Objectives: To determine the prevalence of incidental maxillary sinus findings in a large sample of orthodontic patients by cone-beam computed tomography (CBCT) with a wide field of view and assess the relationships of such abnormalities with age and gender. Methods: Five hundred thirteen CBCT scans obtained for orthodontic diagnosis and treatment planning in a Northern Italian population (N = 513; 292 female and 221 male subjects; 1,026 maxillary sinuses) were studied. The frequencies of pseudocysts and mucosal thickening of the maxillary sinus were recorded. Logistic regression analysis was used to determine the influence of age and gender on these abnormalities. Results: Pseudocysts were detected in 52 patients (10.1%) and 59 sinuses (5.75%). Mucosal thickening was observed in 206 patients (40.1%) and 258 sinuses (25.1%). Gender and age were significantly associated with pseudocysts (p = 0.027) and mucosal thickening (p < 0.001), respectively. Conclusions: Half of the orthodontic patients had incidental maxillary sinus findings. Men were more likely to show pseudocysts, and older patients (aged 41 - 60 years) were more likely to show mucosal thickening.

Key words: Computed tomography, Three dimensional diagnosis and treatment planning

INTRODUCTION

The advent of cone-beam computed tomography (CBCT) represents a great improvement in the field of craniofacial imaging. Unlike traditional two-dimensional (2D) radiography, CBCT avoids structural superimposition and image enlargement and distortion, thus allowing precise three-dimensional (3D) visualization of dental and maxillofacial structures at a lower radiation dose than multislice computed tomography (CT). Such imaging frequently presents the dentist or orthodontist with incidental findings and may raise concerns about the need for further diagnostic tests or referral to other specialists.

Incidental findings are common in the maxillary sinus. Although earlier studies using CBCT for dental diagnostic purposes have already addressed this issue, only one study using CBCT focused on incidental maxillary sinus findings in orthodontic patients. However, the study was limited by the small sample size and imaging with a narrow field of view (FOV), which does not allow accurate assessment of sinus pathology.

The aims of this retrospective study were to determine the prevalence of incidental maxillary sinus findings in a large sample of orthodontic patients by CBCT with a wide FOV and assess the relationships of such abnormalities with age and gender.

MATERIAL AND METHODS

Sample

This study included 680 CBCT images obtained for orthodontic diagnosis and treatment planning at the Department of Orthodontics, University of Ferrara, Italy, between January 2005 and December 2010. The protocol was approved by the local Institutional Review Board.

Images of patients with fixed orthodontic appliances, implants, or metallic prosthesis in the maxillary posterior region that could generate scattering phenomena, craniofacial syndromes, or cleft palate were excluded. Finally, 513 CBCT scans of Northern Italian patients (N = 513; 292 female and 221 male subjects; 1,026 maxillary sinuses) were selected. For statistical analysis, the subjects were divided into the following age groups: 12 - 18, 19 - 25, 26 - 40, and 41 - 60 years. The age and gender distributions are shown in Table 1.

CBCT scanning

CBCT was performed by using a NewTom 3G volume scanner (QR srl, Verona, Italy) under the following conditions: 12-inch FOV, 110 kV (anterior posterior-latero lateral), 2.00 mA (anterior posterior), 1.00 mA (latero lateral), 5.4-s exposure, and 0.50-mm slice thickness.

The resulting images were elaborated by using NNT NewTom 3G software to obtain the axial sections in which the maxillary sinus could best be distinguished. Then, a line was traced through the greatest mesiodistal dimension of the most suitable sections and various 0.2-mm-spaced coronal sections of the maxilla perpendicular to this line were obtained.

The CBCT scans were reviewed independently by 2 orthodontists trained by a radiologist with experience of over 1,000 NewTom scans at the time of the study. The diagnostic criteria were developed on the basis of the published literature, and in the case of a disagreement, a consensus was reached after a discussion between the observers. Each observer separately performed all the measurements by using the same computer (50-inch

liquid crystal display monitors, ASUS VW246H; ASUS, Taípe, Taíwan) and screen resolution (brightness, 300 cd/m²; resolution, 1,920 × 1,080).

**Assessment of pseudocysts**
Pseudocysts were diagnosed as homogeneous, dome-shaped, noncorticated soft tissue opacities with a smooth and well-defined outline in the maxillary sinus (Figure 1). For statistical analysis, the pseudocysts were categorized according to their greatest diameter (small, < 1 cm; medium, 1 - 2 cm; large, > 2 cm) and location (right, left, or bilateral).

**Assessment of mucosal thickening**
Mucosal thickening was considered present when the thickness of the sinus mucosa was ≥ 1 mm as measured from the floor of the sinus to the highest border of the mucosa (Figure 2). For statistical analysis, this pathology was classified according to the degree of sinus opacification (limited, < 1/3; moderate, 1/3 - 2/3; severe, > 2/3) and location (right, left, or bilateral).

**Calibration and reliability**
The 2 observers were calibrated for evaluation by together reviewing and discussing the findings of 20 sample CBCT images (10 per pathology) that had been

CI, Confidence interval.
diagnosed as either pseudocysts or mucosal thickening by an experienced radiologist. Each examiner measured and evaluated all the CBCT images twice, on 2 days a week apart. The intra-observer and interobserver agreements were excellent for the linear measurements (intraclass correlation coefficients [ICCs], > 0.92) and very good for the degree of sinus opacification (kappa, > 0.80).

Statistical analysis
The descriptive statistics are presented as frequencies, and the corresponding 95% confidence intervals (CI) were also calculated. Logistic regression analysis was performed to determine the effects of gender and age on the pathologies. The results are presented in terms of odds ratio increments with respect to a baseline profile, which was set as that pertaining to a 14-year-old female patient. Statistical analyses were performed by using SPSS for Windows software (version 16.0; SPSS Inc., Chicago, IL, USA). The level of significance was set at 0.05.

RESULTS

Tables 2 and 3 show the results of the incidental maxillary sinus findings. In total, 258 patients (50.3%) and 317 sinuses (30.9%) had pathologies, with 38.8% and 11.5% of the subjects showing bilateral and unilateral incidental findings, respectively. Pseudocysts were detected in 52 patients (10.1%) and 59 sinuses (5.75%), and 38 of the 59 pseudocysts were small. Further, mucosal thickening was observed in 206 patients (40.1%) and 258 sinuses (25.1%), and 176 of these sinuses presented limited opacification. Either one or both sinuses of 3 (0.6%) and 26 (5.1%) patients showed large pseudocysts and severe opacification, respectively.

Gender was a significant predictor of pseudocysts ($p = 0.027$), with male subjects showing a 196.3% higher relative risk of this pathology. Age was a significant predictor of mucosal thickening ($p < 0.001$), with subjects aged 41 - 60 years showing a 401% higher odds ratio than those aged 12 - 18 years.

DISCUSSION

In this study, 513 CBCT images obtained for orthodontic diagnostic purposes in a Northern Italian population were retrospectively evaluated. Overall, half of the patients had incidental findings in the maxillary sinus. A lower prevalence (19%) in 5,021 Finnish dental patients has been reported by using panoramic radiography, which is not as reliable as 3D imaging techniques for diagnosing maxillary sinus pathologies. The reported incidence of this pathology on panoramic radiographs varies between 6.5% and 16.4% in a dental population and 12% in a general dental population. In the present study, they were diagnosed in 10.1% of the subjects and male patients showed a greater risk, in accordance with previous findings. The reported incidences on CBCT scans vary between 6.5% and 16.4% in a dental population and from 3.5% to 19.4% in an orthodontic sample. However, comparisons with the published data should be made cautiously because of the lack of adequate diagnostic criteria.

Because the normal thickness of the maxillary sinus mucosa is 0.8 - 1.0 mm, we considered a thickness of ≥ 1 mm as evidence of mucosal thickening. The incidence of this pathology on panoramic radiographs has been reported to be between 3% in an orthodontic population and 12% in a general dental population. In the present study, we noted mucosal thickening in 40.1% of the subjects, in accordance with the incidences (38.1% and 42.0%, respectively) reported by Ritter et al. and Phothikhun et al. among dental patients. This result is higher than the prevalences (23.7% and 7.5%, respectively) reported by Pazera et al. and Cha et al. in orthodontic patients. Again, the different age and patient groups as well as the different definitions and diagnostic criteria for the pathologic changes may account for these discrepancies. Patients aged 41 - 60 years showed the highest risk of mucosal thickening in the maxillary sinus, supporting previous reports of a higher prevalence of true cystic structures usually detected by histologic examination, many authors use the term “retention cyst” as “pseudocyst.” Their incidence on panoramic radiographs has been reported to be between 5.8% in an orthodontic population and 7.0 - 9.7% in a general dental population. In the present study, they were diagnosed in 10.1% of the subjects and male patients showed a greater risk, in accordance with previous findings. The reported incidences on CBCT scans vary between 6.5% and 16.4% in a dental population and from 3.5% to 19.4% in an orthodontic sample. However, comparisons with the published data should be made cautiously because of the lack of adequate diagnostic criteria.

Although pseudocysts, sometimes called mucosal cysts or polypoid mucosal thickening, should be differentiated from mucous retention cysts, which are epithelial-lined true cystic structures usually detected by histologic examination, many authors use the term “retention cyst” as “pseudocyst.” Their incidence on panoramic radiographs has been reported to be between 5.8% in an orthodontic population and 7.0 - 9.7% in a general dental population. In the present study, they were diagnosed in 10.1% of the subjects and male patients showed a greater risk, in accordance with previous findings. The reported incidences on CBCT scans vary between 6.5% and 16.4% in a dental population and from 3.5% to 19.4% in an orthodontic sample. However, comparisons with the published data should be made cautiously because of the lack of adequate diagnostic criteria.

However, comparisons with the published data should be made cautiously because of the lack of adequate diagnostic criteria.
mucosal thickening in older individuals.\textsuperscript{4,8}

So far, no studies have directly and rigorously addressed the prevalence of pseudocysts and mucosal thickening by using CBCT for orthodontic purposes in an Italian population. These sinus abnormalities are benign and self-limiting conditions, generally seen in asymptomatic patients.\textsuperscript{8} No treatment is required unless they are associated with symptoms or considerable radiographic expansion.\textsuperscript{8} The high prevalence of incidental maxillary sinus findings in the present study is relevant to orthodontics because of the increasing use of miniscrews as temporary anchorage devices.\textsuperscript{14,15} As postoperative maxillary sinusitis is one of the most concerning sequelae after sinus perforation,\textsuperscript{16,17} CBCT evaluation for signs of inflammation in the maxillary sinus before miniscrew placement is very important from both the clinical and the medicolegal points of view. Further research is needed to determine whether these findings can be generalized to a nationally representative sample.

\textbf{CONCLUSION}

Half of the orthodontic patients showed incidental findings in the maxillary sinus, with 64.4\% of the pseudocysts being smaller than 1 cm and 68.2\% of the sinuses presenting less than one-third opacification. CBCT scans obtained for orthodontic purposes should be carefully examined in all 3 views (axial, coronal, and sagittal) to exclude any pathologic changes in the maxillary sinus and refer the patient to a specialist if necessary. Detection of signs of inflammation in the maxillary sinus is also relevant when the use of orthodontic miniscrews is planned.
