The tree-level two-point amplitudes for the transitions $jf \rightarrow j'f'$, where $f$ is a fermion and $j$ is a generalized current, in a constant uniform magnetic field of an arbitrary strength and in charged fermion plasma, for the $jff$ interaction vertices of the scalar, pseudoscalar, vector and axial-vector types have been calculated. The generalized current $j$ could mean the field operator of a boson, or a current consisting of fermions, e.g. the neutrino current. The particular cases of a very strong magnetic field, and of the coherent scattering off the real fermions without change of their states (the “forward” scattering) have been analysed. The contribution of the neutrino photoproduction process, $\gamma e \rightarrow e\nu\bar{\nu}$, to the neutrino emissivity has been calculated with taking account of a possible resonance on the virtual electron.

Keywords: Charged fermion plasma; magnetic field; Landau levels; astrophysics.

1. Introduction

Nowadays, there exists rather keen interest to astrophysical objects with the scale of the magnetic field strength near the critical value of $B_c = m_e^2/e \simeq 4.41 \times 10^{13}$ G. This group of objects includes the radio pulsars and the so-called magnetars, which are the neutron stars featuring the magnetic field strengths from $10^{12}$ G (radio pulsars) to $4 \times 10^{14}$ G (magnetars), see Ref. 1 and the papers cited therein. The spectra analysis of these objects also provides an evidence for the presence of electron-positron plasma in the radio pulsar and magnetar environment, with the minimum magnetospheric plasma density being of the order of the Goldreich-Julian density:

$$n_{GJ} \simeq 3 \times 10^{13} \text{ cm}^{-3} \left( \frac{B}{100B_c} \right) \left( \frac{10^8}{P} \right),$$

where $n_{GJ}$ is the Goldreich-Julian density, $B$ is the magnetic field strength, and $P$ is the pulsar period.

We use natural units $c = \hbar = k_B = 1$, $m_e$ is the electron mass, and $e$ is the elementary charge, $m_f$ and $e_f$ are the fermion mass and the fermion charge.
where $P$ is the rotational period. It is well-known that strong magnetic field and/or plasma could have an essential influence on various quantum processes because the external active medium catalyses the processes, by changing their kinematics and inducing new interactions. Therefore, the effects of magnetized plasma on microscopic physics should be incorporated in the magnetosphere models of strongly magnetized neutron stars. In the present paper we consider the two-point processes, because such reactions can have possible resonant behavior, and therefore they could be very interesting for astrophysical applications.

The investigation of the two-point processes in an external active medium (electromagnetic field and/or plasma) has a rather long history. The most general expression for a two-vertex loop amplitude of the form $j \to \bar{f} f \to j'$ in a pure constant uniform magnetic field and in a crossed field was obtained previously in Ref. 8, where all possible combinations of scalar, pseudoscalar, vector, and axial-vector interactions of the generalized currents $j$ and $j'$ with fermions were considered. The generalized current $j$ could mean the field operator of a boson, or a current consisting of fermions, e.g. the neutrino current.

The typical example of a tree-level process with two vector vertices in the presence of magnetized plasma is the Compton scattering, $\gamma e \to \gamma e$, as a possible channel of the radiation spectra formation. In this case, both generalized currents $j$ and $j'$ mean the photon field operators. This process was studied in a number of papers, see e.g. Refs. 9–15, but the results were presented there in the form without taking account of the photon dispersion properties. In Ref. 16 this neglect was corrected. The expression for the Compton scattering amplitude, with the initial and final electrons being on the lowest Landau level was presented in Ref. 16 in the explicit Lorentz invariant form. The other example of the Compton like process with the vector and axial-vector vertices, the photon transition into the neutrino pair in the presence of magnetized plasma, $\gamma e \to \nu \bar{\nu}$, was studied in Ref. 17. In this case, in our terms, the initial generalized current $j$ means the photon field operator, while the final generalized current $j'$ means the neutrino current. The local limit of the weak interaction is supposed to be valid. One of our goals in this paper is to improve the approach of Ref. 17 in order to present the results in a manifestly covariant form. Additionally, as we believe, our results would be better applicable for an analysis of the other photon-fermion scattering processes with the production of exotic particles, such as axion, neutralino, etc.

Thus, we consider the tree-level two-point amplitude for the transition of the type $j f \to j' f'$ with the intermediate virtual fermion state. The analysis is performed in a constant uniform magnetic field and charged fermion plasma, for different combinations of the vertices that were used in Ref. 8. Particularly, we generalize the results obtained in Ref. 8 to the case of magnetized plasma, since such a situation looks the most realistic for astrophysical objects. Such a generalization was performed in part in Ref. 18 for the case of the photon polarization operator in a magnetized electron-positron plasma.
The paper is organized as follows. In Sec. 2, we calculate the scattering amplitudes for different spin states of the initial and final fermions. We present here only the amplitudes for the case when both vertices are of the pseudoscalar type. The total set of the amplitudes for the \( jff \) interaction vertices of the scalar, pseudoscalar, vector and axial-vector types, in a constant uniform magnetic field of an arbitrary strength and in charged fermion plasma can be found in the extended paper. All the amplitudes are presented in the explicit Lorentz and gauge invariant forms. The application of the obtained results to the calculation of the neutrino photoproduction process amplitude and other characteristics in the resonant case is given in Sec. 3. Final comments and discussion of the obtained results and possible astrophysical applications are given in Sec. 4. In Appendix A, we present the fermion wave functions used in our analysis, namely, the solutions of the Dirac equation in external magnetic field, being the eigenfunctions of the magnetic moment operator. In the next two Appendices, we present the expressions for the amplitudes in the special cases where they can be essentially simplified. In Appendix B, we consider the particular case, when the initial and final fermions occupy the ground Landau level (the strong field limit), for all types of the \( jff \) interaction vertices. A coherent scattering of neutral particles off the real fermions without change of their states (the “forward” scattering) is analysed in Appendix C.

2. The set of expressions for the amplitudes

The generalized amplitude of the transition \( jf \rightarrow j'f' \) will be analyzed by using the effective Lagrangian for the interaction of a generalized current \( j \) with fermions in the form

\[
\mathcal{L}(X) = \sum_k g_k [\bar{\Psi}_f(X) \Gamma_k \Psi_f(X)] j_k(X),
\]

where the generalized index \( k = S, P, V, A \) numbers the matrices \( \Gamma_k \): \( \Gamma_S = 1 \), \( \Gamma_P = \gamma_5 \), \( \Gamma_V = \gamma_\nu \), \( \Gamma_A = \gamma_\nu \gamma_5 \); \( j_k(X) \) are the generalized currents (\( j_S, j_P, j_\nu \) or \( j_A \)) or the field operators of single particles, e.g. of the photon or axion, see below, \( g_k \) are the corresponding coupling constants, and \( \Psi_f(X) \) are the fermion wave functions.

Indeed, using the Lagrangian (2), one can describe a large class of interactions. For example, it may be:

i) the Lagrangian of the electromagnetic interaction, when \( k = V \), \( g_V = -e_f \), \( \Gamma_V j_V = \gamma_\mu A_\mu \), \( A_\mu \) is the four-potential of the quantized electromagnetic field:

\[
\mathcal{L}(X) = -e_f [\bar{\Psi}_f(X) \gamma_\mu A_\mu(X) \Psi_f(X)];
\]

ii) the Lagrangian of the fermion-axion interaction, when \( k = A \), \( g_A = C_f/(2f_a) \), \( \Gamma_A j_A = \gamma_\mu \gamma_5 \partial_\mu a(X) \), \( a(X) \) is the quantized axion field, \( f_a \) is the Peccei-Quinn symmetry violation scale, \( C_f \) is the model dependent factor of order unity:

\[
\mathcal{L}(X) = \frac{C_f}{2f_a} [\bar{\Psi}_f(X) \gamma_\mu \gamma_5 \Psi_f(X)] \partial_\mu a(X),
\]
iii) The effective local Lagrangian of the four-fermion weak interaction, when $k = V$, $g_V = G_F C_V / \sqrt{2}$ and $k = A$, $g_A = -G_F C_A / \sqrt{2}$:

$$\mathcal{L}(X) = \frac{G_F}{\sqrt{2}} \left[ \bar{\Psi}_f(X) \gamma_\alpha (C_V - C_A \gamma_5) \Psi_f(X) \right] J_\alpha(X),$$

(5)

where $J_\alpha(X) = \bar{\nu}(X) \gamma_\alpha (1 - \gamma_5) \nu(X)$ is the current of left-handed neutrinos; $C_V = \pm 1/2 + 2 \sin^2 \theta_W$, $C_A = \pm 1/2$, and $\theta_W$ is the Weinberg angle. Here, the upper sign corresponds to neutrinos of the same flavor $f$ ($\nu = \nu_f$), when there is an exchange reaction both of $W$ and $Z$ bosons. The lower sign corresponds to the case of another neutrino flavors ($\nu \neq \nu_f$), when there is only $Z$ boson exchange. The conditions of applicability of the effective Lagrangian (5) should be specified. First, it is the condition of relatively small momentum transfers, $|q^2| \ll m_W^2$, where $m_W$ is the $W$ boson mass. And second, the condition that additionally arises in an external magnetic field, is $eB \ll m_W^2$. We will consider physical situations where both of these conditions are satisfied.

In a general case with the Lagrangian (2), the $S$-matrix element in the tree approximation is described by the Feynman diagrams shown in Fig. 1 and has the form

$$S_{j\Gamma_k}' = -g_k g_{k'} \int d^4X d^4Y \langle j_k(X) j_{k'}(Y) \rangle \left[ \bar{\Psi}_{p',\ell'}(Y) \Gamma_{k'} \tilde{S}(Y,X) \Gamma_k \Psi_{p,\ell}(X) \right]$$

(6)

$$+ (j_k, \Gamma_k \leftrightarrow j_{k'}, \Gamma_{k'}).$$

Here, $p^\mu = (E, \mathbf{p})$ and $p'^\mu = (E', \mathbf{p}')$ are the four-momenta of the initial and final fermions correspondingly, $X^\mu = (X_0, X_1, X_2, X_3)$, the currents between the angle brackets mean the matrix element between the corresponding initial and final states, $\Psi_{p,\ell}(X)$ are the fermion wave functions in the presence of external magnetic field, where the subscript describes a state with definite components of the four-momentum $p$ and with the Landau level number $\ell$, while the superscript describes the spin state $s$.

There exist several descriptions of the procedure of obtaining the fermion wave functions in the presence of an external magnetic field by solving the Dirac equation, see e.g. Refs. 20–26 and also Refs. 5, 6. In the most cases, the solutions are presented in the form with the upper two components of the bispinor corresponding to the
fermion states with the spin projections $1/2$ and $-1/2$ on the magnetic field direction. Here, we have found it more convenient to use another representation of the fermion wave functions, being the eigenstates of the magnetic moment operator. Some details on these wave functions are presented in Appendix A.

The currents $j_k$ in Eq. (6) can be expressed through the amplitudes in the momentum space:

$$j_k(X) = \frac{e^{-i(qX)}}{\sqrt{2q_0}} j_k(q).$$

We use the fermion propagator in the form of the sum over the Landau levels:

$$S(X, X') = \sum_{n=0}^{\infty} S_n(X, X'),$$

$$S_n(X, X') = \frac{i}{2n!} \sqrt{\frac{\beta}{\pi}} \exp \left( -\beta \frac{X_1^2 + X_1'^2}{2} \right)$$

$$\times \int \frac{dp_0 dp_y dp_z}{(2\pi)^3} \frac{e^{-i(p(X-X'))_\parallel}}{p^2 - m^2 - 2\beta n + i\varepsilon}$$

$$\times \exp \left\{ -\frac{p_y^2}{\beta} - p_y [X_1 + X_1' - i(X_2 - X_2')] \right\}$$

$$\times \left\{ [(p\gamma)_n + m] [I_\perp H_n(\xi) H_n(\xi') + I_\parallel 2n H_{n-1}(\xi) H_{n-1}(\xi')] + i2n \sqrt{\beta} \gamma^1 [I_\perp H_{n-1}(\xi) H_n(\xi') - I_\parallel H_n(\xi) H_{n-1}(\xi')] \right\},$$

where $\xi$ is defined by Eq. (A.14) and $\xi'$ is obtained from $\xi$ by substituting $X_1 \to X_1'$.

Hereafter we use the following notations: four-vectors with the indices $\perp$ and $\parallel$ belong to the Euclidean $\{1, 2\}$ subspace and the Minkowski $\{0, 3\}$ subspace correspondingly. Then for arbitrary 4-vectors $A_\mu, B_\mu$ one has

$$A_\mu^\perp = (0, A_1, A_2, 0), \quad A_\mu^\parallel = (A_0, 0, 0, A_3),$$

$$(AB)_\perp = (AAB) = A_1 B_1 + A_2 B_2,$$

$$(AB)_\parallel = (A\bar{A}B) = A_0 B_0 - A_3 B_3,$$

where the matrices $A_\mu^\nu = (\varphi_\phi)_{\mu\nu}$, $\bar{A}_\mu^\nu = (\bar{\varphi}_\phi)_{\mu\nu}$ are constructed with the dimensionless tensor of the external magnetic field, $\varphi_\mu = F_\mu^\nu / B$, and the dual tensor, $\bar{\varphi}_\mu = \frac{1}{2} \varepsilon_{\mu\nu\rho\sigma} \varphi^{\rho\sigma}$. The matrices $A_\mu^\nu$ and $\bar{A}_\mu^\nu$ are connected by the relation $\bar{A}_\mu^\nu - A_\mu^\nu = \delta_\mu^\nu = \text{diag}(1, -1, -1, -1)$, and play the roles of the metric tensors in the perpendicular ($\perp$) and the parallel ($\parallel$) subspaces respectively.
After integration in Eq. (6) over $d^4X$ and $d^4Y$ we obtain

$$S_{k'k}^{s's} = \frac{i(2\pi)^3\delta^{(3)}(P - p' - q')}{\sqrt{2q_0V2q_0V2E_pL_yL_z2E'_pL_yL_z}} M_{k'k}^{s's},$$

where $\delta^{(3)}(P - p' - q') = \delta(P_0 - E'_p - q'_0)\delta(P_y - p'_y - q'_y)\delta(P_z - p'_z - q'_z)$, $P_\alpha = (p + q)_\alpha$, $\alpha = 0, 2, 3$, and the partial amplitudes $M_{k'k}^{s's}$ can be presented in the following form:

$$M_{k'k}^{s's} = \frac{-\exp [-i\theta]}{2 \sqrt{M_0 M'_0 (M_0 + m_f)(M'_0 + m_f)}}$$

$$\times \left\{ \exp \left[ \frac{i(q_0q'_0)}{2\beta} \right] \left[ q_y + iq_x \right]^{-\ell^{'+}} \left[ q'_y - iq'_x \right]^{-\ell'} \times \sum_{n=0}^{\infty} \left( \frac{(q_0q'_0) - i(q_0q'_0)}{q^2 q'^2} \right)^n \frac{R_{k'k}^{(1)s's}}{P_0^2 - m_0^2 - 2\beta n} \right\} + (-1)^{\ell^{'+}} \exp \left[ \frac{i(q_0q'_0)}{2\beta} \right] \left[ q'_y + iq'_x \right]^{-\ell} \left[ q_y - iq_x \right]^{-\ell'}$$

$$\times \sum_{n=0}^{\infty} \left( \frac{(q_0q'_0) + i(q_0q'_0)}{q^2 q'^2} \right)^n \frac{R_{k'k}^{(2)s's}}{P_0^2 - m_0^2 - 2\beta n},$$

where $\theta = (q_x - q'_x)(p_y + p'_y)/(2\beta)$ is the general phase for both diagrams in Fig. 1.

$P'_\alpha = (p - q'_x)_\alpha$.

The main part of the problem is to calculate the values $R_{k'k}^{(1,2)s's}$ which are expressed via the following Lorentz covariants in the $\{0, 3\}$-subspace

$$K_{1\alpha} = \sqrt{\frac{2}{(p\Lambda p') + M_0 M'_0}} \left\{ M_0(\bar{\Lambda}p')_\alpha + M'_0(\bar{\Lambda}p)_\alpha \right\},$$

$$K_{2\alpha} = \sqrt{\frac{2}{(p\bar{\Lambda}p') + M_0 M'_0}} \left\{ M_0(\bar{\Lambda}p')_\alpha + M'_0(\bar{\Lambda}p)_\alpha \right\},$$

$$K_3 = \sqrt{2 \left[ (p\bar{\Lambda}p') + M_0 M'_0 \right]},$$

$$K_4 = -\sqrt{\frac{2}{(p\bar{\Lambda}p') + M_0 M'_0}} (p\bar{\varphi}p').$$

The following integrals appear in the calculations:

$$\frac{1}{\sqrt{\pi}} \int dZ e^{-Z^2} H_n \left( Z + \frac{q_y + iq_x}{2\sqrt{\beta}} \right) H_{\ell}\left( Z - \frac{q_y - iq_x}{2\sqrt{\beta}} \right)$$

$$= 2^{(n+\ell)/2} \sqrt{n!} \sqrt{\beta} \left[ \frac{q_y + i q_x}{\sqrt{q^2_x}} \right]^{n-\ell} \left[ e^{q^2_x/(4\beta)} I_n(\frac{q^2_y}{2\beta}) \right],$$

expressed via the following Lorentz covariants in the $\{0, 3\}$-subspace.
where, for $n \geq \ell$

\[ I_{n,\ell}(x) = \sqrt{\frac{\ell!}{n!}} e^{-x/2} x^{(n-\ell)/2} L_{\ell}^{n-\ell}(x), \quad I_{\ell,n}(x) = (-1)^{n-\ell} I_{n,\ell}(x), \] (17)

and $L_{\ell}^{n}(x)$ are the generalized Laguerre polynomials.\(^{22}\)

Below, the results are presented for the values $\mathcal{R}_{k'k}^{(1,2)}$'s in the case when both vertices are of the pseudoscalar type, $k = k' = P$. The total set of the values $\mathcal{R}_{k'k}^{(1,2)}$'s for the $jff$ interaction vertices of the scalar, pseudoscalar, vector and axial-vector types, in a constant uniform magnetic field of an arbitrary strength and in charged fermion plasma is presented in the extended paper.\(^{19}\)

Hereafter we use the following definitions: $\mathcal{I}_{n,\ell} = \mathcal{I}_{n,\ell} \left( q_{+}^2/(2\beta) \right)$ and $\mathcal{I}_{n,e} = \mathcal{I}_{n,e} \left( q_{+}^2/(2\beta) \right)$. For definiteness, we further consider the fermion with a negative charge, $e_f = -|e_f|$. In the case when $j$ and $j'$ are the pseudoscalar currents ($k = k' = P$) we obtain

\[ \mathcal{R}_{PP}^{(1)++} = -g_{P}g'_{P}j_{P}j'_{P} \left\{ 2\beta \sqrt{\ell\ell'} \left( [K_1 P] + m_f K_3 \right) \mathcal{I}_{n,e} \mathcal{I}_{n,\ell} \right. \]
\[ + (M_\ell + m_f)(M_{\ell'} + m_f) \left[ (K_1 P) - m_f K_3 \right] \mathcal{I}_{n-1,\ell'-1} \mathcal{I}_{n-1,\ell-1} \]
\[ \left. - 2\beta \sqrt{n} K_3 \left[ \sqrt{\ell}(M_\ell + m_f) \mathcal{I}_{n-1,\ell'-1} \mathcal{I}_{n,\ell} + \sqrt{\ell'}(M_{\ell'} + m_f) \mathcal{I}_{n,\ell} \mathcal{I}_{n-1,\ell'-1} \right] \right\}; \]

\[ \mathcal{R}_{PP}^{(1)+-} = -ig_{P}g'_{P}j_{P}j'_{P} \left\{ 2\beta \sqrt{\ell\ell'} \left( M_\ell + m_f \right) \left[ (K_2 P) + m_f K_4 \right] \mathcal{I}_{n,e} \mathcal{I}_{n,\ell} \right. \]
\[ - \sqrt{2\beta \ell} (M_{\ell'} + m_f) \left[ (K_2 P) - m_f K_4 \right] \mathcal{I}_{n-1,\ell'-1} \mathcal{I}_{n-1,\ell-1} \]
\[ \left. - \sqrt{2\beta n} K_4 \left[ (M_\ell + m_f)(M_{\ell'} + m_f) \mathcal{I}_{n-1,\ell'-1} \mathcal{I}_{n,\ell} - 2\beta \sqrt{\ell\ell'} \mathcal{I}_{n,\ell} \mathcal{I}_{n-1,\ell'-1} \right] \right\}; \]

\[ \mathcal{R}_{PP}^{(1)-+} = ig_{P}g'_{P}j_{P}j'_{P} \left\{ \sqrt{2\beta \ell} (M_{\ell'} + m_f) \left[ (K_2 P) - m_f K_4 \right] \mathcal{I}_{n,e} \mathcal{I}_{n,\ell} \right. \]
\[ - \sqrt{2\beta \ell'} (M_\ell + m_f) \left[ (K_2 P) + m_f K_4 \right] \mathcal{I}_{n-1,\ell'-1} \mathcal{I}_{n-1,\ell-1} \]
\[ \left. - \sqrt{2\beta n} K_4 \left[ 2\beta \sqrt{\ell\ell'} \mathcal{I}_{n-1,\ell'-1} \mathcal{I}_{n,\ell} - (M_\ell + m_f)(M_{\ell'} + m_f) \mathcal{I}_{n,\ell} \mathcal{I}_{n-1,\ell'-1} \right] \right\}; \]

\[ \mathcal{R}_{PP}^{(1)--} = -g_{P}g'_{P}j_{P}j'_{P} \left\{ (M_\ell + m_f)(M_{\ell'} + m_f) \left[ (K_1 P) - m_f K_3 \right] \mathcal{I}_{n,e} \mathcal{I}_{n,\ell} \right. \]
\[ + 2\beta \sqrt{\ell\ell'} \left[ (K_1 P) + m_f K_3 \right] \mathcal{I}_{n-1,\ell'-1} \mathcal{I}_{n-1,\ell-1} \]
\[ \left. - 2\beta \sqrt{n} K_3 \left[ \sqrt{\ell}(M_\ell + m_f) \mathcal{I}_{n-1,\ell'-1} \mathcal{I}_{n,\ell} + \sqrt{\ell'}(M_{\ell'} + m_f) \mathcal{I}_{n,\ell} \mathcal{I}_{n-1,\ell'-1} \right] \right\}. \]
To obtain the contributions $R^{(2)}_{PP}'s$ from the second diagram of Fig. 1, the following replacements should be made in Eqs. (18)—(21): $P_\alpha \rightarrow P'_\alpha$, $I_{m,n} \leftrightarrow I'_{m,n}$.

The results obtained for the case of the magnetic field of an arbitrary strength can be essentially simplified in several special cases. In Appendix B, the set of expressions for the amplitudes in the limit of relatively strong field is presented, where the initial and final fermions are on the ground Landau level, $\ell, \ell' = 0$, but the virtual electron can occupy an arbitrary Landau level, $n \neq 0$.

One more case when the amplitudes can be essentially simplified is the process of a coherent scattering of the generalized current $j$ off the real fermions of magnetized plasma without change of their states (the “forward” scattering). The set of expressions for the amplitudes in this case is presented in Appendix C.

3. Neutrino luminosity

As an illustration of the results obtained, let us construct the amplitude of the neutrino-antineutrino pair photoproduction, $\gamma e \rightarrow e\nu\bar{\nu}$, in a strongly magnetized cold plasma when the temperature $T$ is the smallest parameter of the problem, i.e., $T \ll \mu_e - m_e$ ($\mu_e$ is the chemical potential of the electron gas, $m_e$ is the electron mass) with taking account of a possible resonance on a virtual electron.

At the same time, our main goal is to obtain the expression for the neutrino emissivity caused by the process $\gamma e \rightarrow e\nu\bar{\nu}$. In turn, the neutrino emissivity can be defined as the zero component of the four-vector of the energy-momentum carried away by the neutrino pair due to this process from a unit volume of plasma per unit time. Here, we neglect the inverse effect of the energy and momentum loss on the state of plasma. The neutrino emissivity can be represented in the form:

$$Q_{\gamma e \rightarrow e\nu\bar{\nu}} = \frac{1}{V} \sum_{\ell, \ell' = 0}^{\infty} \iint \frac{d^3k}{(2\pi)^3 2q_0} f_\gamma(q_0) \frac{d^2p}{(2\pi)^2 2E_\ell} f_e(E_\ell) \times$$

$$\times \frac{d^2p'}{(2\pi)^2 2E'_{\ell'}} [1 - f_e(E'_{\ell'})] \frac{d^3p_1}{(2\pi)^3 2\epsilon_1} \frac{d^3p_2}{(2\pi)^3 2\epsilon_2} q'_0 \times$$

$$\times (2\pi)^3 \delta^3(P - p' - q') |\mathcal{M}_{\gamma e \rightarrow e\nu\bar{\nu}}|^2,$$

where $f_\gamma(q_0) = \left[ e^{q_0/T} - 1 \right]^{-1}$ is the equilibrium distribution function of an initial photon with the four-vector $q^\mu = (q_0, \mathbf{k})$; $f_e(E_\ell)$ and $f_e(E'_{\ell'})$ are the equilibrium distribution functions of initial and final electrons, respectively, $f_e(E_\ell) = \left[ e^{(E_\ell - \mu_e)/T} + 1 \right]^{-1}$; $q'_0 = \epsilon_1 + \epsilon_2$ is the neutrino pair energy, $\epsilon_{1,2} = |p_{1,2}|$; $d^2p = dp_y dp_z$; $V = L_xL_yL_z$ is the plasma volume.

In calculating the amplitude $\mathcal{M}_{\gamma e \rightarrow e\nu\bar{\nu}}$ of the process $\gamma e \rightarrow e\nu\bar{\nu}$, we consider the case of relatively small momentum transfers compared with the $W$ boson mass, $|q'^2| \ll m_W^2$. Then the corresponding interaction Lagrangian can be written as
follows, see Eq. (5):

\[ L = \frac{G_F}{\sqrt{2}} \left[ \bar{\Psi} \gamma_\alpha (C_V - C_A \gamma_5) \Psi \right] \left[ \bar{\nu} \gamma_\alpha (1 - \gamma_5) \nu \right] + e (\bar{\Psi} \gamma_\alpha \Psi) A_\alpha, \tag{23} \]

where \( A_\alpha \) is the four-potential of the photon field.

Comparing (23) with the Lagrangian of the general form (2) we find that the amplitude squared of the process \( \gamma e \rightarrow e \nu \bar{\nu} \) can be represented as:

\[ |M_{\gamma e \rightarrow e \nu}^s|^2 = \sum_{s',s} |M_{VV}^{s's} + M_{VA}^{s's}|^2, \tag{24} \]

and in formulas (B.2), (B.17)–(B.20) one should put \( m_f = m_e, g_V = e, \) where \( e > 0 \) is the elementary charge, \( j_\alpha = \epsilon_\alpha \) is the initial photon polarization vector, \( g_V' = G_F C_V / \sqrt{2}, \) \( g_A' = -G_F C_A / \sqrt{2}, \) \( j_{\alpha}' = \bar{\nu} \gamma_\alpha (1 - \gamma_5) \nu. \)

It should be noted that the virtual electron resonance occurs only in the \( s \) channel diagram (the first diagram in Fig. 1). Nevertheless, even with the simplification caused by the resonance behavior, the problem under consideration is still enough cumbersome, because the charged fermions can occupy arbitrary Landau levels. The problem could be significantly simplified in the physical conditions of magnetars. Indeed, in the outer crust of a magnetar, the following hierarchy of parameters should exist: \( eB \gg m_e^2, \mu_e^2, T^2. \) Thus, the electron plasma can be considered as a strongly magnetized one, and under these assumptions one can approximately assume that the initial and the final electrons would occupy the ground Landau level (\( \ell = \ell' = 0 \)), while the virtual electron can occupy an arbitrary Landau level.

In our case, \( s' = s = -1 \) and the amplitude squared (24) takes the form

\[ |M_{\gamma e \rightarrow e \nu}^s|^2 = \sum_{n=1}^{\infty} \left( \frac{q A q'}{q^2 q'^2} \right)^n \frac{\mathcal{R}_n}{P^2 - m_e^2 - 2\beta n} \left( R_{VV}^{(1)} + R_{AV}^{(1)} \right)^2, \tag{25} \]

where

\[ \mathcal{R}_n = \frac{1}{n!} \left( \frac{q^2}{2\beta} \right)^{n/2} \left( \frac{q'^2}{2\beta} \right)^{n/2} \exp \left[ -\frac{q^2 + q'^2}{4\beta} \right] \left( R_{VV}^{(1)} + R_{AV}^{(1)} \right), \tag{26} \]

and the functions \( R_{VV}^{(1)} \) and \( R_{AV}^{(1)} \) are defined by Eqs. (B.17) and (B.19).

To accurately take into account the resonance behavior in the process \( \gamma e \rightarrow e \nu \), it is necessary to calculate radiative corrections to the electron mass, caused by the combined action of a magnetic field and plasma. This calculation is a separate challenge. However, because of the smallness of these corrections, we can approximately replace \( m_e^2 \rightarrow m_e^2 - iP_0 \Gamma_n \) in the denominator of Eq. (25).

As it was already noted, the main contribution to the amplitude arises from the resonance region, so that we can approximately replace the corresponding part of
Eq. (25) by the δ function:

$$|\mathcal{M}_{\gamma e \rightarrow e\nu\bar{\nu}}|^2 \simeq \sum_{n=1}^{\infty} \frac{|\mathcal{R}_n|^2}{(P_1^2 - m_e^2 - 2\beta n)^2 + P_0^2 \Gamma_n^2} \simeq \sum_{n=1}^{\infty} \frac{\pi}{P_0 \Gamma_n} \delta(P_1^2 - m_e^2 - 2\beta n) |\mathcal{R}_n|^2,$$

where \( \Gamma_n \) is the total width of the change of the electron state. This width can be represented in the form:

$$\Gamma_n = \Gamma_{abs}^{\nu} + \Gamma_{cr}^{\nu} \simeq \Gamma_{\epsilon_0 \gamma \rightarrow e_n}^{\nu} \left[ 1 + e^{(E_n'' - \mu_e)/T} \right].$$

Here

$$\Gamma_{\epsilon_0 \gamma \rightarrow e_n}^{\nu} = \frac{1}{2E_n''} \int \frac{d^3k}{2\alpha(2\pi)^3} f_\gamma(q_0) \frac{d^2p}{2E_0(2\pi)^2} f_e(E_0) \times (2\pi)^3 \delta^3(P - p'') |\mathcal{M}_{\epsilon_0 \gamma \rightarrow e_n}^{\nu}|^2$$

is the width of the electron creation in the \( n \)th Landau level.

With taking account of Eq. (28), the amplitude squared of the process \( \gamma e \rightarrow e\nu\bar{\nu} \) takes the form:

$$|\mathcal{M}_{\gamma e \rightarrow e\nu\bar{\nu}}|^2 = \sum_{n=1}^{\infty} \int \frac{d^2p''}{(2\pi)^2} \frac{2E_n''}{2E_n'} \delta^3(P - p'') \frac{|\mathcal{R}_n|^2}{2E_n'} \frac{1}{\Gamma_n}$$

where \( E_n'' = \sqrt{p''^2 + m_e^2 + 2\beta n} \).

On the other hand, in the case of resonance the expression for \(|\mathcal{R}_n|^2\) being averaged over the photon polarizations can be factored in the strong field limit \( \beta \gg m_e^2 \) as follows (see, for example, Ref. 31):

$$|\mathcal{R}_n|^2 = |\mathcal{M}_{\epsilon_0 \gamma \rightarrow e_n}^{\nu}|^2 |\mathcal{M}_{e_n \rightarrow e\nu\bar{\nu}}^{\nu}|^2,$$

where

$$|\mathcal{M}_{\epsilon_0 \gamma \rightarrow e_n}^{\nu}|^2 = \frac{8\pi \alpha}{n!} \exp\left(-\frac{q_0^2}{2\beta}\right) \left(\frac{q_0^2}{2\beta}\right)^n M_n^2(p\tilde{\gamma})$$

$$\times \sum_{\lambda=1}^{3} \left[ |A_1^{(\lambda)}|^2 + |A_2^{(\lambda)} + \sigma A_3^{(\lambda)}|^2 \right]$$

is the amplitude of the absorption of a photon in the process \( e_0\gamma \rightarrow e_n \), when an electron passes from the ground Landau level to a higher Landau level \( n \). The parameter \( \sigma = (p\tilde{\gamma}_q)/(p\tilde{\gamma}_q) = \pm 1 \) determines the direction of the photon propagation.
with respect to the magnetic field direction. \(A_i^{(\lambda)}\) are the expansion coefficients of the photon polarization vector \(\epsilon_\mu^{(\lambda)}\) over the basis of the 4-vectors:

\[
b^{(1)}_\mu = (\varphi q)_\mu, \quad b^{(2)}_\mu = (\varphi q)_\mu, \quad b^{(3)}_\mu = q^2 (\Lambda q)_\mu - q_\mu q_z^2, \quad b^{(4)}_\mu = q_\mu.
\]

(34)

Given the gauge invariance, one has:

\[
\epsilon_\mu^{(\lambda)} = \sum_{i=1}^3 A_i^{(\lambda)} b^{(i)}_\mu.
\]

(35)

Finally, the amplitude squared of the electron transition from the \(n\)th Landau level to the ground level with the creation of the neutrino-antineutrino pair takes the form:

\[
|M_{e_n \rightarrow e_0 \nu \bar{\nu}}|^2 = \frac{G_F^2}{n!} \exp \left( -\frac{q^2}{2\beta} \right) \left( \frac{q^2}{2\beta} \right)^n \frac{M_n^2}{(p')^2 \Lambda^2} \left\{ C_V(p' \Lambda j') - C_A(p' \bar{\nu} j') \right\}^2 \\
+ \left( \frac{j' \Lambda j}{q^2} \right) \left[ C_V(p' \Lambda q') - C_A(p' \bar{\nu} q') \right]^2 - \frac{2 q^2}{q^2} \left[ C_V(p' \Lambda q') - C_A(p' \bar{\nu} q') \right] \\
\cdot \text{Re} \left( (q' \Lambda j') \left[ C_V(p' \Lambda j') - C_A(p' \bar{\nu} j') \right] \right)
\]

(36)

Substituting Eq. (30) into the expression for the luminosity (22), and taking into account Eqs. (29) and (32), we obtain:

\[
Q_{\gamma e_n \rightarrow e_0 \nu \bar{\nu}} = \sum_{n=1}^\infty Q_{e_n \rightarrow e_0 \nu \bar{\nu}},
\]

(37)

where

\[
Q_{e_n \rightarrow e_0 \nu \bar{\nu}} = \frac{1}{L_x} \int \frac{d^2 p''}{(2\pi)^2} f_c(E''') \frac{d^2 p'}{(2\pi)^2} \frac{d^3 p_1}{(2\pi)^3} \frac{d^3 p_2}{(2\pi)^3} \delta^3(p'' - p' - q') |M_{e_n \rightarrow e_0 \nu \bar{\nu}}|^2,
\]

(38)

is the neutrino luminosity due to the process \(e_n \rightarrow e_0 \nu \bar{\nu}\). This result coincides, up to notation, with the result of Ref. [29]

4. Discussion

In this paper, we have calculated the tree-level two-point amplitudes for the transitions \(jf \rightarrow j'f'\) in a constant uniform magnetic field of an arbitrary strength, and in charged fermion plasma, for generalized vertices of the scalar, pseudoscalar, vector and axial vector types. It is remarkable, that all the amplitudes obtained are manifestly Lorentz invariant, due to the choice of the Dirac equation solutions as the eigenfunctions of the covariant operator \(\hat{\mu}_\mu\). In this case, partial contributions to an amplitude from the channels with different fermion polarization states are
calculated separately, by direct multiplication of the bispinors and the Dirac matrices. This approach is an alternative to the method where the amplitudes squared are calculated, with summation over the fermion polarization states, and with using the fermion density matrices, see, e.g. Refs. 32, 33. However, the use of the density matrix in a magnetic field, as is usually done in the absence of a magnetic field, in the case of the two-vertex processes leads to extreme difficulties in analytical calculations.

The set of the amplitudes for the transitions $j_f \rightarrow j'_f$ in a constant uniform magnetic field of an arbitrary strength, and in charged fermion plasma, presented in this paper, can be used as a reference book in the investigations of the quantum processes in external active media. The field effects are taken into account exactly, because exact solutions of the Dirac equation are used. Owing to this, the expression obtained here for the amplitude is quite general; in particular, it can be widely used to analyze various physical phenomena and processes in a magnetic field and in plasma. The amplitudes $M_{SS}$ and $M_{PP}$, which are diagonal in the generalized currents, differ only in factors from the external-medium-induced contributions to the mass operators of the corresponding scalar and pseudoscalar fields. The amplitude $M_{VV}$ defines, for example, the medium-induced part of the photon polarization operator. The amplitudes $M_{VV}$ and $M_{VA}$ describe the process amplitude for the radiative transition of a massless neutrino $\nu \rightarrow \nu \gamma$. Similarly, one can obtain the amplitudes for the axion decay $a \rightarrow \nu \bar{\nu}$ and for axion–photon oscillations by means of the corresponding substitutions.

Furthermore, the results obtained can be used to analyze the reactions with a possible resonance on the virtual electron (see e.g. Ref. 34). It is well known that the processes of this type play an important role in the magnetospheres of isolated neutron stars, providing the production of $e^+ e^-$ plasma.

Although the obtained formulas look quite cumbersome, there are certain areas of their application. We emphasize that these formulas are derived for a general case, namely, for arbitrary values of the magnetic field, therefore, they can recover the results within the limits of weak and superstrong fields. Further, in this general form the formulas definitely may be used for numerical calculations.

Acknowledgments

Appendix A. Solutions of the Dirac equation in an external magnetic field

In this Appendix, we present the fermion wave functions as the solutions of the Dirac equation in the presence of an external magnetic field, and simultaneously as the eigenfunctions of the magnetic moment operator.[22,23]

In Ref. [22] an operator was introduced which was called the generalized spin tensor of the third rank. In modern standard notations, the operator takes the form

\[ F_{\mu\nu\lambda} = -\frac{i}{2} \left( P_{\lambda} \gamma_0 \sigma_{\mu\nu} + \gamma_0 \sigma_{\mu\nu} P_{\lambda} \right), \]  

\[ (A.1) \]

where \( \sigma_{\mu\nu} = (\gamma_\mu \gamma_\nu - \gamma_\nu \gamma_\mu)/2 \), and \( P^\lambda = i\partial^\lambda - ef A^\lambda = (i\partial_0 - ef A_0, -i\nabla - ef A) \) is the generalized four-momentum operator with \( A^\lambda \) being the four-potential of an external magnetic field. Taking the component \( F_{\mu\nu0} \) of the operator \((A.1)\) and taking into account that in the Schrödinger form of the Dirac equation one has \( i\partial_0 = H \), where \( H = \gamma_0 (\gamma P) + mf \gamma_0 + ef A_0 \) is the Dirac Hamiltonian, one can construct the vector operator

\[ \mu_i = -\frac{1}{2} \epsilon_{ijk} F_{jk0}, \]  

\[ (A.2) \]

where \( \epsilon_{ijk} \) is the Levi-Civita symbol. This is the magnetic moment operator[22,23] which can be presented in the form

\[ \mu = mf \Sigma - i\gamma_0 \gamma_5 [\Sigma \times \vec{P}], \]  

\[ (A.3) \]

It is straightforward to show that the components of the operator \((A.3)\) commute with the Hamiltonian, i.e. \( H \) and \( \mu_z \) have common eigenfunctions. In the non-relativistic limit, the operator \((A.3)\) is transformed to the ordinary Pauli magnetic moment operator, thus having an obvious physical interpretation.

It appears to be convenient to use the fermion wave functions as the eigenstates of the operator \( \mu_z \)[24,25]

\[ \mu_z = mf \Sigma z - i\gamma_0 \gamma_5 [\Sigma \times \vec{P}]z, \]  

\[ (A.4) \]

where \( \vec{P} = -i\nabla - ef A \). We take the frame where the field is directed along the \( z \) axis, and the Landau gauge where the four-potential is: \( A^\lambda = (0, 0, xB, 0) \). It is convenient to use the notation \( \beta = |ef|B \), and to introduce the sign of the fermion charge as \( \eta = ef/|ef| \).

Our choice of the Dirac equation solutions as the eigenfunctions of the operator \( \mu_z \) is caused by the following arguments. Calculations of the process widths with two or more vertices in an external magnetic field by the standard method, including the squaring the amplitude with all the Feynman diagrams and with summation.

---

\textsuperscript{1}It should be noted that in Ref. [22] the covariant bilinear forms were constructed of Dirac matrices by inserting them not between bispinors \( \psi \) and \( \psi^\dagger \) as accepted in modern literature[36] but between bispinors \( \psi^\dagger \) and \( \psi \).
or averaging over the fermion polarization states, contain significant computational difficulties. In this case, it is convenient to calculate partial contributions to the amplitude from the channels with different fermion polarization states and for each diagram separately, by direct multiplication of the bispinors and the Dirac matrices. The result, up to a total for both diagrams non-invariant phase, will have an explicit Lorentz invariant structure. On the contrary, the amplitudes obtained with using the solutions for a fixed direction of the spin, do not have Lorentz invariant structure. Only the amplitude squared, summed over the fermion polarization states, is manifestly Lorentz-invariant with respect to a boost along the magnetic field direction.

The fermion wave functions having the form

\[
\Psi_{p,n}^{s}(X) = \frac{e^{-i(E_n x_0 - p_y x_2 - p_z x_3)} U_{n}^{s}(\xi)}{\sqrt{4E_n M_n (E_n + M_n)(M_n + m_f) L_y L_z}},
\]

where

\[
E_n = \sqrt{M_n^2 + p_z^2}, \quad M_n = \sqrt{m_f^2 + 2\beta n},
\]

are the solutions of the equation

\[
\hat{\mu}_z \Psi_{p,n}^{s}(X) = s M_n \Psi_{p,n}^{s}(X), \quad s = \pm 1.
\]

It is convenient to present the bispinors \(U_{n}^{s}(\xi)\) in the form of decomposition over the solutions for negative and positive fermion charge, \(U_{n,\eta}^{s}(\xi)\):

\[
U_{n}^{s}(\xi) = \frac{1 - \eta}{2} U_{n,-}^{s}(\xi) + \frac{1 + \eta}{2} U_{n,+}^{s}(\xi),
\]

where

\[
U_{n,-}^{s}(\xi) = \begin{pmatrix}
-\frac{i\sqrt{2} p_z V_{n-1}(\xi)}{2M_n}
\end{pmatrix},
\]

\[
U_{n,+}^{s}(\xi) = \begin{pmatrix}
\frac{(E_n + M_n)(M_n + m_f)V_{n-1}(\xi)}{2M_n}
\end{pmatrix},
\]

and

\[
U_{n,-}^{s}(\xi) = \begin{pmatrix}
\frac{i\sqrt{2} p_z V_{n}(\xi)}{2M_n}
\end{pmatrix},
\]

\[
U_{n,+}^{s}(\xi) = \begin{pmatrix}
\frac{(E_n + M_n)(M_n + m_f)V_{n}(\xi)}{2M_n}
\end{pmatrix}.
\]
\[ U_{n,+}^- (\xi) = \begin{pmatrix} i\sqrt{2\beta n} p_z V_n (\xi) \\ (E_n + M_n)(M_n + m_f)V_{n-1} (\xi) \\ i\sqrt{2\beta n}(E_n + M_n)V_n (\xi) \\ -p_z(M_n + m_f)V_{n-1} (\xi) \end{pmatrix}, \] (A.11)

\[ U_{n,+}^+ (\xi) = \begin{pmatrix} (E_n + M_n)(M_n + m_f)V_n (\xi) \\ i\sqrt{2\beta n} p_z V_{n-1} (\xi) \\ p_z(M_n + m_f)V_n (\xi) \\ -i\sqrt{2\beta n}(E_n + M_n)V_{n-1} (\xi) \end{pmatrix}, \] (A.12)

\[ V_n (\xi) (n = 0, 1, 2, \ldots) \text{ are the normalized harmonic oscillator functions, which are expressed in terms of the Hermite polynomials } H_n (\xi): \]

\[ V_n (\xi) = \frac{\beta^{1/4} e^{-\xi^2/2}}{\sqrt{2^n n! \sqrt{\pi}}} H_n (\xi), \] (A.13)

\[ \xi = \sqrt{\beta} \left( X_1 - \eta \frac{p_y}{\beta} \right). \] (A.14)

**Appendix B. The set of expressions for the amplitudes for ground Landau Level, \( \ell = \ell' = 0 \)**

In this Appendix, we consider the limit of relatively strong field, where the initial and final fermions are on the ground Landau level, \( \ell, \ell' = 0 \), but the virtual electron can occupy the arbitrary Landau level, \( n \neq 0 \). In this case \( s = s' = -1 \), \( M_e = M_{e'} = m_f \), and

\[ \mathcal{I}_{n,0} (x) = \frac{1}{\sqrt{n!}} e^{-x/2} x^{n/2}, \quad \mathcal{I}_{n-1,0} (x) = \sqrt{\frac{n}{x}} \mathcal{I}_{n,0} (x). \] (B.1)

Denoting \( R^{(1,2)}_{k'k} \equiv (2m_f)^2 R^{(1,2)}_{k'k} \) we obtain the following expressions for the amplitudes with the vertices of the scalar, pseudoscalar, vector or axial vector types

\[ M_{k'k}^{-+} = -\exp [-i\theta] \exp \left( \frac{q_{\perp}^2 + q_{\parallel}^2}{4\beta} \right) \sum_{n=0}^{\infty} \frac{1}{n!} \left( \exp \left[ \frac{i(q_{\perp} q_{\perp}')}{2\beta} \right] \left( \frac{(q_{\perp} q_{\perp}')}{2\beta} \right)^n \frac{R^{(1)}_{k'k}}{P_{\perp}^2 - m_f^2 - 2\beta n} \right) \]

\[ + \exp \left[ \frac{-i(q_{\perp} q_{\perp}')}{2\beta} \right] \left( \frac{(q_{\perp} q_{\perp}')}{-2\beta} \right)^n \frac{R^{(2)}_{k'k}}{P_{\parallel}^2 - m_f^2 - 2\beta n}, \] (B.2)
where

\[ R^{(1)}_{SS} = g s g'_{j'Sj'} [(K_1 P) + m_f K_3] ; \quad (B.3) \]

\[ R^{(2)}_{SS} = R^{(1)}_{SS}(q \leftrightarrow -q') ; \quad (B.4) \]

\[ R^{(1)}_{PS} = g s g'_{j'Ps} [(K_2 P) - m_f K_4] ; \quad (B.5) \]

\[ R^{(2)}_{PS} = -g s g'_{j'Pj'} [(K_2 P') + m_f K_4] ; \quad (B.6) \]

\[ R^{(1)}_{VS} = g s g'_{j'Vs} \left\{ (P\tilde{\Lambda} j') K_3 + (P\tilde{\varphi} j') K_4 + m_f (K_1 j') \right\} - \frac{2\beta n}{q_F^2} \left[ (q'\Lambda j') - i(q'\varphi j') \right] K_3 ; \quad (B.7) \]

\[ R^{(2)}_{VS} = g s g'_{j'Vs} \left\{ (P'\tilde{\Lambda} j') K_3 - (P'\tilde{\varphi} j') K_4 - m_f (K_1 j') \right\} + \frac{2\beta n}{q_F^2} \left[ (q'\Lambda j') + i(q'\varphi j') \right] K_3 ; \quad (B.8) \]

\[ R^{(1)}_{AS} = g s g'_{j'As} \left\{ (P\tilde{\Lambda} j') K_4 + (P\tilde{\varphi} j') K_3 - m_f (K_1 j') \right\} - \frac{2\beta n}{q_F^2} \left[ (q'\Lambda j') - i(q'\varphi j') \right] K_4 ; \quad (B.9) \]

\[ R^{(2)}_{AS} = g s g'_{j'As} \left\{ (P'\tilde{\varphi} j') K_3 - (P'\tilde{\Lambda} j') K_4 - m_f (K_2 j') \right\} - \frac{2\beta n}{q_F^2} \left[ (q'\Lambda j') + i(q'\varphi j') \right] K_4 ; \quad (B.10) \]

\[ R^{(1)}_{PP} = -g P g'_{j'Pj'} [(K_1 P) - m_f K_3] ; \quad (B.11) \]

\[ R^{(2)}_{PP} = R^{(1)}_{PP}(q \leftrightarrow -q') ; \quad (B.12) \]

\[ R^{(1)}_{VP} = -g P g'_{j'Pj'} \left\{ (P\tilde{\Lambda} j') K_4 + (P\tilde{\varphi} j') K_3 + m_f (K_2 j') \right\} - \frac{2\beta n}{q_F^2} \left[ (q'\Lambda j') - i(q'\varphi j') \right] K_4 ; \quad (B.13) \]

\[ R^{(2)}_{VP} = g P g'_{j'Pj'} \left\{ (P'\tilde{\varphi} j') K_3 - (P'\tilde{\Lambda} j') K_4 + m_f (K_2 j') \right\} - \frac{2\beta n}{q_F^2} \left[ (q'\Lambda j') + i(q'\varphi j') \right] K_4 ; \quad (B.14) \]
Generalized two-point tree-level amplitude...

\[ R^{(1)}_{AP} = -g_{AP} g'_{jP} \left\{ (P \tilde{A} j') K_3 + (P \tilde{\varphi} j') K_4 - m_f (K_{1j'}) \right\} - \frac{2 \beta n}{q_z^2} [(q' j') - i(q' \varphi j')] K_3 \];  
\[ (B.15) \]

\[ R^{(2)}_{AP} = g_{AP} g'_{jP} \left\{ (P' \tilde{A} j') K_3 - (P' \tilde{\varphi} j') K_4 - m_f (K_{1j'}) \right\} + \frac{2 \beta n}{q_z^2} [(q' j') + i(q' \varphi j')] K_3 \];  
\[ (B.16) \]

\[ R^{(1)}_{VV} = g_V g'_V \left\{ (P \tilde{A} j') (K_{1j}) + (P \tilde{\varphi} j') (K_{1j}) - (j \tilde{A} j') (K_1 P) \right\}  
+ m_f [(j \tilde{A} j') K_3 + (j \tilde{\varphi} j') K_4]  
+ \frac{2 \beta n}{q_z^2} [(j \Lambda j') - i(j \varphi j')][(K_1 P) - m_f K_3][(q \Lambda q') + i(q \varphi q')]  
- \frac{2 \beta n}{q_z^2} (K_{1j}) [(q' \Lambda j') - i(q' \varphi j')] - \frac{2 \beta n}{q_z^2} (K_{1j'}) [(q \Lambda j) + i(q \varphi j)] \};  
\[ (B.17) \]

\[ R^{(2)}_{VV} = R^{(1)}_{VV} (q \leftrightarrow -q') \];

\[ (B.19) \]

\[ R^{(2)}_{AV} = g_V g'_{A} \left\{ (P' \tilde{A} j') (K_{2j}) + (P' \tilde{\varphi} j') (K_{2j'}) - (j \tilde{A} j') (K_2 P') \right\}  
+ m_f [(j \tilde{A} j') K_4 - (j \tilde{\varphi} j') K_3]  
+ \frac{2 \beta n}{q_z^2} [(j \Lambda j') + i(j \varphi j')][(K_2 P') - m_f K_4][(q \Lambda q') - i(q \varphi q')]  
+ \frac{2 \beta n}{q_z^2} (K_{2j}) [(q' \Lambda j') + i(q' \varphi j')] + \frac{2 \beta n}{q_z^2} (K_{2j'}) [(q \Lambda j) - i(q \varphi j)] \};  
\[ (B.20) \]
\[ R_{AA}^{(1)} = g_A g'_A \left\{ (P\tilde{\Lambda}j')(K_{1j}) + (P\tilde{\Lambda}j)(K_{1j'}) - (j\tilde{\Lambda}j')(K_1P) \right\} \]
\[ -m_f[(j\tilde{\Lambda}j')K_3 + (j\tilde{\phi}j')K_4] \]
\[ + \frac{2\beta n}{q^2} [(j\Lambda j' - i(j\phi j')][(K_1P) + m_f K_3][(q\Lambda q') + i(q\phi q')] \]
\[ - \frac{2\beta n}{q^2} (K_{1j}) (q'\Lambda j') - i(q'\phi j')\right\} \]
\[ R_{AA}^{(2)} = R_{AA}^{(1)}(q \leftrightarrow -q') \quad (B.22) \]

We note that the obtained results allow us to extract the limiting case \( n = 0 \). In particular, the amplitude \( M_{-VV} \) containing the vector vertices only, coincides after corresponding transformations with the amplitude of the Compton process in a strong magnetic field, calculated earlier in Ref. 16 (see also Ref. 37 where the amplitude of the type \( M_{-AV} \) was considered for the case \( \ell' = \ell = n = 0 \)). In addition, it is easy to check that the resulting amplitudes containing the vector vertices, are manifestly gauge invariant.

**Appendix C. The set of expressions for the amplitudes for forward scattering**

For generalization of the results obtained in Ref. 8 to the case of magnetized plasma we consider the process of a coherent scattering of the generalized current \( j \) off the real fermions without change of their states (the “forward” scattering). We remind that in this case we mean under the generalized current \( j \) in the initial state only the field operator of a single particle, while the generalized current \( j' \) in the final state could be both the field operator of a single particle, and e.g. the neutrino current. In this case: \( \ell = \ell' \), \( s = s' \), \( q^\mu = q'^\mu \), \( p^\mu = p'^\mu \), \( K_{1\alpha} = 2(p\tilde{\Lambda})_\alpha \), \( K_{2\alpha} = 2(\tilde{\phi}p)_\alpha \), \( K_3 = 2M_\ell \), \( K_4 = 0 \).

Since this is a coherent process, the total scattering amplitude is obtained by summing over all states of the medium fermions. We obtain the following results for the summed generalized amplitudes:

\[ M_{k'k} = -\frac{\beta}{2\pi^2} \sum_{\ell,n=0}^{\infty} \int \frac{dp}{E_\ell} f_f(E_\ell) \]
\[ \times \left\{ \frac{D_{kk}^{(1)}}{(p+q)^2 - m_f^2 - 2\beta n} + \frac{D_{kk'}^{(2)}}{(p-q)^2 - m_f^2 - 2\beta n} \right\}, \]

where \( f_f(E_\ell) = [1 + \exp \left( E_\ell - \mu_f \right)/T]^{-1} \) is the fermion distribution function, \( T \) and
\( \mu_f \) are the temperature and the chemical potential of plasma correspondingly,

\[
\mathcal{D}_{SS}^{(1)} = g_s g'_s j_s j'_s \left\{ \left[ (q \bar{\Lambda} p) + 2 \beta \ell + 2m_f^2 \right] \right. \\
\times \left( T_{n,\ell}^2 + T_{n-1,\ell-1}^2 \right) - 4 \beta \sqrt{n \ell} I_{n,\ell} I_{n-1,\ell-1} \right\}; \\
\mathcal{D}_{SS}^{(2)} = \mathcal{D}_{SS}^{(1)}(q \rightarrow -q); \\
\mathcal{D}_{SP}^{(1)} = \mathcal{D}_{PS}^{(2)} = g_s g'_p j_p j'_p (q \bar{\varphi} p) \left[ T_{n,\ell}^2 - T_{n-1,\ell-1}^2 \right]; \\
