the barcode of the zigzag module obtained by restricting the bifiltration inducing $M$ to that path. If the bifiltration and $I$ have at most $t$ simplices and points respectively, this computation takes $O(t^\omega)$ time where $\omega \in [2, 2.373)$ is the exponent of matrix multiplication.

Among others, we apply this result to obtain an improved algorithm for the following problem. Given a bifiltration inducing a module $M$, determine whether $M$ is interval decomposable and, if so, compute all intervals supporting its summands.

1 Introduction

In Topological Data Analysis (TDA) one of the central tasks is that of decomposing persistence modules into direct sums of indecomposables. In the case of a persistence module $M$ over the integers $\mathbb{Z}$, the indecomposables are interval modules, which implies that $M$ is isomorphic to a direct sum of interval modules $\oplus \mathbb{Z}[[b_\alpha, d_\alpha]]$, for integers $b_\alpha \leq d_\alpha$ and $\alpha$ in some index set $A$. This follows from a classification theorem for quiver representations established by Pierre Gabriel in the 1970s. The multiset of intervals $\{[b_\alpha, d_\alpha] \mid \alpha \in A\}$ that appear in this decomposition constitutes the persistence diagram, or equivalently, the barcode of $M$ – a central object in TDA [19, 21].
There are many situations in which data naturally induce persistence modules over posets which are different from $\mathbb{Z}$. Unfortunately, the situation already becomes “wild” when the domain poset is $\mathbb{Z}^2$. In that situation, one must contend with the fact that a direct analogue of the notion of persistence diagrams may not exist [14], namely it may not be possible to obtain a lossless up-to-isomorphism representation of the module as a direct sum of interval modules.

Much energy has been put into finding ways in which one can extract incomplete but still stable invariants from persistence modules $M : \mathbb{Z}^d \to \text{vec}$ (which we will refer to as a $\mathbb{Z}^d$-module). Biasotti et al. [6] proposed considering the restriction of a $\mathbb{Z}^d$-module to lines with positive slope. This was further developed by Lesnick and Wright in the RIVET project [31] which facilitates the interactive visualization of $\mathbb{Z}^2$-modules. Cai et al. [11] considered a certain elder-rule on the $\mathbb{Z}^2$-modules which arise in multiparameter clustering. Other efforts have identified algebraic conditions which can guarantee that $M$ can be decomposed into interval modules of varying degrees of complexity (e.g. rectangle modules etc) [7, 16].

A distinct thread has been proposed by Patel in [35] through the reinterpretation of the persistence diagram of a $\mathbb{Z}$-module as the Möbius inversion of its rank function. Patel’s work was then extended by Kim and Mémoli [26] to the setting of modules defined over any suitable locally finite poset. They generalized the rank invariant via the *limit-to-colimit map* over subposets and then conveniently expressed its Möbius inversion. In fact the limit-to-colimit map was suggested by Amit Patel to the authors of [26] who in [25] used it to define a notion

![Figure 1 Generalized rank via zigzag persistence](image-url)
of rank invariant for zigzag modules. Chambers and Letscher [15] also considered a notion of persistent homology over directed acyclic graphs using the limit-to-colimit map. Asashiba et al. [2] study the case of modules defined on an \(m \times n\) grid and propose a high-level algorithm for computing both their generalized rank function and their Möbius inversions with the goal of providing an approximation of a given module by interval decomposables. Asashiba et al. [1] tackle the interval decomposability of a given \(\mathbb{Z}^2\)-module via quiver representation theory.

One fundamental algorithmic problem is that of determining whether a given \(\mathbb{Z}^2\)-module is interval decomposable, and if so, computing the intervals. There are some existing solutions to this problem in the literature. Suppose that the input \(\mathbb{Z}^2\)-module is induced by a bifiltration comprising at most \(t\) simplices on a grid of cardinality \(O(t)\). First, the decomposition algorithm by Dey and Xin [20] can produce all indecomposables from such a module in \(O(t^{2\omega+1})\) time (see [24] for comments about its implementation) where \(\omega \in [2,2.373]\) is the exponent of matrix multiplication. Given these indecomposables, one could then test whether they are indeed interval modules. However, the algorithm requires that the input module be such that no two generators or relations in the module have the same grade. Then, Asashiba et al. [1] give an algorithm which requires enumerating an exponential number (in \(t\)) of intervals. Finally, the algorithm by Meataxe sidesteps both of the above issues, but incurs a worst-case cost of \(O(t^{18})\) as explained in [20].

See also [5, 9, 10, 28, 32] for related recent work.

**Contributions.** One of our key results is the following. We prove that for an interval \(I\) in \(\mathbb{Z}^2\) we can compute the generalized rank invariant \(\text{rk}(M(I))\) of a \(\mathbb{Z}^2\)-module \(M\) through the computation of the zigzag persistence barcode of the restriction of \(M\) to the boundary cap of \(I\), which is a certain zigzag path in \(I\); see Figure 1 for an illustration.

These are our main results assuming that the input is a bifiltration with \(O(t)\) simplices:
1. We reduce the problem of computing the generalized rank invariant of a \(\mathbb{Z}^2\)-module to computing zigzag persistence (Theorem 24).
2. We provide an algorithm \textsc{Interval} (page 13) to compute the barcode of any finite interval decomposable \(\mathbb{Z}^2\)-module in time \(O(t^{\omega+2})\) (Proposition 38).
3. We provide an algorithm \textsc{IsIntervalDecomp} (page 15) to decide the interval decomposability of a finite \(\mathbb{Z}^2\)-module in time \(O(t^{3\omega+2})\) (Proposition 39).

# 2 Preliminaries

In §2.1, we review the notion of interval decomposability of persistence modules. In §2.2, we review the notions of generalized rank invariant and generalized persistence diagram. In §2.3, we discuss how to compute the limit and the colimit of a given functor \(P \to \text{vec}\).

## 2.1 Persistence Modules and their decompositions

We fix a certain field \(\mathbb{F}\) and every vector space in this paper is over \(\mathbb{F}\). Let \(\text{vec}\) denote the category of finite dimensional vector spaces and linear maps over \(\mathbb{F}\).

Let \(P\) be a poset. We regard \(P\) as the category that has points of \(P\) as objects. Also, for any \(p,q \in P\), there exists a unique morphism \(p \to q\) if and only if \(p \leq q\). For a positive integer \(d\), let \(\mathbb{Z}^d\) be given the partial order defined by \((a_1,a_2,\ldots,a_d) \leq (b_1,b_2,\ldots,b_d)\) if and only if \(a_i \leq b_i\) for \(i = 1,2,\ldots,d\).

A \((P\text{-indexed})\) **persistence module** is any functor \(M : P \to \text{vec}\) (which we will simply refer to as a \(P\)-module). In other words, to each \(p \in P\), a vector space \(M_p\) is associated, and to each pair \(p \leq q\) in \(P\), a linear map \(\varphi_M(p,q) : M_p \to M_q\) is associated. Importantly, whenever \(p \leq q \leq r\) in \(P\), it must be that \(\varphi_M(p,r) = \varphi_M(q,r) \circ \varphi_M(p,q)\).
Generalized Rank via Zigzag and Its Applications

We say that a pair of $p, q \in P$ is **comparable** if either $p \leq q$ or $q \leq p$.

**Definition 1 ([8]).** An interval $I$ of $P$ is a subset $I \subseteq P$ such that:

(i) $I$ is nonempty.
(ii) If $p, q \in I$ and $p \leq r \leq q$, then $r \in I$.
(iii) $I$ is connected, i.e., for any $p, q \in I$, there is a sequence $p = p_0, p_1, \ldots, p_\ell = q$ of elements of $I$ with $p_i$ and $p_{i+1}$ comparable for $0 \leq i \leq \ell - 1$.

By $\text{Int}(P)$ we denote the set of all finite intervals of $P$. When $P$ is finite and connected, $P \in \text{Int}(P)$ will be referred to as the **full interval**.

For an interval $I$ of $P$, the **interval module** $I_I : P \rightarrow \text{vec}$ is defined as

$$
\mathbb{I}_I(p) = \begin{cases} 
F & \text{if } p \in I, \\
0 & \text{otherwise},
\end{cases}
\quad \varphi_I(p, q) = \begin{cases} 
\text{id}_F & \text{if } p, q \in I, p \leq q, \\
0 & \text{otherwise}.
\end{cases}
$$

Direct sums and quotients of $P$-modules are defined pointwisely at each index $p \in P$.

**Definition 2.** Let $M$ be any $P$-module. A submodule $N$ of $M$ is defined by subspaces $N_p \subseteq M_p$ such that $\varphi_M(p, q)(N_p) \subseteq N_q$ for all $p, q \in P$ with $p \leq q$. These conditions guarantee that $N$ itself is a $P$-module, with the structure maps given by the restrictions $\varphi_M(p, q)|_{N_p}$. In this case we write $N \leq M$.

A submodule $N$ is a **summand** of $M$ if there exists a submodule $N'$ which is complementary to $N$, i.e., $M_p = N_p \oplus N'_p$ for all $p$. In that case, we say that $M$ is a direct sum of $N, N'$ and write $M \cong N \oplus N'$. Note that this direct sum is an internal direct sum.

**Definition 3.** A $P$-module $M$ is called interval decomposable if $M$ is isomorphic to a direct sum of interval modules, i.e., there exists an indexing set $\mathcal{J}$ such that $M \cong \bigoplus_{j \in \mathcal{J}} I_j$ (external direct sum). In this case, the multiset $\{I_j : j \in \mathcal{J}\}$ is called the barcode of $M$, which will be denoted by $\text{barc}(M)$.

The Azumaya-Krull-Remak-Schmidt theorem guarantees that $\text{barc}(M)$ is well-defined [3]. Consider a zigzag poset of $n$ points, $\bullet_1 \leftrightarrow \bullet_2 \leftrightarrow \ldots \leftrightarrow \bullet_{n-1} \leftrightarrow \bullet_n$, where $\leftrightarrow$ stands for either $\leq$ or $\geq$. A functor from a zigzag poset to $\text{vec}$ is called a **zigzag module** [12]. Any zigzag module is interval decomposable [23] and thus admits a barcode.

The following proposition directly follows from the Azumaya-Krull-Remak-Schmidt theorem and will be useful in §4.

**Proposition 4.** Let $M : P \rightarrow \text{vec}$ be interval decomposable and let $N \leq M$ is a summand of $M$ (Definition 2). Then, $M/N$ is interval decomposable (proof in the full version).

### 2.2 Generalized rank invariant and generalized persistence diagrams

Let $P$ be a finite connected poset and consider any $P$-module $M$. Then $M$ admits a limit $\varprojlim M = (L_r(\pi_p : P \rightarrow M_p))_{p \in P}$ and a colimit $\varinjlim M = (C, (i_p : M_p \rightarrow C)_{p \in P})$; see the full version for definitions. This implies that, for every $p \leq q$ in $P$, $\varphi_M(p \leq q) \circ \pi_p = \pi_q$ and $i_q \circ \varphi_M(p \leq q) = i_p$, which in turn imply $i_p \circ \pi_p = i_q \circ \pi_q : L \rightarrow C$ for any $p, q \in P$.

**Definition 5 ([126]).** The **canonical limit-to-colimit map** $\psi_M : \varprojlim M \rightarrow \varinjlim M$ is the linear map $i_p \circ \pi_p$ for any $p \in P$. The **generalized rank** of $M$ is $\text{rank}(M) := \text{rank}(\psi_M)$.

The rank of $M$ counts the multiplicity of the fully supported interval modules in a direct sum decomposition of $M$.

**Theorem 6 ([15, Lemma 3.1]).** The rank of $M$ is equal to the number of indecomposable summands of $M$ which are isomorphic to the interval module $I_p$. 
Definition 7. The (Int)-generalized rank invariant of $M$ is the map $\text{rk}_I(M) : \text{Int}(P) \to \mathbb{Z}_+$ defined as $I \mapsto \text{rank}(M|_I)$, where $M|_I$ is the restriction of $M$ to $I$.

Definition 8. The (Int)-generalized persistence diagram of $M$ is the unique\(^1\) function $\text{dgm}_I(M) : \text{Int}(P) \to \mathbb{Z}$ that satisfies, for any $I \in \text{Int}(P)$,

$$\text{rk}_I(M)(I) = \sum_{J \supseteq I} \text{dgm}_I(M)(J).$$

The following is a slight variation of [26, Theorem 3.14] and [2, Theorem 5.10].

Theorem 9. If a given $M : P \to \text{vec}$ is interval decomposable, then for all $I \in \text{Int}(P)$, $\text{dgm}_I(M)(I)$ is equal to the multiplicity of $I$ in $\text{barc}(M)$ (proof in the full version).

We consider $P$ to be a 2d-grid and focus on the setting of $\mathbb{Z}^2$-modules.

Definition 10. For any $I \in \text{Int}(\mathbb{Z}^2)$, we define $\text{nbd}_I(I) := \{p \in \mathbb{Z}^2 \setminus I : I \cup \{p\} \in \text{Int}(\mathbb{Z}^2)\}$. Note that $\text{nbd}_I(I)$ is nonempty [2, Proposition 3.2]. When $A \subseteq \text{nbd}_I(I)$ contains more than one point, $A \cup I$ is not necessarily an interval of $\mathbb{Z}^2$. However, there always exists a unique smallest interval that contains $A \cup I$ which is denoted by $\overline{A \cup I}$.

Remark 11 ([2, Theorem 5.3]). If in Definition 8 we assume that $P \in \text{Int}(\mathbb{Z}^2)$ then we have that for every $I \in \text{Int}(P)$,\(^2\)

$$\text{dgm}_I(M)(I) = \text{rk}_I(M)(I) + \sum_{A \subseteq \text{nbd}_I(I) \cap P : A \neq \emptyset} (-1)^{|A|} \text{rk}_I(M)(\overline{A \cup I}). \quad (1)$$

2.3 Canonical constructions of limits and colimits

Let $M$ be any $P$-module.

Notation 12. Let $p, q \in P$ and let $v_p \in M_p$ and $v_q \in M_q$. We write $v_p \sim v_q$ if $p$ and $q$ are comparable, and either $v_p$ is mapped to $v_q$ via $\varphi_M(p, q)$ or $v_q$ is mapped to $v_p$ via $\varphi_M(q, p)$.

The following proposition gives a standard way of constructing a limit and a colimit of a $P$-module $M$. Since it is well-known, we do not prove it (see for example [26, Section E]).

Proposition 13.

(i) The limit of $M$ is (isomorphic to) the pair $(W, (\pi_p)_{p \in P})$ where:

$$W := \left\{(v_p)_{p \in P} \in \bigoplus_{p \in P} M_p : \forall p \leq q \in P, v_p \sim v_q \right\} \quad (2)$$

and for each $p \in P$, the map $\pi_p : W \to M_p$ is the canonical projection. An element of $W$ is called a section of $M$.

(ii) The colimit of $M$ is (isomorphic to) the pair $(U, (i_p)_{p \in P})$ described as follows: For $p \in P$, let the map $j_p : M_p \hookrightarrow \bigoplus_{p \in P} M_p$ be the canonical injection. $U$ is the quotient \left(\bigoplus_{p \in P} M_p\right)/T$, where $T$ is the subspace of $\bigoplus_{p \in P} M_p$ which is generated by the vectors of the form $j_p(v_p) - j_q(v_q)$, $v_p \sim v_q$, the map $i_p : M_p \to U$ is the composition $\rho \circ j_p$, where $\rho$ is the quotient map $\bigoplus_{p \in P} M_p \to U$.

---

\(^1\) The existence and uniqueness is guaranteed by properties of the Möbius inversion formula [36, 37].

\(^2\) In [2], only the case $P = \{1, \ldots, m\} \times \{1, \ldots, n\} \subset \mathbb{Z}^2$ was considered. However, it is not difficult to check that Eq. (1) is still valid for any finite interval $P$ in $\mathbb{Z}^2$ and any subinterval $I \subseteq P$. 

---

SoCG 2022
Setup 1. In the rest of the paper, limits and colimits of a \( P \)-module \( M \) will all be constructed as in Proposition 13. Hence, assuming that \( P \) is connected, the canonical limit-to-colimit map \( \lim \leftarrow M \to \lim \rightarrow M \) is \( \psi_M := i_p \circ \pi_p \) for any \( p \in P \).

3 Computing generalized rank via boundary zigzags

In §3.1 we introduce the notions of lower and upper fences of a poset. In §3.2, we introduce the boundary cap \( \partial I \) of a finite interval \( I \) of \( \mathbb{Z}^2 \), which is a path, a certain sequence of points in \( I \). In §3.3, we show that the rank of any functor \( M : I \to \textbf{vec} \) can be obtained by computing the barcode of the zigzag module over the path \( \partial I \).

3.1 Lower and upper fences of a poset

Let \( P \) be any connected poset. Given any \( p \in P \), by \( p \downarrow \), we denote the set of all elements of \( P \) that are less than or equal to \( p \). Dually \( p \uparrow \) is defined as the set of all elements of \( P \) that are greater than or equal to \( p \).

Definition 14. A subposet \( L \subset P \) (resp. \( U \subset P \)) is called a lower (resp. upper) fence of \( P \) if \( L \) is connected, and for any \( q \in P \), the intersection \( L \cap q \downarrow \) (resp. \( U \cap q \uparrow \)) is nonempty and connected.

Proposition 15. Let \( L \) and \( U \) be a lower and an upper fences of \( P \) respectively. Given any \( P \)-module \( M \), we have \( \lim \leftarrow M \cong \lim \leftarrow M \upharpoonright L \) and \( \lim \rightarrow M \cong \lim \rightarrow M \upharpoonright U \) (proof in the full version).

The canonical isomorphism \( \lim M \cong \lim M \upharpoonright L \) in Proposition 15 is given by the canonical section extension \( e : \lim \leftarrow M \upharpoonright L \to \lim \rightarrow M \). Namely,

\[
e : (v_p)_{p \in L} \mapsto (w_q)_{q \in P},
\]
where for any \( q \in P \), the vector \( w_q \) is defined as \( \varphi_M(p,q)(v_p) \) for any \( p \in L \cap q \downarrow \); the connectedness of \( L \cap q \downarrow \) guarantees that \( w_q \) is well-defined. Also, if \( q \in L \), then \( w_q = v_q \). The inverse \( r := e^{-1} \) is the canonical section restriction. The other isomorphism \( \lim M \cong \lim M \upharpoonright U \) in Proposition 15 is given by the map \( i : \lim \rightarrow M \upharpoonright U \to \lim \rightarrow M \) defined by \( [v_p] \mapsto [v_p] \) for any \( p \in U \) and any \( v_p \in M_p \); the fact that this map \( i \) is well-defined will become clear from Proposition 22. Let us define \( \xi : \lim \leftarrow M \to \lim \rightarrow M \) by \( r^{-1} \circ \psi_M \circ e \). By construction, the following diagram commutes

\[
\begin{array}{ccc}
\lim M \upharpoonright L & \xrightarrow{\xi} & \lim M \upharpoonright U \\
\cong & \searrow & \cong \\
\lim M & \xrightarrow{\psi_M} & \lim M,
\end{array}
\]
where \( \psi_M \) is the canonical limit-to-colimit map of \( M \). Hence we have the fact \( \text{rank}(\psi_M) = \text{rank}(\xi) \), which is useful for proving Theorem 24.

This proposition appeared in an earlier version of [26] (see Proposition D.14 in the second arXiv version).
Five different intervals $I$ of $Z^2$. Relations in $\min_{Z^2}(I)$ and $\max_{Z^2}(I)$ are indicated by green and red arrows, respectively. The inequality $p_0 \leq q_0$ is indicated by blue arrows unless $p_0 = q_0$. Notice that $\partial I$, as defined in equation (7), has cardinality 2, 2, 6, 6, 6 in that order ((A),(B),(C),(D),(E)).

3.2 Boundary cap of an interval in $Z^2$

Let $I \in \text{Int}(Z^2)$, i.e. $I$ is a finite interval of $Z^2$ (Definition 1). By $\min(I)$ and $\max(I)$, we denote the collections of minimal and maximal elements of $I$, respectively. In other words, $\min(I) := \{p \in I : \text{there is no } q \in I \text{ s.t. } q < p\}$, 
$\max(I) := \{p \in I : \text{there is no } q \in I \text{ s.t. } p < q\}$.

Note that $\min(I)$ and $\max(I)$ are nonempty and that $\min(I)$ and $\max(I)$ respectively form an antichain in $I$, i.e. any two different points in $\min(I)$ (or in $\max(I)$) are not comparable.

\begin{itemize}
\item[(i)] The least upper bound and the greatest lower bound of $p, q \in Z^2$ are denoted by $p \lor q$ and $p \land q$ respectively. Let $p = (p_x, p_y)$ and $q = (q_x, q_y)$ in $Z^2$. Then,
\[ p \lor q = (\max\{p_x, q_x\}, \max\{p_y, q_y\}), \quad p \land q = (\min\{p_x, q_x\}, \min\{p_y, q_y\}). \]
\end{itemize}

For the item below, let $I \in \text{Int}(Z^2)$. Notice the following:
\begin{itemize}
\item[(ii)] Since $\min(I)$ is a finite antichain, we can list the elements of $\min(I)$ in ascending order of their $x$-coordinates, i.e. $\min(I) := \{p_0, \ldots, p_k\}$ and such that for each $i = 0, \ldots, k$, the $x$-coordinate of $p_i$ is less than that of $p_{i+1}$. Similarly, let $\max(I) := \{q_0, \ldots, q_\ell\}$ be ordered in ascending order of $q_i$’s $x$-coordinates. We have that $p_0 \leq q_0$ (Figure 2).
\end{itemize}

\begin{itemize}
\item[Definition 17 (Lower and upper zigzags of an interval).] Let $I$, $\min(I)$, and $\max(I)$ be as in Remark 16 ii. We define the following two zigzag posets (Figure 2):
\begin{align*}
\min_{Z^2}(I) &:= \{p_0 < (p_0 \lor p_1) < p_1 < (p_1 \lor p_2) < \cdots < (p_{k-1} \lor p_k) > p_k\} \quad (5) \\
&= \min(I) \cup \{p_i \lor p_{i+1} : i = 0, \ldots, k-1\}, \\
\max_{Z^2}(I) &:= \{q_0 > (q_0 \land q_1) > q_1 > (q_1 \land q_2) > \cdots > (q_{\ell-1} \land q_\ell) > q_\ell\} \quad (6) \\
&= \max(I) \cup \{q_i \land q_{i+1} : i = 0, \ldots, \ell-1\}.
\end{align*}
\end{itemize}
Note that \( \min \vec{ZZ}(I) \) and \( \max \vec{ZZ}(I) \) are lower and upper fences of \( I \) respectively.

For \( p, q \in P \), let us write \( p \prec q \) if \( p < q \) and there is no \( r \in P \) such that \( p < r < q \). Similarly, we write \( p \succ q \) if \( p > q \) and there is no \( r \in P \) such that \( p > r > q \).

Definition 18. Given a poset \( P \), a path \( \Gamma \) between two points \( p, q \in P \) is a sequence of points \( p = p_0, \ldots, p_k = q \) in \( P \) such that either \( p_i \leq p_{i+1} \) or \( p_i \geq p_{i+1} \) for every \( i \in [1, k-1] \) (in particular, there can be a pair \( i \neq j \) such that \( p_i = p_j \)). The path \( \Gamma \) is said to be \textbf{monotonic} if \( p_i \leq p_{i+1} \) for each \( i \). The path \( \Gamma \) is called \textbf{faithful} if either \( p_i < p_{i+1} \) or \( p_i > p_{i+1} \) for each \( i \).

Definition 19 (Boundary cap of an interval). We define the \textbf{boundary cap} \( \partial I \) of \( I \in \text{Int}(\mathbb{Z}^2) \) as the path obtained by concatenating \( \min \vec{ZZ}(I) \) and \( \max \vec{ZZ}(I) \) in Eqs. (5) and (6).

\[
\partial I := \begin{cases} p_k < (p_k \lor p_{k-1}) < p_{k-1} < \cdots < p_0 \leq (q_0 \land q_1) < q_1 < \cdots < q_\ell, & \text{if } 2k+1 \text{ terms from } \min \vec{ZZ}(I) \\ p_1 < p_2 < \cdots < p_i < \cdots < p_{2\ell+1} & \text{if } 2\ell+1 \text{ terms from } \max \vec{ZZ}(I) \end{cases}
\]

We remark that \( \partial I \) can contain multiple copies of the same point. Namely, there can be \( i \in [0, k] \) and \( j \in [0, \ell] \) such that either \( p_i = q_j \) (Figure 2 (A)), \( p_i = q_j \lor q_{j+1} \) (Figure 2 (C)), \( p_i \lor p_{i+1} = q_j \) (Figure 2 (C)), or \( p_i \lor p_{i+1} = q_j \lor q_{j+1} \) (Figure 2 (D)).

Consider the following zigzag poset of the same length as \( \partial I \):

\[
\vec{ZZ}_{\partial I} : \begin{array}{c} \bullet_1 < \bullet_2 > \bullet_3 < \cdots < \bullet_{2k+1} < \circ_1 > \circ_2 < \circ_3 > \cdots < \circ_{2\ell+1} \end{array}
\]

Still using the notation in Eqs. (7) we have the following order-preserving map

\[
\iota_I : \vec{ZZ}_{\partial I} \rightarrow I
\]

whose image is \( \partial I \): \( \bullet_1 \) is sent to \( p_k \), \( \bullet_2 \) is sent to \( p_k \lor p_{k-1} \), ..., and \( \circ_{2\ell+1} \) is sent to \( q_\ell \).

3.3 Generalized rank invariant via boundary zigzags

The goal of this section is to establish Theorem 24.

Definition 20. Let \( P \) be a poset. Let \( \Gamma : p_0, \ldots, p_k \) be a path in \( P \). An \((k+1)\)-tuple \( \vec{v} \in \bigoplus_{i=0}^k M_{p_i} \) is called the \textbf{section of} \( M \) along \( \Gamma \) if \( v_{p_i} \sim \vec{v}_{p_{i+1}} \) for each \( i \) (Notation 12).

Note that \( \vec{v} \) is not necessarily a section of the restriction \( M|_{\{p_0, \ldots, p_k\}} \) of \( M \) to the subposet \( \{p_0, \ldots, p_k\} \subseteq I \). Furthermore, \( \Gamma \) can contain multiple copies of the same point in \( P \).

Example 21. Consider \( M : \{(1, 1), (1, 2), (2, 2), (2, 1)\}(\subset \mathbb{Z}^2) \rightarrow \text{vec} \) given as follows.

\[
\begin{array}{c|c|c} \hline M_{(1,2)} & M_{(2,2)} & \mathbb{F}^4 \\\hline M_{(1,1)} & M_{(2,1)} & \mathbb{F}^{(1,1)} \\\hline \end{array}
\]

Consider the path \( \Gamma : (1, 1), (1, 2), (2, 2), (2, 1) \) which contains all points in the indexing poset. Then, \( \vec{v} := (1, 1, 1, (0, 1)) \in M_{(1,1)} \oplus M_{(1,2)} \oplus M_{(2,2)} \oplus M_{(2,1)} \) is a section of \( M \) along \( \Gamma \), while \( \vec{v} \) is not a section of \( M \) itself, i.e. \( \vec{v} \not\in \lim_{\leftarrow} M \).
By Proposition 13 (ii), we directly have:

**Proposition 22.** Let $p,q \in P$. For any vectors $v_p \in M_p$ and $v_q \in M_q$ $[v_p] = [v_q]$ if and only if there exist a path $\Gamma : p = p_0, p_1, \ldots, p_n = q$ in $P$ and a section $\psi$ of $M$ along $\Gamma$ such that $v_p = \psi_f v_q$.

The map $\iota_I : \text{ZZ}_{\partial I} \to I$ in Eqs. (9) induces a bijection between the sections of $M_{\partial I}$ and the sections of $M$ along $\partial I$ in a canonical way. Hence:

**Setup 2.** In the rest of §3.3, we fix both $I \in \text{Int}(Z^2)$ and a functor $M : I \to \text{vec}$. Each element in $\lim M_{\partial I}$ is identified with the corresponding section of $M$ along $\partial I$. Also, we identify points in (7) and (8) via $\iota_I$.

**Definition 23** (Zigzag module along $\partial I$). Define the zigzag module $M_{\partial I} : \text{ZZ}_{\partial I} \to \text{vec}$ by $(M_{\partial I})_x := M_{I(x)}$ for $x \in \text{ZZ}_{\partial I}$ and $\varphi_{M_{\partial I}}(x,y) := \varphi_M(\iota_I(x), \iota_I(y))$ for $x \leq y$ in $\text{ZZ}_{\partial I}$.

One of our main results is the following.

**Theorem 24.** rank$(M)$ is equal to the multiplicity of the full interval in $\text{barc}(M_{\partial I})$.

**Proof.** By Theorem 6, it suffices to show that

$$\text{rank}(\psi_M : \lim M \to \lim M) = \text{rank}(\psi_{M_{\partial I}} : \lim M_{\partial I} \to \lim M_{\partial I}).$$

Let $L := \min_{\text{ZZ}}(I)$ and $U := \max_{\text{ZZ}}(I)$ which are lower and upper fences of $I$ respectively. Let us define the maps $e,r,i$ and $\xi$ as described in the paragraph after Proposition 15. Then, by Proposition 15 and the commutative diagram in (4), it suffices to prove that the rank of $\xi$ equals the rank of $\psi_{M_{\partial I}}$. To this end, we show that there exist a surjective linear map $f : \lim M_{\partial I} \to \lim M|_L$ and an injective linear map $g : \lim M|_U \to \lim M_{\partial I}$ such that $\psi_{M_{\partial I}} = g \circ \xi \circ f$. We define $f$ as the canonical section restriction $(v_q)_{q \in \partial I} \mapsto (v_q)_{q \in L}$. We define $g$ as the canonical map, i.e. $[v_q] \mapsto [v_q]$ for any $q \in U$ and any $v_q \in M_q$. By Proposition 22 and by construction of $M_{\partial I}$, the map $g$ is well-defined.

We now show that $\psi_{M_{\partial I}} = g \circ \xi \circ f$. Let $\psi := (v_q)_{q \in \partial I} \in \lim M_{\partial I}$. Then, by definition of $\psi_{M_{\partial I}}$ (Setup 1), the image of $\psi$ via $\psi_{M_{\partial I}}$ is $[v_{q_0}]$ where $q_0 \in U$ is defined as in Remark 16 ii. Also, we have

$$\psi \xrightarrow{f} (v_q)_{q \in L} \xrightarrow{\xi} [v_{q_0}] \xrightarrow{g} [v_{q_0}] \in \lim M_{\partial I},$$

which proves the equality $\psi_{M_{\partial I}} = g \circ \xi \circ f$.

We claim that $f$ is surjective. Let $r' : \lim M \to \lim M_{\partial I}$ be the canonical section restriction map $(v_q)_{q \in I} \mapsto (v_q)_{q \in \partial I}$. Then, the restriction $r : \lim M \to \lim M|_L$, can be seen as the composition of two restrictions $r = f \circ r'$. Since $r$ is the inverse of the isomorphism $e$ in diagram (4), $r$ is surjective and thus so is $f$.

Next we claim that $g$ is injective. Let $i' : \lim M_{\partial I} \to \lim M$ be defined by $[v_q] \mapsto [v_q]$ for any $q \in \partial I$ and any $v_q \in M_q$. By Proposition 22 and by construction of $M_{\partial I}$, the map $i'$ is well-defined. Then, for the isomorphism $i$ in diagram (4), we have $i = i' \circ g$. This implies that $g$ is injective.

---

4 For simplicity, we write $[v_q]$ and $[v_q]$ instead of $[j_p(v_p)]$ and $[j_q(v_q)]$ respectively where $j_p : M_p \to \bigoplus_{r \in P} M_r$ and $j_q : M_q \to \bigoplus_{r \in P} M_r$ are the canonical inclusion maps.
Remark 25. In Definition 19 one may consider the “lower” boundary cap $\tilde{\partial I}$, as an alternative to $\partial I$:

\[
\tilde{\partial I} : p_0 < p_0 \lor p_1 > p_1 < \cdots > p_k \leq q_t > q_t \land q_{t-1} < q_{t-1} > \cdots < q_0.
\]

The value $\text{rank}(M)$ also equals the multiplicity of the full interval in the barcode of the zigzag module induced over $\tilde{\partial I}$.

By Theorem 24, we can utilize algorithms for zigzag persistence in order to compute the generalized rank invariant and the generalized persistence diagram of any $\mathbb{Z}_2$-module that is obtained by applying the homology functor to a finite simplicial bifiltration consisting of $O(t)$ simplices over an index set of size $O(t)$. For this, we complete the boundary cap of a given interval to a faithful path (i.e. we put the missing monotonic paths between every pair of consecutive points) and then simply run a zigzag persistence algorithm, say the $O(t^\omega)$ algorithm of Milosavljevic et al. [34], on the filtration restricted to this path.

Remark 26. To compute $dgm_I(M)(I)$ by the formula in (1), one needs to consider terms whose number depends exponentially on the number of neighbors of $I$. However, for any interval that has at most $O(\log t)$ neighbors, we have $2^{O(\log t)} = t^c$ terms for some constant $c > 0$. It follows that using $O(t^c)$ zigzag persistence algorithm for computing generalized ranks, we obtain an $O(t^{c+\epsilon})$ algorithm for computing generalized persistence diagrams of intervals that have at most $O(\log t)$ neighbors.

4 Computing intervals and detecting interval decomposability

When a persistence module $M$ admits a summand $N$ that is isomorphic to an interval module, $N$ will be called an interval summand of $M$. In this section, we apply Theorem 24 for computing generalized rank via zigzag to different problems that ask to find interval summands of an input finite $\mathbb{Z}_2$-module: Problems I, II, and III.

Let $K$ be a finite abstract simplicial complex and let $\text{sub}(K)$ be the poset of all subcomplexes of $K$, ordered by inclusion. Given any poset $P$, an order-preserving map $\mathcal{F} : P \rightarrow \text{sub}(K)$ is called a simplicial filtration (of $K$).

Setup 3. Throughout §4, $\mathcal{F}$ denotes a bifiltration of a simplicial complex $K$ defined over an interval $P \in \text{Int}(\mathbb{Z}_2)$. Let $t := \max(|K|, |P|)$ denote the maximum of the number of simplices in $K$ and the number of points in $P$. By $M_{\mathcal{F}} : P \rightarrow \text{vec}$ we denote the module induced by $\mathcal{F}$ through the homology functor with coefficients in the field $F$.

Computing the dimension function. In all algorithms below, we utilize a subroutine $\text{DIM}(\mathcal{F}, P)$, which computes the dimension of the vector space $(M_{\mathcal{F}})_p$ for every $p \in P$.

Proposition 27. $\text{DIM}(\mathcal{F}, P)$ can be executed in $O(t^3)$ time (proof in the full version).

4.1 Detecting interval modules

We consider the following problem.
Then, \( M \) is isomorphic to the direct sum of a certain number of copies of \( I_p \) and if so, report the number of such copies.

Algorithm \textsc{IsInterval} solves Problem I. The correctness of the algorithm follows from Proposition 28. Below, for an interval \( I \in \text{Int}(\mathbb{Z}^2) \) and for \( m \in \mathbb{Z}_{\geq 0} \) we define \( I^m := \bigoplus_{i=1}^{m} I \). In particular, \( I^0 \) is defined to be the trivial module. Let us recall that \( (M_{\mathbf{F}})_{\partial P} \) denotes the zigzag module along the boundary cap \( \partial P \) (Definition 23).

\begin{algorithm}
\caption{\textsc{IsInterval}(\mathbf{F}, P).}
\begin{itemize}
\item Step 1. Compute zigzag barcode \( \text{barc}((M_{\mathbf{F}})_{\partial P}) \) and let \( m \) be the multiplicity of the full interval.
\item Step 2. Call \text{DIM}(\mathbf{F}, P) (Computes \( \dim(M_{\mathbf{F}})_p \) for every \( p \in P \))
\item Step 3. If \( \dim(M_{\mathbf{F}})_p = m \) for each point \( p \in P \) return \( m \), otherwise return 0 indicating \( M_{\mathbf{F}} \) has a summand which is not an interval module supported over \( P \).
\end{itemize}
\end{algorithm}

\begin{proposition}
Assume that a given \( M : P \to \text{vec} \) has the indecomposable decomposition \( M \cong \bigoplus_{i=1}^{m} M_i \). Then, every summand \( M_i \) is isomorphic to the interval module \( I_p \) if and only if \( \text{rk}_0(M)(P) = \dim M_p = m \) for all \( p \in P \) (proof in the full version).
\end{proposition}

\begin{proposition}
Algorithm \textsc{IsInterval} can be run in \( O(t^3) \) time (proof in the full version).
\end{proposition}

### 4.2 Interval decomposable modules and its summands

Setup 3 still applies in §4.2. Next, we consider the problem of computing all indecomposable summands of \( M_{\mathbf{F}} \) under the assumption that \( M_{\mathbf{F}} \) is interval decomposable (Definition 3).

\begin{proposition}
Assume that \( M_{\mathbf{F}} : P \to \text{vec} \) is interval decomposable. Find \( \text{barc}(M_{\mathbf{F}}) \).
\end{proposition}

We present algorithm \textsc{Interval} to solve Problem II in \( O(t^{\omega+2}) \) time. This algorithm is eventually used to detect whether a given module is interval decomposable or not (Problem III). Before describing \textsc{Interval}, we first describe another algorithm \textsc{TrueInterval}. The outcomes of both \textsc{Interval} and \textsc{TrueInterval} are the same as the barcode of \( M_{\mathbf{F}} \) in Problem II (Propositions 33 and 37). Whereas \textsc{TrueInterval} is more intuitive, real implementation is accomplished via \textsc{Interval}.

\begin{definition}
Let \( \mathcal{I}(M_{\mathbf{F}}) := \{ I \in \text{Int}(P) : \text{rk}_0(M_{\mathbf{F}})(I) > 0 \} \). We call \( I \in \mathcal{I}(M_{\mathbf{F}}) \) maximal if there is no \( J \supsetneq I \) in \( \text{Int}(P) \) such that \( \text{rk}_0(M_{\mathbf{F}})(J) \) is nonzero.
\end{definition}

\begin{proposition}
Assume that \( M_{\mathbf{F}} \) is interval decomposable and let \( I \in \mathcal{I}(M_{\mathbf{F}}) \) be maximal. Then, \( I \) belongs to \( \text{barc}(M_{\mathbf{F}}) \) and the multiplicity of \( I \) in \( \text{barc}(M_{\mathbf{F}}) \) is equal to \( \text{rk}_0(M_{\mathbf{F}})(I) \).
\end{proposition}

\begin{proof}
By assumption, all summands in the sum
\[
\sum_{\substack{A \subseteq \text{nbd}(I) \cap P \\ A \neq \emptyset}} (-1)^{|A|} \text{rk}_0(M_{\mathbf{F}}) \left( \overline{I \cup A} \right)
\]

for the second term of (1) are zero. Hence, \( \text{dgm}_1(M_{\mathbf{F}})(I) = \text{rk}_0(M_{\mathbf{F}})(I) > 0 \). Since \( M_{\mathbf{F}} \) is interval decomposable, by Theorem 9, \( \text{dgm}_1(M_{\mathbf{F}})(I) \) is equal to the multiplicity of \( I \) in \( \text{barc}(M_{\mathbf{F}}) \). Therefore, not only does \( I \) belong to \( \text{barc}(M_{\mathbf{F}}) \), but also the value \( \text{rk}_0(M_{\mathbf{F}})(I) \) is equal to the multiplicity of \( I \) in \( \text{barc}(M_{\mathbf{F}}) \).
\end{proof}

The following proposition is a corollary of Proposition 31.
Proposition 32. Assume that $M_F$ is interval decomposable and let $I \in \mathcal{I}(M_F)$ be maximal. Let $\mu_I := \text{rk}_q(M_F)(I)$. Then, $M_F$ admits a summand $N$ which is isomorphic to $I^\mu_I$.

Let us now describe a procedure `TrueInterval` that outputs all indecomposable summands of a given interval decomposable module. For computational efficiency, we will implement `TrueInterval` differently. Let $M := M_F$. First we compute $\dim M_p$ for every point $p \in P$. Iteratively, we choose a point $p$ with $\dim M_p \neq 0$ and compute a maximal interval $I \in \mathcal{I}(M)$ containing $p$. Since $M$ is interval decomposable, by Propositions 31 and 32 we have that $I \in \text{barc}(M)$ and that there is a summand $N \cong I^{\mu_I}$ of $M$. Consider the quotient module $M' := M/N$. Clearly, this “peeling off” of $N$ reduces the total dimension of the input module. Namely, $\dim M'_p = \begin{cases} \dim M_p - \mu_I, & p \in I \\ \dim M_p, & p \notin I. \end{cases}$

We continue the process by replacing $M$ with $M'$ until there is no point $p \in P$ with $\dim M_p \neq 0$ (note that $M'$ is interval decomposable by Proposition 4). Since $\dim M := \sum_{p \in P} \dim M_p$ is finite, this process terminates in finitely many steps. By Propositions 4 and 32, the outcome of `TrueInterval` is a list of all intervals in $\text{barc}(M)$ with accurate multiplicities:

Proposition 33. Assume that $M_F$ is interval decomposable. Let $I_i$, $i = 1, \ldots, k$ be the intervals computed by `TrueInterval`. For each $i = 1, \ldots, k$, let $\mu_{I_i} := \text{rk}_q(M_F)(I_i)$. Then, we have $M_F \cong \bigoplus_{i=1}^k I_i^{\mu_{I_i}}$.

Next, we describe an algorithm `Interval` that simulates `TrueInterval` while avoiding explicit quotienting of $M_F$ by its summands.

We associate a number $d(p)$ and a list `list(p)` of identifiers of intervals $I \subseteq P$ to each point $p \in P$. The number $d(p)$ equals the original dimension of $(M_F)_p$ minus the number of intervals peeled off so far (counted with their multiplicities) which contained $p$. It is initialized to $\dim(M_F)_p$. Each time we compute a maximal interval $I \in \mathcal{I}(M_F)$ with multiplicity $\mu_I$ that contains $p$, we update $d(p) := d(p) - \mu_I$ keeping track of how many more intervals containing $p$ would `TrueInterval` still be peeling off.

With each interval $I$ that is output, we associate an identifier `id(I)`. The variable `list(p)` maintains the set of identifiers of the intervals containing $p$ that have been output so far. While searching for a maximal interval $I$, we maintain a variable `list` for $I$ that contains the set of identifiers common to all points in $I$. Initializing `list` with `list(p)` of the initial point $p$, we update it as we explore expanding $I$. Every time we augment $I$ with a new point $q$, we update `list` by taking its intersection with the set of identifiers `list(q)` associated with $q$.

We assume a routine `Count` that takes a list as input and gives the total number of intervals counted with their multiplicities whose identifiers are in the list. This means that if $\text{list} = \{\text{id}(I_1), \ldots, \text{id}(I_k)\}$, then `Count(list)` returns the number $c := \sum \mu_{I_1} + \cdots + \mu_{I_k}$.

Notice that, while searching for a maximal interval starting from a point, we keep considering the original given module $M_F$ since we do not implement the true “peeling” (i.e., quotient $M_F$ by a submodule). However, we modify the condition for checking the maximality of an interval $I$. We check whether $\text{rk}_q(M_F)(I) > c$, that is, whether the generalized rank of $M_F$ over $I$ is larger than the total number of intervals containing $I$ that would have been peeled off so far by `TrueInterval`. This idea is implemented in the following algorithm.
\section*{Algorithm 2} \textsc{Interval} $(\mathcal{F}, P)$.

\\- Step 1. Call \textsc{Dim}$(\mathcal{F}, P)$ and set $d(p) := \dim(M_{\mathcal{F}})_p$; list$(p) := \emptyset$ for every $p \in P$
\\- Step 2. While there exists a $p \in P$ with $d(p) > 0$ do
  \hspace{1em} Step 2.1 Let $I := \{p\}$; list := list$(p)$; unmark every $q \in P$
  \hspace{2em} Step 2.2 If there exists unmarked $q \in \text{nd}(I)$ then
  \hspace{3em} i. \templist := list $\cap$ list$(q)$; \textit{c} := \textit{Count}(\templist)
  \hspace{3em} ii. If $r_k(M_{\mathcal{F}})(I \cup \{q\}) > c$ then\textsuperscript{5} mark $q$; set $I := I \cup \{q\}$; list := list $\cap$ list$(q)$
  \hspace{3em} iii. go to Step 2.2
  \hspace{1em} Step 2.3 Output $I$ with multiplicity $\mu_I := r_k(M_{\mathcal{F}})(I) - c$
  \hspace{1em} Step 2.4 For every $q \in I$ set $d(q) := d(q) - \mu_I$ and list$(q) := \text{list}(q) \cup \{\text{id}(I)\}$

The output of \textsc{Interval} can be succinctly described as:
\textbf{Output:} $\{(I_i, \mu_{I_i}) : i = 1, \ldots, k\}$ where $I_i \in \text{Int}(P)$ and $\mu_i$ is a positive integer for each $i$.

\textbf{Remark 34.} For each $p \in P$, dim $M_p$ coincides with $\sum_{I_i \ni p} \mu_i$.

We will show that if $M_{\mathcal{F}}$ is interval decomposable, then the output of \textsc{Interval} coincides with the barcode of $M_{\mathcal{F}}$ (Propositions 33 and 37).

\textbf{Example 35 (Interval with interval decomposable input).} Suppose that $M_{\mathcal{F}} \cong I_{I_1} \oplus I_{I_2} \oplus I_{I_3}$, as depicted in Figure 3 (A). The algorithm \textsc{Interval} yields $\{(I_1, 1), (I_2, 1), (I_3, 1)\}$. In particular, since $I_1 \supset I_2 \supset I_3$, \textsc{Interval} outputs $(I_1, 1)$, $(I_2, 1)$, and $(I_3, 1)$ in order, as depicted in Figure 4 (A) (details in the full version).

\textbf{Example 36 (Interval with non-interval-decomposable input).} Suppose that $N := M_{\mathcal{F}} \cong N' \oplus I_{I_2}$ as depicted in Figure 3 (B). $N'$ is an indecomposable module that is not an interval module. One possible final output of \textsc{Interval} is $\{(J_1, 1), (J_2, 1), (J_3, 1)\}$ as depicted in Figure 4 (B). Note however that, depending on the choices of $p$ in Step 2 and the neighbors $q$ in Step 2.2, the final outcome can be different (details in the full version).

\textbf{Proposition 37.} If $M_{\mathcal{F}}$ is interval decomposable, \textsc{Interval}\textsc{(}$\mathcal{F}, P$\textsc{)} computes an interval in $\text{barc}(M_{\mathcal{F}})$ if and only if \textsc{TrueInterval}\textsc{(}$\mathcal{F}, P$\textsc{)} computes it with the same multiplicity.

\textbf{Proof.} ("if"): We induct on the list of intervals in the order they are computed by \textsc{TrueInterval}. We prove two claims by induction: (i) \textsc{TrueInterval} can be run to explore the points in $P$ in the same order as \textsc{Interval} while searching for maximal intervals, (ii) if $I_i$, $i = 1, \ldots, k$, are the intervals computed by \textsc{TrueInterval} with this chosen order, then \textsc{Interval} also outputs these intervals with the same multiplicities. Clearly, for $i = 1$, \textsc{Interval} computes the maximal interval on the same input module $M_{\mathcal{F}}$ as \textsc{TrueInterval} does. So, clearly, \textsc{TrueInterval} can be made to explore $P$ as \textsc{Interval} does and hence their outputs are the same. Assume inductively that the hypotheses hold for $i \geq 1$. Then, \textsc{TrueInterval} operates next on the module $M_{i+1} := M_{\mathcal{F}}/(\sum_{I_i}^{\oplus} I_i)$ (here each $\sum_{I_i}^{\oplus}$ stands for a summand of $M_{\mathcal{F}}$ that is isomorphic to $I_i$ by Proposition 32). We let \textsc{TrueInterval} explore $P$ in the same way as \textsc{Interval} does. This is always possible because the outcome of the test for exploration remains the same in both cases as we argue.

\textsuperscript{5} to check $r_k(M_{\mathcal{F}})(I \cup \{q\}) > c$, we invoke Theorem 24 and run the zigzag persistence algorithm described beneath Remark 25. For efficiency, one can use zigzag update algorithm in [17].
\[ M \cong \begin{array}{c|c|c}
\text{F} & \text{F} & \text{F} \\
\text{F} & \oplus & \text{0} \\
\text{0} & \text{F} & \text{0} \\
\hline I_1 & I_2 & I_3 \\
\end{array} \]

\[ N \cong \begin{array}{c|c|c}
\text{F} & \text{F} & \text{F} \\
\text{F} & \oplus & \text{0} \\
\text{0} & \text{F} & \text{0} \\
\hline N' & I_2 & \text{F} \\
\end{array} \]

**Figure 3** Modules \( M, N : \{1, 2, 3\} \times \{1, 2\} \to \text{vec} \). \( M \) is interval decomposable, but \( N \) is not.

The variable \( d(p) \) at this point has the value \( \dim(M_{i+1})_p \) and thus both \text{TrueInterval} and \text{Interval} can start exploring from the point \( p \) if \( d(p) > 0 \). So, we let \text{TrueInterval} compute the next maximal interval \( I_{i+1} \) starting from the point \( p \) if \text{Interval} starts from \( p \).

Now, when \text{Interval} tests for a point \( q \) to expand the interval \( I \), we claim that the result would be the same if \text{TrueInterval} tested for \( q \). First of all, the condition whether \( I \cup \{q\} \) is an interval or not does not depend on which algorithm we are executing. Second, the list supplied to \text{Count} in Step 2.2 (i) exactly equals the list of intervals containing \( I \cup \{q\} \) that \text{Interval} has already output. By the inductive hypothesis, this list is exactly equal to the list of intervals that \text{TrueInterval} had already “peeled off.” Therefore, the test \( r_k(M_F)(I \cup \{q\}) > c \) that \text{Interval} performs in Step 2.2 (ii) is exactly the same as the test \( r_k(M_{i+1})(I \cup \{q\}) > 0 \) that \text{TrueInterval} would have performed for the module \( M_{i+1} \). This establishes that \text{Interval} computes the same interval \( I_{i+1} \) with the same multiplicity as \text{TrueInterval} would have computed on \( M_{i+1} \) using the same order of exploration as the inductive hypothesis claims.

("only if"): See the full version.
Proposition 38. \( \text{Interval}(\mathcal{F}, P) \) runs in \( O(t^{\omega+2}) \) time (proof in the full version).

4.3 Interval decomposability

Setup 3 still applies in §4.3. We consider the following problem.

Problem III. Determine whether the module \( M_{\mathcal{F}} \) is interval decomposable or not.

If the input module \( M_{\mathcal{F}} \) is interval decomposable, then the algorithm \( \text{Interval} \) computes all intervals in the barcode. However, if the module \( M_{\mathcal{F}} \) is not interval decomposable, then the algorithm is not guaranteed to output all interval summands. We show that \( \text{Interval} \) still can be used to solve Problem III. For this we test whether each of the output intervals \( I \) with multiplicity \( \mu_I \) indeed supports a summand \( N \sim I \mu_I I \) of \( M_{\mathcal{F}} \).

To do this we run Algorithm 3 in Asashiba et al. [1] for each of the output intervals of \( \text{Interval} \). Call this algorithm \( \text{TestInterval} \) which with an input interval \( I \), returns \( \mu_I > 0 \) if the module \( I \mu_I I \) is a summand of \( M_{\mathcal{F}} \) and 0 otherwise.

For each of the intervals \( I \) with multiplicity \( \mu_I \) returned by \( \text{Interval}(\mathcal{F}, P) \) we test whether \( \text{TestInterval}(I) \) returns a non-zero \( \mu_I \). The first time the test fails, we declare that \( M_{\mathcal{F}} \) is not interval decomposable. This gives us a polynomial time algorithm (with complexity \( O(t^{3\omega+2}) \)) to test whether a module induced by a given bifiltration is interval decomposable or not. It is a substantial improvement over the result of Asashiba et al. [1] who gave an algorithm for tackling the same problem. Their algorithm cleverly enumerates the intervals in the poset to test, but still tests exponentially many of them and hence may run in time that is exponential in \( t \). Because of our algorithm \( \text{Interval} \), we can do the same test but only on polynomially many intervals.

Algorithm 3 \( \text{IsIntervalDecomp}(\mathcal{F}, P) \)

1. \( \mathcal{I} = \{(I_i, \mu_{I_i})\} \leftarrow \text{Interval}(\mathcal{F}, P) \)
2. For every \( I_i \in \mathcal{I} \) do
   2.1 \( \mu \leftarrow \text{TestInterval}(M_{\mathcal{F}}, I_i) \)
   2.2 If \( \mu \neq \mu_{I_i} \) then output false; quit
3. output true

Proposition 39. \( \text{IsIntervalDecomp}(\mathcal{F}, P) \) returns true if and only if \( M_{\mathcal{F}} \) is interval decomposable. It takes \( O(t^{3\omega+2}) \) time.

Proof. By the contrapositive of Proposition 33, if for any of the computed interval(s) \( I_i, i = 1, \ldots, k \) by \( \text{Interval} \), \( \bigoplus_{i=1}^{k} I_{I_i}^{\mu_{I_i}} \) is not a summand of \( M_{\mathcal{F}} \), then \( M_{\mathcal{F}} \) is not interval decomposable. On the other hand, if every such interval module is a summand of \( M_{\mathcal{F}} \), then we have that \( M_{\mathcal{F}} \cong \bigoplus_{i=1}^{k} I_{I_i}^{\mu_{I_i}} \) because \( \dim(M_{\mathcal{F}})_p = \sum_{i=1}^{k} \dim(I_{I_i}^{\mu_{I_i}})_p \) for every \( p \in P \).

Time complexity : By Proposition 38, Step 1 runs in time \( O(t^{\omega+2}) \). We claim that \( \dim(M_{\mathcal{F}}) = O(t^{2}) \) (see Proof of Proposition 38 in the full version). Therefore, \( \text{Interval} \) returns at most \( O(t^{2}) \) intervals. According to the analysis in Asashiba et al. [1], each test in Step 2.1 takes \( O((\dim M_{\mathcal{F}})^{\omega} + t^{\omega}) = O(t^{3\omega}) \) time and thus \( O(t^{3\omega+2}) \) in total over all \( O(t^{2}) \) tests which dominates the time complexity of \( \text{IsIntervalDecomp} \).
5 Discussion

The algorithm INTERVAL produces all intervals of an input interval decomposable module. What happens if the input module is not interval decomposable? We can show that the algorithm still produces intervals each supporting a submodule of an indecomposable of the input module (Figure 4), see [18] for details. Some other open questions that follow are: (i) Can we generalize Theorem 24 to $d$-parameter persistent homology for $d > 2$? (ii) Can the complexity of the algorithms be improved? (iii) In particular, can we improve the interval testing algorithm of Asashiba et al.?
