Abstract

We derive the Standard model gauge group together with chiral fermion generations from the heterotic string by turning on a Wilson line on a non-simply connected Calabi-Yau threefold with an $SU(5)$ gauge group. For this we construct stable $\mathbb{Z}_2$-invariant $SU(4) \times U(1)$ bundles on an elliptically fibered cover Calabi-Yau threefold of special fibration type (the $B$-fibration). The construction makes use of a modified spectral cover approach giving just invariant bundles.
1 Introduction

Attempts to get a (supersymmetric) phenomenological spectrum with gauge group $G_{SM}$ and chiral matter content of the Standard model from the $E_8 \times E_8$ heterotic string on a Calabi-Yau space $X$ started with embedding the spin connection in the gauge connection giving an unbroken $E_6$ (times a hidden $E_8$ coupling only gravitationally). More generally \cite{1}, one can instead of the tangent bundle embed an $G = SU(n)$ bundle for $n = 4$ or 5, leading to unbroken $H = SO(10)$ or $SU(5)$ of even greater phenomenological interest.

If there is a freely acting group $G$ on the usually simply-connected $X$, one can work on $X' = X/G$ with $\pi_1(X') = G$ allowing a further breaking of $H$ by turning on Wilson lines; the enhanced structure group $G \times G$ leads to a reduced commutator.

On $X'$ one turns on a $Z_2$ Wilson line of generator $1_3 \oplus -1_2$ breaking $H = SU(5)$ to $G_{SM}$

$$SU(5) \longrightarrow G_{SM} = SU(3)_c \times SU(2)_{ew} \times U(1)_Y$$

(up to a $Z_6$). The Wilson line $W$ can be considered as a flat bundle on $X'$ induced from the $Z_2$-cover $\rho: X \rightarrow X'$ via the given embedding of $Z_2$ in $H = SU(5)$. This gives, from \cite{1}

$\bar{5} = \bar{d} \oplus L$ and $10 = Q \oplus \bar{u} \oplus \bar{e}$, the fermionic matter content of the Standard model

$$SM \ fermions \ = \ Q \oplus L \oplus \bar{u} \oplus \bar{d} \oplus \bar{e}$$

$$= \ (3, 2)_{1/3} \oplus (1, 2)_{-1} \oplus (\bar{3}, 1)_{-4/3} \oplus (\bar{3}, 1)_{2/3} \oplus (1, 1)_2 \ \ (1.1)$$

From the decompositions of $ad_{E_8}$ under $G \times H = SU(4) \times SO(10)$ resp. $SU(5) \times SU(5)$

$$248 \ = \ (4, 16) \oplus (\bar{4}, \overline{16}) \oplus (6, 10) \oplus (15, 1) \oplus (1, 45) \ \ (1.2)$$

$$= \ (5, 10) \oplus (\bar{5}, \overline{10}) \oplus (10, \bar{5}) \oplus (\overline{10}, 5) \oplus (24, 1) \oplus (1, 24) \ \ (1.3)$$

one finds that for unbroken $SO(10)$ a consideration of the fundamental $V = 4$ is enough as all fermions, including a right-handed neutrino singlet, sit in the $16 \rightarrow \bar{5} \oplus 10 \oplus 1$. For unbroken $SU(5)$ also $\Lambda^2 V = 10$ has to be considered; but as the $10$ and the $\bar{5}$ come in the same number of families (as also demanded by anomaly considerations) it is enough to adjust $\chi(X, V)$ (the $V$-related matter) to get all the Standard model fermions.

To describe explicitly the bundle we choose $X$ elliptically fibered $\pi: X \rightarrow B$ in a specific way. For the Hirzebruch surfaces $B = F_m, m = 0, 1, 2$, $X$ turns out to be smooth. As $\pi_1(X) \neq 0$ one is actually working with a $G = SU(5)$ bundle leading to an $H = SU(5)$ gauge group on a space admitting a free involution $\tau_X$ (leaving the holomorphic three-form $\Omega$ invariant) to get a smooth Calabi-Yau $X' = X/Z_2$ over a base $B'$.

\footnote{the properly normalized hypercharge $Y$ arises by a normalization factor $1/3$}
To compute the generation number one has to work on $X$ as $X'$ does not have a section but only a bi-section (left over from the two sections of $X$) and so one can not use the spectral cover method there directly. On $X'$ the generation number is reduced by $|\mathcal{G}|$.

If the bundle $V'$ over $X'$ is a 3-generation bundle then the bundle $V = \rho^*V'$ on $X$ has 6 generations and is 'moddable' by construction. Conversely, having constructed a bundle above on $X$ with 6 generations, one assures that it can be modded out by $\tau_X$ (to get the searched for bundle on $X'$) by demanding that $V$ should be $\tau_X$-invariant. So one has to specify a $\tau_X$-invariant $SU(5)$ bundle on $X$ that, besides fulfilling some further requirements of the spectral cover construction (cf. below), leads to 6 generations. For important work related to this question cf. \cite{4}, \cite{5}, \cite{6}, \cite{7}, \cite{8} and literature cited there.

As it will be our goal to 'mod' not just the Calabi-Yau spaces but also the geometric data describing the bundle (and this transformation of bundle data into geometric data uses in an essential way the elliptic fibration structure) we will search only for actions which preserve the fibration structure, i.e., $\tau_B \cdot \pi = \pi \cdot \tau_X$ with $\tau_B$ an action on the base $\tau_X: \mathcal{Z} \to X$.

Therefore our elliptically fibered Calabi-Yau spaces will actually have 2 sections $\sigma_1$ and $\sigma_2 = \tau_X \sigma_1$ ($B$-model spaces). Turning this around, if one wants to construct $\tau_X$ by choosing a specific $X$, we will look for a Calabi-Yau $X$ with a type of elliptic fibration which has besides the usually assumed single section ($A$-model) a second one ($B$-model); this will then lead to a free involution $\tau_X$ on $Z$.

When investigating the invariance of $V$ we are led to consider a version of the spectral cover method especially adapted to the situation with two sections. Concretely we will work with a modified spectral surface and Poincaré bundle (with $\Sigma = \sigma_1 + \sigma_2$)

$$
\begin{align*}
C &= \frac{n}{2}\Sigma + \eta \\
P &= \mathcal{O}(2\Delta - \Sigma_I - \Sigma_{II} - c_1)
\end{align*}
$$

Obviously this assumes that $V$ has even rank $n$. Therefore the original strategy to obtain an $SU(5)$ gauge group (in the observable sector) from an $SU(5)$ bundle has to be modified. Concretely one choses an $SU(4)$ bundle (of commutator $SO(10)$ in $E_8$) and twists this with a further invariant line bundle $\mathcal{L}$ (of $c_1(\mathcal{L}) = D = x\Sigma + \alpha$)

$$
\mathcal{V} = V \otimes \mathcal{L}(D)
$$

\footnote{We will use the same notation for a section, its image and its cohomology class.}
The structure group is \( U(4) = SU(4) \cdot U(1)_X \) but as the difference to \( SU(4) \times U(1)_X \) is only a discrete group \( \mathbb{Z}_4 \), and group-theoretical statements are here meant on the level of Lie-algebras, we will refer to \( SU(4) \times U(1)_X \) as structure group giving \( SU(5) \times U(1)_X \) as gauge group. The anomalous \( U(1)_X \) becomes massive by the Green-Schwarz mechanism.

This bundle \( \mathcal{V} \) is then embedded in \( E_8 \) as a sum of stable bundles \( \tilde{\mathcal{V}} = \mathcal{V} \oplus \det^{-1}(\mathcal{V}) = V \otimes \mathcal{L} \oplus \mathcal{L}^{-4} \) with \( c_1(\tilde{\mathcal{V}}) = 0 \). From the condition of effectivity of the five-brane \( W \) in

\[
c_2(V) - 10D^2 + W = c_2(X)
\]

one realises that one is forced to allow for an additional twist by an invariant line bundle with \( x \neq 0 \). This however leads to a problem in the Donaldson-Uhlenbeck-Yau (DUY) condition \( c_1(V)J^2 = 0 \) where \( J = \epsilon J_0 + H_B \) is a Kahler potential for which stability of \( V \) can be guaranteed (here \( H_B \) is a Kahler class on the base). As the concrete bound \( \epsilon \leq \epsilon_* \) from which on \( J \) is appropriate is not known explicitly one has to solve the DUY equation in every order in \( \epsilon \) individually which leads for the constant term to \( 2xH_B^2 = 0 \).

Therefore one must go beyond tree-level here and invoke the one-loop correction to the DUY equation \[20\] which in turn leads to further conditions assuring positivity of the dilaton \( \phi \) and of the gauge kinetic function. These two inequalities taken together with the two inequalities assuring effectivity of \( W \) and the further inequality assuring irreducibility (resp. ampleness) of \( C \) turn out to be quite restrictive.

So we will construct rank-four vector bundles \( V \) on \( X \) which fulfill the following conditions

- \( \tilde{\mathcal{V}} \) is \( \tau_X \)-invariant and satisfies one-loop modified DUY condition
- \( c_1(\tilde{\mathcal{V}}) \equiv 0 \mod 2 \), \( c_2(X) - \left( c_2(V) - 10c_1(\mathcal{L})^2 \right) \) is effective, \( \chi(X, \tilde{\mathcal{V}}) = N_{\text{gen}} \)

Having obtained the chiral fermions of the Standard Model one would like to count also the number of Higgs multiplets and moduli. This will be considered elsewhere.

In section 2 the \( B \)-model spaces along with their cohomological data are introduced. In section 3 the modified spectral cover construction of bundles is introduced and the Chern classes of \( V \) and its twist are computed. In section 4 we are writing down for \( F_0 \) and \( F_2 \) a free involution and the \( \tau_X \)-action on \( V \) is described in detail. In section 5 we give some group-theoretical details and describe the embedding in \( E_8 \); then we make the condition for the effectivity of the ensuing fivebrane explicit. In section 6 the stability condition is made explicit and the relation with the one-loop modified DUY equation

\[\text{apart from a case, not treated in this paper, which has special features}\]
is described. Finally, in section 7 we list all numerical conditions which result from the analysis of these models.

B. A. is supported by DFG-SFB 647/A1.

2 Calabi-Yau threefold with two sections

In this paper we will consider a Calabi-Yau threefold $X$ which is elliptically fibered over a Hirzebruch surface $F_m$ and whose generic fiber is described by the so-called $B$-fiber $\mathbb{P}_{1,2,1}(4)$ instead of the usual $A$-fiber $\mathbb{P}_{2,3,1}(6)$ (the subscripts indicate the weights of $x, y, z$). $X$ is described by a generalized Weierstrass equation which embeds $X$ in a weighted projective space bundle over $F_m$

$$y^2 + x^4 + a_2x^2z^2 + b_3xz^3 + c_4z^4 = 0$$ (2.1)

where $x, y, z$ and $a, b, c$ are sections of $K_B^i$ with $i = 1, 2, 0$ and $i = 2, 3, 4$, respectively.

$X$ admits two cohomologically inequivalent section $\sigma_1, \sigma_2$. For this consider eqn. (2.1) at the locus $z = 0$, i.e., $y^2 = x^4$ (after $y \to iy$). One finds 8 solutions which constitute the two equivalence classes $(x, y, z) = (1, \pm 1, 0)$ in $\mathbb{P}_{1,2,1}$. We choose $y = +1$, corresponding to the section $\sigma_1$, as zero in the group law, while the other one can be brought, for special points in the moduli space, to a half-division point (in the group law) leading to the shift-involution, cf. section 4.1. Let us keep on record the relation of divisors

$$(z) = \Sigma := \sigma_1 + \sigma_2 \quad \quad \sigma_1 \cdot \sigma_2 = 0 \quad (2.2)$$

One finds for the Chern-classes of $X$ (cf. [13]; we use the notation $c_i = \pi^*c_i(B)$)

$$c_2(X) = 6 \Sigma c_1 + c_2 + 5c_1^2, \quad c_3(X) = -36c_1^2 \quad (2.3)$$

From the weights $a_2, b_3$ and $c_4$ of the defining equation one gets $5^2+7^2+9^2-3-3-1 = 148$ complexe structure deformations over $F_0$. This is consistent with the Euler number and the $h^{1,1}(X) = 4$ Kähler classes

$$h^{1,1}(X) = 4, \quad h^{2,1}(X) = 148, \quad \text{and} \quad e(X) = -288 \quad (2.4)$$

For later use let us also note the adjunction relations (with $\sigma_i := \sigma_i(B), i = 1, 2$)

$$\sigma_i^2 = -c_1\sigma_i, \quad \Sigma^2 = -c_1\Sigma \quad (2.5)$$

In this paper the base $B$ of $X$ is given by a Hirzebruch surface $F_m$ (with $m = 0, 2$) with $H^2(B, \mathbb{Z})$ generated by the effective base and fiber classes $b$ and $f$ (with the intersection relations $b^2 = -m, b \cdot f = 1$ and $f^2 = 0$). $\eta = xb + yf$ effective, denoted as $\eta \geq 0$, means then $x \geq 0$ and $y \geq 0$. The Kähler cone is described in the appendix.
For the description of vector bundles $V$ on $B$-fibered Calabi-Yau threefolds $X$ we will apply the spectral cover construction (equivalently a relative Fourier-Mukai transform). The spectral data are an effective divisor $C$ of $X$ ("the spectral surface") and a line bundle $L$ on $C$. The correspondence between $(C, L)$ and $V$ was described for bundles on $A$-fibered Calabi-Yau in [2], [3], [11], [12], [14] and for the $B$-fibered case in [13], [15].

For our applications let us briefly recall some facts about the spectral cover construction for the $A$-models. One first forms the fiber product $X \times_B \hat{X}$ and denote the projections on $X$ and $\hat{X}$ by $p$ and $\hat{p}$, respectively. Points $q$ on the fiber $\hat{E}_b$ of $\hat{X}$ will parametrize degree zero line bundles $L_q$ on $E_b$ for each $b \in B$; as it is usual we will identify $X \sim \hat{X}$.

There exists the so-called universal Poincaré line bundle $P$ on $X \times_B \hat{X} = X_I \times_B X_{II}$ whose restrictions to the $E_b \times q_b$ are just the $L_q$. $P$ is defined only up to a tensor product by the pullback of a line bundle on $X_{II}$ and one can normalize it by letting $P|_{\sigma_1 \times_B \hat{X}} \simeq O_X$ leading to $c_1(P) = \Delta - \sigma_1.I - \sigma_1.II - c_1$. One then considers the spectral cover surface $C \subset X$ of class $C = n\sigma_1 + \eta$ which is an $n$-fold cover of $B$ and forms the fiber product $X \times_B C$. The relative Fourier-Mukai transform constructs a vector bundle $V$ from its spectral data $(C, L)$ (where $\hat{p}_C: X \times_B C \to C$)

$$V = p_* \left( (\hat{p}_C^*L) \otimes P \right)$$

We introduce now a new procedure where we make the whole bundle construction symmetric ($\tau$-invariant) from the beginning. For this we define for even $n$ (with suitable pull-backs via $p$ and $p_{II} = \hat{p}$ understood in [33]; $\Delta$ is the diagonal in $X \times_B X$)

$$C = \frac{n}{2} \Sigma + \eta$$

$$c_1(P) = 2\Delta - \Sigma_I - \Sigma_{II} - c_1 \quad \left( p_* c_1(P) = 0 \right)$$

As we will usually assume that $C$ is effective and irreducible, let us review the conditions which we have to impose on $\eta$ to assure this. $C$ is effective exactly if $\eta$ is, what we denote by $\eta \geq 0$, and $C$ is irreducible when (cf. [III])

$$\eta \cdot b \geq 0, \quad \eta - \frac{n}{2}c_1 \geq 0.$$

Actually we will even assume that $C$ is ample (cf. appendix) so that the classification of line bundles on $C$ is discrete and $L$ is determined by $c_1(L)$ up to isomorphism. For then $h^{1,0}(C) = 0$ as $h^1(C, O_C) = h^2(X, O_X(-C))$ by the long exact sequence associated to $0 \to O_X(-C) \to O_X \to O_C \to 0$; then $h^2(X, O_X(-C)) = h^1(X, O_X(C)) = 0$ by the Kodaira vanishing theorem.
Applying the Grothendieck-Riemann-Roch theorem to the covering \( \pi_C : C \to B \) gives

\[
\text{ch}(\pi_C^*L) \text{Td}(B) = \pi_C^*(\text{ch}(L) \text{Td}(C))
\]  

(3.5)

From \( c_1(V) = 0 \) one derives thereby the general expression for \( L \) (with \( \rho := \mu + \frac{\nu}{2} \lambda \))

\[
c_1(L) = \frac{C + c_1 + \gamma}{2}
\]

(3.6)

\[
\gamma = \lambda(n \sigma_1 - (\eta - \frac{n}{2} c_1)) + \mu(\sigma_1 - \sigma_2) = \lambda\left(\frac{n}{2} \Sigma - (\eta - \frac{n}{2} c_1)\right) + \rho(\sigma_1 - \sigma_2)
\]  

(3.7)

So for \( n = 4 \), and \( \rho = 0 \) as we later have to assure invariance of \( V \) (we had chosen \( c_1 \) even), \( c_1(L) \) is an integral class if \( \lambda \in \mathbb{Z} + \frac{1}{2} \) or if \( \lambda \in \mathbb{Z} \) and \( \eta \) is even.

The Grothendieck-Riemann-Roch theorem for the covering \( p : X \times_B C \to X \) gives

\[
\text{ch}(V) \text{Td}(X) = p_* \left( (\hat{\pi}_C^* \text{ch}(L)) \text{ch}(P) \text{Td}(X \times_B C) \right)
\]

(3.8)

\[
c_2(V) = 2(\eta + \frac{n}{4} c_1) \Sigma - 2\rho(\eta - \frac{n}{2} c_1)(\sigma_1 - \sigma_2) - \rho^2 c_1(\eta - \frac{n}{2} c_1)
\]

\[
+ 2\eta c_1 + \frac{1}{2} \left( \lambda^2 - \frac{1}{4} \right) n \eta(\eta - \frac{n}{2} c_1) - \frac{n(n^2 - 1)}{24} c_1^2
\]

(3.9)

\[
\frac{1}{2} c_3(V) = 4\lambda \eta(\eta - \frac{n}{2} c_1)
\]

(3.10)

**Twisting by \( \mathcal{L}(D) \)**

For group-theoretical reasons explained later and for reasons of effectivity of the ensuing five-brane class we still have to twist our \( SU(n) \) vector bundle by an invariant line bundle \( \mathcal{L}(D) \) where \( D = x \Sigma + \alpha \) to get \( \mathcal{V} = V \otimes \mathcal{L} \) and actually then to consider \( \tilde{\mathcal{V}} = V \otimes \mathcal{L} \oplus \mathcal{L}^{-4} \).

Now let us compute the generation number. For the double covering \( \rho : X \to X' \) with vector bundles \( \tilde{\mathcal{V}} \) and \( \tilde{\mathcal{V}}' \) one has \( \chi(X, \tilde{\mathcal{V}}) = 2\chi(X', \tilde{\mathcal{V}}') \) (here \( \tilde{\mathcal{V}}' \) with \( \tilde{\mathcal{V}} = \rho^* \tilde{\mathcal{V}}' \) exists precisely because \( \tilde{\mathcal{V}} \) is invariant). \( N_{\text{gen}} \) can be computed from the index \( \chi(X, \tilde{\mathcal{V}}) \). The net-number of chiral matter multiplets (the 'number of generations') is given by (note that \( c_1(\tilde{\mathcal{V}}) = 0 \) and \( c_2 = 4, c_1^2 = 8, n = 4 \))

\[
N_{\text{gen}} = \chi(X, V \otimes \mathcal{L} \oplus \mathcal{L}^{-4}) = \int_X \text{ch}_3(V \otimes \mathcal{L}) + \text{ch}_3(\mathcal{L}^{-4})
\]

\[
= \frac{1}{2} c_3(V) - c_2(V) D - 10 D^3
\]

\[
= 4 \left[ \lambda - x(\lambda^2 - \frac{1}{4}) \right] \eta(\eta - 2c_1) + 40x(1 - 4x^2) - 4\alpha(\eta + c_1) - 60x\alpha(\alpha - xc_1)
\]

\[\text{The space of line bundles } \text{Pic}(C) \text{ on } C \text{ is generically not simply characterized by pullbacks of bundles from } X; \text{ new divisor classes on } C \text{ can appear.}\]
4 Involution and invariant bundles

4.1 Existence of a free $\mathbb{Z}_2$ operation

We give a free involution $\tau_X$ on $X$ which leaves the holomorphic three-form invariant; then $X' = X/\tau_X$ is a smooth Calabi-Yau. We assume $\tau_X$ compatible with the fibration, i.e., we assume the existence of an involution $\tau_B$ on the base $B$ with $\tau_B \cdot \pi = \pi \cdot \tau_X$.

We will choose for $\tau_B$ the following operation in local (affine) coordinates

$$b = (z_1, z_2) \xrightarrow{\tau_B} -b = \tau_B(b) = (-z_1, -z_2) \quad (4.1)$$

The idea for the construction of $\tau_X$ is to combine $\tau_B$ with an operation on the fibers. A free involution on a smooth elliptic curve is given by translation by a half-division point. Such an object has to exist globally; this is the reason we have chosen the $B$-fibration where $X$ possesses a second section. If we would tune $\sigma_2(b) \in E_b$ to be a half-division point the condition $b_3 = 0$ would ensue and $X$ would become singular. Therefore this idea has to be enhanced. Furthermore, even for a $B$-fibered $X$ those fibers lying over the discriminant locus in the base will be singular where the freeness of the shift might be lost. As the fixed point locus of $\tau_B$ is a finite set of (four) points we can assume that it is disjoint from the discriminant locus (so points in the potentially dangerous singular fibers are still not fixed points of $\tau_X$; for discussion cf. [13], [15]).

One finds [13] as $\tau_X$ over $F_m$ with $m$ even (i.e., $m$ being 0 or 2) the free involution

$$(z_1, z_2; x, y, z) \xrightarrow{\tau_X} (-z_1, -z_2; -x, -y, z) \quad (4.2)$$

This exchanges the points $\sigma_1(b) = (b; 1, 1, 0)$ and $\sigma_2(-b) = (-b; 1, -1, 0)$ between the fibers $E_b$ and $E_{-b} = E_{\tau_B(b)}$; in $\mathbb{P}_{1,2,1}$ the sign in the $x$-coordinate can be scaled away here in contrast to the sign in the $y$-coordinate. As indicated above an involution like in eqn. (4.2) could not exist on the fiber alone, i.e. as a map $(x, y, z) \rightarrow (-x, -y, z)$, because this would from eqn. (2.1) force one to the locus $b_3 = 0$ where $X$ becomes singular (so only then is this defined on the fiber and so, being a free involution, a shift by a half-division point). But it can exist combined with the base involution $\tau_B$ on a subspace of the moduli space where the generic member is still smooth: from eqn. (2.1) the coefficient functions should transform under $\tau_X$ as $a_2^+, b_3^-, c_4^+$, i.e., over $F_0$, say, only monomials $z_1^p z_2^q$ within $b_{6,6}$ with $p + q$ even are forbidden; similarly in $a_{4,4}$ and $c_{8,8}$ $p + q$ odd is forbidden. So the number of deformations drops to $h^{2,1}(X) = (5^2 + 1)/2 + (7^2 - 1)/2 + (9^2 + 1)/2 - 1 - 1 - 1 = 75$. The discriminant remains generic since enough terms in $a, b, c$ survive, so $Z$ is still smooth (cf. [13]). The Hodge numbers $(4, 148)$ and $(3, 75)$ of $X$ and $X'$ show that indeed $e(X') = e(X)/2$ ($X'$ has lost one divisor as the two sections are identified).
4.2 Invariance of the bundles

We describe conditions on the spectral data \((C, L)\) for the \(\tau_X\)-invariance of \(V\). The surface \(C\) lies actually in the dual Calabi-Yau \(\hat{X}\) where \(\hat{\tau}\) operates (cf. the next subsection): \(\hat{V} = \tau^*V\) turns out to be again a spectral cover bundle with \(\hat{C} := \hat{\tau}(C)\) as spectral surface. As fiberwise semistable bundle it is fixed up to the datum \(\hat{L}\). More precisely the argument for invariance now goes as follows. The symmetric form (in \(\sigma_1\) and \(\sigma_2\) of \(P\) suggests that \(V\) should be invariant if \(L\) is chosen also symmetric, i.e. \(\rho = 0\). However one has to take into account that on the part of \(FM\) sits in \(X\) between \(C\) of data in the framework of Fourier-Mukai transformations. Because of the difference the discussion above and related invariance arguments.

\[ \tau\rho \text{ gives } \rho = 0 \text{ as necessary and sufficient condition for invariance.} \]

**Remark on Fourier-Mukai transformation**

Usually the spectral cover construction of \(V\) from \((C, L)\) is interpreted as an equivalence of data in the framework of Fourier-Mukai transformations. Because of the difference between \(C\) and \(C_{\text{eff}}\) (cf. next subsection) occurring in our construction we will not employ the idea of an inverse transform here. Let us nevertheless point to some facts related to the discussion above and related invariance arguments.

\(\hat{V} = \tau^*V\) is the Fourier-Mukai transform \(FM^0\) of a line bundle \(\hat{L} = j^*\hat{l}\) supported on \(\hat{C} = \hat{\tau}(C)\), where \(j : \hat{C} \hookrightarrow X\), i.e., \(\tau^*FM^0i_*i^*l = FM^0j_*j^*\hat{l}\) where \(L = i^*l\) was the line bundle datum on \(C\) for \(V\) (here \(i : C \hookrightarrow X\)). For this recall that for \(\hat{V}\) a semistable vector bundle of rank \(n\) and degree zero on the fibers its inverse Fourier-Mukai transform \(FM^1(\hat{V})\) is a torsion sheaf of pure dimension two on \(X\) and of rank one over its support which is a surface \(j : \hat{C} \hookrightarrow X\), finite of degree \(n\) over \(B\). For \(\hat{C}\) smooth \(FM^1(\hat{V}) = j_*\hat{L}\) is just the extension by zero of some torsion free rank one sheaf which is actually a line bundle \(\hat{L} \in Pic(\hat{C})\): for \(\pi_{\hat{C}} : \hat{C} \rightarrow B\) is locally free and \(\pi_{\hat{C}} : \hat{C} \rightarrow B\) is a finite flat surjective morphism so \(\hat{L}\) is locally free as well.

Now for a Poincaré bundle which would be strictly invariant in the sense that \((\tau \times \hat{\tau})^*P = P\) one can indeed show that \(\tau^*FM^0(E) = FM^0(\tau^*E)\) (here \(E = i_*L\)). For this note that

\[
\tau^*FM^0(E) = \tau^*\pi_*(\hat{\tau}^*E \otimes P) = \pi_*(\hat{\tau}^*E \otimes P) = FM^0(\hat{\tau}^*E) \tag{4.3}
\]

Thus one gets invariance if \(FM^0(\hat{\tau}^*E) = FM^0(E)\) for which it is sufficient that \(\hat{\tau}^*E = E\).
4.3 Operation on the dual Calabi-Yau \( \hat{X} \)

Let us see how \( \tau_X \) operates effectively in the dual Calabi-Yau \( \hat{X} \). \( E_b \) has the equation

\[
y^2 = x^4 + a_2^+(b)x^2z^2 + b_3^-(b)xz^3 + c_4^+(b)z^4
\]

Similarly \( E_{-b} \) with \( -b := \tau_B(b) \) has the equation

\[
y^2 = x^4 + a_2^+(b)x^2z^2 - b_3^-(b)xz^3 + c_4^+(b)z^4
\]

\( \tau \) maps \( E_{-b} \) to \( E_b \) and one gets for the transformed bundle

\[
V|_{E_b} = \bigoplus_{i=1}^{n} \mathcal{O}_{E_b}(q_i(b) - \sigma_1(b)) \implies (\tau^*V)|_{E_b} = \bigoplus_{i=1}^{n} \mathcal{O}_{E_b}(\tau q_i(-b) - \sigma_2(b))
\]

As \( \mathcal{O}_{E_b}(\tau q_i(-b) - \sigma_2(b)) \cong \mathcal{O}_{E_b}(t_{\sigma_2(b)}^{-1} \tau q_i(-b) - \sigma_1(b)) \) where \( t_{\sigma_2(b)} \) is the translation in the group law one finds that \( \tau^*V = V \) amounts fiberwise to the relation \( \{q_i(b)\} = \{t_{\sigma_2(b)}^{-1} \tau q_i(-b)\} \), i.e., to \( t_{\sigma_2}^{-1} \tau C = C \). So \( \hat{\tau} := t_{\sigma_2}^{-1} \circ \tau \) is the relevant operation \( \hat{\tau} \) on \( \hat{X} \)

\[
\tau_X = t_{\sigma_2} \circ \hat{\tau}
\]

We did not assume that \( \sigma_2(b) \) is a half-division point (so \( t_{\sigma_2} \) is not an involution); if one would do so by tuning \( b_3 = 0 \) the space \( X \) would become singular and only then acts \( t_{\sigma_2} \) as \( (b; x, y, z) \to (b; -x, -y, z) \).

Actions in coordinates and in the group structure

Involutions \( \tau_X \) covering \( \tau_B \) (in the sense of eqn. (1.4)) are determined by involutions \( \alpha \) (which turns out to be \( \hat{\tau} \) in our case) covering \( \tau_B \) with \( \alpha \sigma_{1/2} = (-1) \sigma_{1/2} \) (the minus refers to the inversion in the group law). (Cf. also [6].)

Now let us define a decomposition of \( \tau \) in the coordinate involutions

\[
\tau = \iota \circ \beta
\]

with \((\iota, \text{ covering } 1_B, \) is fiberwise the covering involution for the obvious map to \( \mathbb{P}^1_{x,y,z} \))

\[
\iota : (b; x, y, z) \to (b; x, -y, z) \quad , \quad \beta : (b; x, y, z) \to (-b; -x, y, z)
\]

(\( \beta \) keeps \( \sigma_i \) fixed). One has the following relation between coordinate map and the structural maps (note that both sides just act on the fiber and interchange the \( \sigma_i \))

\[
\iota = t_{\sigma_2} \circ (-1)
\]

First note here that \( \iota \) is independent of the element \( q \) chosen as group zero; similarly the translation becomes in general \( (t_{\sigma_2})_q = t_{\sigma_2} \circ t_q^{-1} \) and the inversion \( (-1)_q = t_q \circ (-1) \), so the right hand side is independent of the zero chosen.
Concerning the proof of eqn. (4.10) note that a holomorphic map on the fiber $C/\Lambda$ is $t_q \circ \rho$ with $\rho$ a group homomorphism, $t_q$ a translation (here $q$ must be $\sigma_2$). $\rho$ lifts to a linear transformation $z \to az + b$ of $C$ ($b \in \Lambda$), so $a$, keeping invariant the lattice $\Lambda$, is in $\mathbb{Z}$ ($C/\Lambda$ in general has no complex multiplication); $\rho$ is an isomorphism as $\iota$ is, so $a = \pm 1$ and $a = -1$ as $\rho \sigma_2 = (-1) \sigma_2$. 

$$\tau = \iota \circ \beta = t_{\sigma_2} \circ (-1) \circ \beta = t_{\sigma_2} \circ \hat{\tau}$$ (4.11)

**Application to the spectral points**

For the choice of our Poincare bundle in $V = p_*(p^*C L \otimes P)$ one finds

$$P|_{E \times q} = \mathcal{L}((2q - \sigma_2) - \sigma_1)$$ (4.12)

giving effective spectral points $C^{eff} = \{2q - \sigma_2 | q \in C\}$ ("2" and "−" refer to the group).

What we actually want to achieve is that $\hat{\tau} C^{eff} = C^{eff}$ as the $\hat{\tau}$-invariance condition concerns the points $q_i^{eff}$ corresponding to line bundle summands on the fiber. $\beta$, being holomorphic and sending $\sigma_1$ to itself, is a group homomorphism between respective fibers. With $2q - \sigma_2 = q - \iota q$ (operations in the group) from eqn. (4.10), one gets as condition

$$( -1) \beta (1 - \iota) q_i(b) = (1 - \iota) q_i(-b)$$ (4.13)

As $(-1)$ and $\beta$ are group homomorphisms this will be fulfilled if we can assure that

$$q_i(-b) = \iota \beta q_i(b)$$ (4.14)

That is, the reduction achieved amounts to (note that fiberwise $C^{eff} = (1 - \iota) C$)

$$\iota \beta C = C \implies ( -1) \beta C^{eff} = C^{eff}$$ (4.15)

**The equation of the spectral cover surface**

To show how this condition can be implemented we give the coordinate description of our spectral cover surface $C$. In the appendix we recall the corresponding relations in the $A$-model elliptic fibration and derive the expression for our case.

From there one gets the equation of a spectral cover surface $C$ (for $n = 4$)

$$w = \alpha_{20} x^2 + \alpha_{02} y + \alpha_{10} x z + \alpha_{00} z^2 = 0$$ (4.16)

This shows that invariance of $C$ under $\beta$ would mean that the coefficient functions $\alpha_{ij}$ transform invariantly under $\tau_B$ except $\alpha_{10}$ which should transform anti-invariantly (or the other way around); similarly invariance of $C$ under $\iota \beta$ as in eqn. (4.14) (to assure the necessary $\hat{\tau} = ( -1) \beta$-invariance of $C^{eff}$) means that $\alpha_{02}$ and $\alpha_{10}$ have to transform with the other sign then $\alpha_{20}$ and $\alpha_{00}$, a condition which can easily be imposed.
5 The $E_8$ embedding and the massive $U(1)$

We will explain now more precisely our strategy outlined in the introduction how to get an $SU(5)$ GUT group and describe the embedding of the structure group into $E_8$.

The spectral cover construction leads in general to $U(n)$ bundles $V$ (the 'non-split case') with $c_1(V) = \alpha$, cf. \(\mathfrak{n}\). For us it will enough to consider the 'split case'

$$V = V \otimes \mathcal{L}(D)$$  \hspace{1cm} (5.1)

where $V$ is an $SU(n)$ bundle and $\mathcal{L}(D)$ is a line bundle of $c_1(\mathcal{L}(D)) = D = x\Sigma + \alpha$. So $c_1(V) \equiv 0(n)$ as $D$ is integral. Conversely, if $c_1(V) \equiv 0(n)$, one can split off an integral class $D$ of $c_1(V) = nD$ and define a corresponding line bundle $\mathcal{L}(D)$ such that $V := V \otimes \mathcal{L}(-D)$ is an $SU(n)$ bundle, i.e., one can think of $V$ then as $V \otimes \mathcal{L}(D)$.

Note that the structure group $U(n)$ arises in this case from $SU(n) \cdot U(1)$ (the latter factor is understood here always as embedded by multiples of the identity matrix) whereas for a bundle $V \oplus \mathcal{L}(D)$ the structure group would be the direct product $SU(n) \times U(1)$. Let us make the embedding of $G$ in $E_8$ more explicit. One embeds a $U(4)$ bundle block-diagonally via $U(4) \ni A \rightarrow \begin{pmatrix} \Lambda & 0 \\ 0 & \Lambda^{-1} \end{pmatrix} \in SU(5)$. In our case $V = V \otimes \mathcal{L}$ with $c_1(V) = 4c_1(\mathcal{L})$, so in this sense one works actually with the bundle $\tilde{V} = V \oplus \mathcal{L}^{-4}$.

The commutator of $G = SU(4) \times U(1)_X$ in $E_8$ is given by $H = SU(5) \times U(1)_X$, the observed gauge group. The adjoint representation of $E_8$ decomposes under $SU(4) \times SU(5) \times U(1)_X$ as follows (with $ad(E_8) = \bigoplus_i U_i^{SU(4)} \otimes R_i^{SO(10)} = \bigoplus_i (U_i, R_i) = \bigoplus_i (U_i, S_i^{SU(5)})_{\nu(1)}$)

\[
\begin{align*}
SU(5) \times SU(5) & \rightarrow \quad (5, 10) \oplus (5, \overline{10}) \oplus (10, 5) \oplus (\overline{10}, 5) \oplus (24, 1) \oplus (1, 24) \\
SU(4) \times SU(5) \times U(1)_X & \rightarrow \quad (4, 1)_{-5} \oplus (4, \overline{5})_3 \oplus (4, 10)_{-1} \oplus (\overline{4}, 1)_5 \oplus (\overline{4}, 5)_{-3} \oplus (\overline{4}, \overline{10})_1 \\
& \quad \oplus (6, 5)_2 \oplus (6, \overline{5})_{-2} \\
& \quad \oplus (15, 1)_0 \oplus (1, 1)_0 \oplus (1, 10)_4 \oplus (1, \overline{10})_{-4} \oplus (1, 24)_0
\end{align*}
\]
The $SU(5)$ representations are given as an auxiliary step. The full decomposition, identical to an auxiliary $SU(4) \times SO(10)$ step, leads to the right-handed neutrino $\nu_R$.

The massless (charged) matter content is $\bigoplus (S_k)_{t_k} = 1_{-5} \oplus 5_3 \oplus 10_{-1} \oplus 5_{-2} \oplus 10_4$; one can write conditions for the absence of net generations of the exotic matter given by the last two summands; additionally (besides the gauge bosons $(1, 1)_0 \oplus (1, 24)_0$ of $H$) some neutral matter given by singlets (moduli) arises from $\text{End}(V)$, i.e., $(15, 1)_0$.

Precisely those $U(1)$’s in $H$ which occur already in $G$ (a so-called $U(1)$ of type I; other $U(1)$’s in $H$ are called to be of type II) are anomalous [16], [17], [18], [20]. The anomalous $U(1)_X$ can gain a mass by absorbing some of the would be massless axions via the Green-Schwarz mechanism, that is, the gauge field is eliminated from the low energy spectrum by combining with an axion and so becoming massive. One has to check that the anomalies related to $U(1)_X$ do not cancel accidentally (i.e., that the mixed abelian-gravitational, the mixed abelian-non-abelian and the pure cubic abelian anomaly do not all vanish). Computing the anomaly-coefficients of $U(1)_X$ we find (cf. [20])

\[
A_{U(1)-G_{\mu \nu}^3} = \sum tr(S_k)_{t_k} q \cdot \chi(X, U_k \otimes t_k) \\
= 10D \cdot \left( 12 \cdot \left( -c_2(V) + 10D^2 \right) + 5c_2(X) \right)
\] (5.3)

\[
A_{U(1)-SU(5)^2} = \sum q_k C_2(S_k) \cdot \chi(X, U_k \otimes t_k) \\
= 10D \cdot \left( 2 \left( -c_2(V) + 10D^2 \right) + c_2(X) \right)
\] (5.4)

\[
A_{U(1)^3} = \sum tr(S_k)_{t_k} q^3 \cdot \chi(X, U_k \otimes t_k) \\
= 200D \cdot \left( 6 \left( -c_2(V) + 10D^2 \right) + 40D^2 + 3c_2(X) \right)
\] (5.5)

(with $C_2$ normalised to give $C_2(\bar{f}) = 1$, $C_2(\Lambda^2 f) = 3$ for $SU(5)$). For $x \neq 0$ (the case of interest for us, cf. below) the last two conditions are not proportional as $D^3 \neq 0$. In any case the first condition is independent, so not all three coefficients will vanish.

### 5.1 Effectivity of the fivebrane

In the presence of magnetic five-branes the Bianchi identity $H$-field reads

\[
dH = \text{tr} R \wedge R - \frac{1}{30} \text{Tr} F \wedge F + \sum_{5\text{-branes}} \delta_5^{(4)}
\] (5.6)

where $R$ and $F$ are the associated curvature forms of the spin connection on $X$ and the gauge connection on $\mathcal{V}$ and the last term is the source term contributed by the five-branes. Here tr refers to the trace of the endomorphism of the tangent bundle of $X$ and Tr denotes the trace in the adjoint representation of $G$. 

13
This leads in our case of

$$\tilde{\mathcal{V}} = \mathcal{V} \oplus \mathcal{L}^{-4}$$  \hspace{1cm} (5.7)$$

to the anomaly equation

$$-ch_2(X) = -ch_2(\mathcal{V}) - ch_2(\mathcal{L}^{-4}) + W$$  \hspace{1cm} (5.8)$$

This gives with $c_1(\mathcal{V}) = -c_1(\mathcal{L}^{-4})$ and $c_1(\mathcal{L}) = D$

$$c_2(X) = c_2(\mathcal{V}) - c_1^2(\mathcal{L}^{-4}) + W$$
$$= c_2(\mathcal{V}) - 10D^2 + W  \hspace{1cm} (5.9)$$

Note that the last term in eqn. (5.6) is formally a current that integrates to one in the direction transverse to a five-brane whose class we denote by $W$. The class $W$ is the Poincaré dual of the sum of all sources and represents a class in $H_2(X, \mathbb{Z})$. Supersymmetry demands $W$ to be the class of an effective curve in $X$. For simplicity we will think of the curve of $W$ as being irreducible.

We have a factorization $\mathcal{V} = V \otimes \mathcal{L}(D)$ where $V$ is an $SU(n)$ bundle and $\mathcal{L}(D)$ is a line bundle with $c_1(\mathcal{L}(D)) = D$. With the decomposition of $W$

$$W = W_B + W_F = w_B \Sigma + a_f F$$  \hspace{1cm} (5.10)$$

(where $W_B$ is an effective curve class and $a_f \geq 0$) one finds

$$W = c_2(X) - c_2(\mathcal{V}) + 10D^2$$
$$= \left(6c_1\Sigma + c_2 + 5c_1^2\right) - 2(\eta + \frac{n}{4}c_1)\Sigma - kF + 10D^2$$
$$= \left(6c_1 - 2(\eta + \frac{n}{4}c_1) + 10x(2\alpha - xc_1)\right)\Sigma + \left(c_2 + 5c_1^2 - kF + 10\alpha^2\right)$$

giving the effectivity conditions (with $c_1^2 = 8$, $c_2 = 4$, $n = 4$)

$$w_B = 4c_1 - 2\eta + 10x(2\alpha - xc_1) \geq 0$$  \hspace{1cm} (5.12)$$
$$a_f = 48 - 2(\lambda^2 - \frac{1}{4})\eta(\eta - 2c_1) - 2\eta c_1 + 10\alpha^2 \geq 0$$  \hspace{1cm} (5.13)$$

Note that (5.12) amounts to $\eta \leq 2c_1$ for $x = 0$, i.e., to $\eta = 2c_1$ where $C$ is not ample and $h^{1,0}(C) \neq 0$. 

14
6 The DUY constraint and its 1-Loop Modification

Like the Calabi-Yau condition on the underlying space $X$, the holomorphicity and stability of the vector bundle $V$ are direct consequences of the required four-dimensional supersymmetry. The demand is that a connection $A$ on $V$ has to satisfy (at string tree level) the Donaldson-Uhlenbeck-Yau (DUY) equation ($J$ denotes a Kähler form on $X$)

$$F_A^{2,0} = F_A^{0,2} = 0, \quad F_A^{1,1} \wedge J^2 = 0 \quad (6.1)$$

The first equation implies the holomorphicity of $V$; the second equation is the Hermitian-Yang-Mills (HYM) equation $F_A^{1,1} \wedge J^{n-1} = c \cdot I_F \cdot J^n$ (for $n = 3$ with $c \in \mathbb{C}$ vanishing) with the integrability condition (condition for the existence of a unique solution in case $V$ is polystable, i.e., a sum of $\mu$-stable bundles with the same slope) [23], [24]

$$\int_X c_1(V) \wedge J^2 = 0 \quad (6.2)$$

$V$ is called $\mu$-stable with respect to some Kähler class $J$ if its slope $\mu(V) = \frac{1}{rk(V)} \int c_1(V) \wedge J^2$ is bigger than the slope of each subbundle $V'$ of smaller rank.

If $C$ is irreducible then $V$ will be stable for sufficiently small $\epsilon$ with respect to $\mathfrak{3}$

$$J = \epsilon J_0 + \pi^* H_B, \quad \epsilon > 0 \quad (6.3)$$

Here $J_0 = x_1 \sigma_1 + x_2 \sigma_2 + h$ with $x_1 + x_2 > 0$ and $H_B$ is an ample divisor in $B$. So the volume of the fiber $F$ of $X$ is kept arbitrarily small compared to volumes of effective curves in the base. For details on the stability properties and generalizations we refer to [3] [25]. Note that working on $B$-fibered Calabi-Yau threefolds does not effect the stability proof of [3]. Thus our bundles are stable with respect to the Kähler class in eqn. (6.3).

The bundle $\mathcal{V} = V \otimes \mathcal{L}(D)$ is stable with respect to $J = \epsilon J_0 + H_B$ with $\epsilon$ small positive, $H_B \in \mathcal{C}_B$ and $J_0 = x_1 \sigma_1 + x_2 \sigma_2$ (with $\mathcal{C}_B$ the Kähler cone of $B$). The DUY constraint is

$$0 = DJ^2 = -\epsilon^2 c_1(\alpha - xc_1) \left( \sum x_i^2 \right) + 2\epsilon \left( \sum x_i \right) H_B(\alpha - xc_1) + 2xH_B^2 \quad (6.4)$$

If one tries to argue that the Kähler moduli in $J$ are tuned such that $DJ^2 = 0$, one encounters the difficulty that the relevant $\epsilon$ (for which stability is known) depends itself on the chosen $J_0$ and $H_B$. So one rather has to make vanish the coefficients of the three different $\epsilon$-powers individually, so that $DJ^2 = 0$ independently of the actual, unknown value of $\epsilon$. But the constant term gives $x = 0$ for which eqn. (5.12) can not be relaxed.

For a rank $n$ bundle $\mathcal{V} = \oplus \mathcal{V}_i$ composed of $U(n_i)$ bundles of slopes $\mu_i = \frac{1}{m} \int J^2 c_1(\mathcal{V}_i) =: \mu$ (they must coincide for $\mathcal{V}$ to be polystable) one finds $\int J^2 c_1(\mathcal{V}_i) = 0$ for all $i$ as $0 = \int J^2 c_1(\mathcal{V}) = \sum r_i\mu_i = \mu n$. For us, having $c_1(\mathcal{V}_i) = \pm 4D$, this means $\int J^2 D = 0$.  

15
The 1-loop modification

We discuss now an approach which leads to a rank 5 physical bundle for a split extension and non-vanishing \( x \). This causes the slope to be non-zero and so one has to invoke the quantum corrected version of it. This will make the slope vanish at the one loop level and fix the dilaton.

From the condition of effectivity of the five-brane \( W \) in \( c_2(V) - 10D^2 + W = c_2(X) \) one realises that one is forced to allow for an additional twist by an invariant line bundle with \( x \neq 0 \). This however leads to a problem in the Donaldson-Uhlenbeck-Yau (DUY) condition \( c_1(V).J^2 = 0 \) where \( J = \epsilon J_0 + H_B \) is a Kahler class for which stability of \( V \) can be guaranteed (here \( H_B \) is a Kahler class on the base). As the concrete bound \( \epsilon \leq \epsilon_s \) for which \( J \) is appropriate is not known explicitely one has to solve the DUY equation in every order in \( \epsilon \) individually which leads for the constant term to \( 2xH_B^2 = 0 \).

Therefore one must go beyond tree-level here and invoke the one-loop correction to the DUY equation \( [20] \) which in turn leads to further conditions assuring positivity of the dilaton \( \phi \) and of the gauge kinetic function. These two inequalities taken together with the two inequalities assuring effectivity of \( W \) and the further inequality assuring irreducibility (resp. ampleness) of \( C \) turn out to be quite restrictive.

So we invoke the one-loop correction of the DUY integrability constraint \( [20], [21], [22] \) (here \( z \in \left[-\frac{1}{2}, \frac{1}{2}\right] \) refers to the position of \( W \) in the interval between the two \( E_8 \)-walls\(^5\))

\[
0 = \int_X c_1(\mathcal{L})J^2 - \phi \int_X c_1(\mathcal{L}) \left(-c_2(V) + 10c_1(\mathcal{L})^2 + \frac{1}{2}c_2(X) - \left(\frac{1}{2} - z\right)^2W\right) \quad (6.5)
\]

\[
= DJ^2 - \phi D \left[(1 - (\frac{1}{2} - z)^2)W - \frac{1}{2}c_2(X)\right] \quad (6.6)
\]

(corresponding to a deformed DUY equation) with \( \phi = t^4g^2 \) giving

\[
\phi = \frac{DJ^2}{D\left(\frac{3}{4}W - \frac{1}{2}c_2(X)\right)} = \frac{O(\epsilon) + xH_B^2}{(\alpha - xc_1)(\frac{3}{4}w_B - 3c_1) + x(\frac{3}{4}a_f - 22)} > 0 \quad (6.7)
\]

as condition. So it is enough to have (for \( x > 0 \); otherwise one has the reverse inequality)

\[
(\alpha - xc_1)(\frac{3}{4}w_B - 3c_1) + x(\frac{3}{4}a_f - 22) > 0 \quad (6.8)
\]

The positivity of the one-loop corrected gauge kinetic function requires \( [20], [21], [22] \)

\[
0 < J^3 - 3\phi \left[J\left(W - \frac{1}{2}c_2(X) - \left(\frac{1}{2} - z\right)^2W\right)\right] = O(\epsilon) - 3\phi \left[(1 - (\frac{1}{2} - z)^2)W - \frac{1}{2}c_2(X)\right]H_B
\]

As stability will hold for all small enough \( \epsilon \) it will be enough to show

\[
\left(\frac{3}{4} \left[4c_1 - 2\eta + 10x(2\alpha - xc_1)\right] - 3c_1\right)H_B < 0 \quad (6.9)
\]

\(^5\)apart from a 'separation case', which has special features

\(^6\)we choose \( z = 0 \) to illustrate; to determine \( z_W \), open membrane instanton effects have to be included
7 Model constraints and Conclusions

Let us collect all conditions on the bundle. Note that \( \lambda \) can be integral or half-integral if \( \eta \) is even (actually \( \alpha \) could be half-integral by considering genuine \( U(n) \) bundles \( \mathcal{V} \)).

We obtain the equation for the generation number of \( \tilde{\mathcal{V}} = V \otimes \mathcal{L} \oplus \mathcal{L}^{-4} \) with \( D = x \Sigma + \alpha \)

\[
N_{\text{gen}} = 4 \left[ \lambda - x(\lambda^2 - \frac{1}{4}) \right] \eta(\eta - 2c_1) + 40x(1 - 4x^2) - 4\alpha(\eta + c_1) - 60\alpha\alpha(\alpha - xc_1) \quad (7.1)
\]

One notes that \( N_{\text{gen}} \) is manifestly divisible by 4, except perhaps the first term. For \( n = 4 \) and \( \rho = 0 \) is \( \lambda \) either \( \mathbb{Z} + \frac{1}{2} \) or \( \lambda \in \mathbb{Z} \) with \( \eta \) even. It remains to discuss the term \( \eta(\eta - 2c_1) \). If \( \lambda \in \frac{1}{2} + \mathbb{Z} \) this term is divisible by two; if \( \lambda \in \mathbb{Z} \) as \( c_1 \) is even and \( \eta \equiv c_1 \mod 2 \) this term is divisible by 4. In total, also the first term is divisible by 4.

Therefore the physical generation number \( N_{\text{gen}}/2 \) downstairs on \( X/\mathbb{Z}_2 \) turns out to be even.

Furthermore one obtains five inequalities as conditions: one for the irreducibility of \( C \) (this is on \( F_0 \); when checking effectivity and irreducibility of \( C \) note that \( \eta \geq 0 \) implies on \( F_0 \) also \( \eta \cdot b \geq 0 \)); actually for \( C \) ample one gets a slightly sharper inequality; then two for the effectivity of \( W \) and two from the one-loop considerations, concerning positivity of \( \phi \) (where (7.5) is meant for \( x > 0 \); otherwise one has the reverse inequality) and of the gauge kinetic term:

\[
\eta \geq 2c_1 \quad (7.2)
\]

\[
w_B = 4c_1 - 2\eta + 10x(2\alpha - xc_1) \geq 0 \quad (7.3)
\]

\[
a_f = 48 - 2(\lambda^2 - \frac{1}{4})\eta(\eta - 2c_1) - 2\eta c_1 + 10\alpha^2 \geq 0 \quad (7.4)
\]

\[
\frac{1}{2}D \left[ \frac{3}{4}W - \frac{1}{2}c_2(X) \right] = (\alpha - xc_1) \left( \frac{3}{4}w_B - 3c_1 \right) + x(\frac{3}{4}a_f - 22) > 0 \quad (7.5)
\]

\[
\frac{1}{2}H_B \left[ \frac{3}{4}W - \frac{1}{2}c_2(X) \right] = \frac{3}{4} \left( -2\eta + 10x(2\alpha - xc_1) \right) H_B < 0 \quad (7.6)
\]

Therefore we have constructed invariant bundles on \( B \)-fibered Calabi-Yau spaces. Thereby we can get downstairs on \( X/\mathbb{Z}_2 \) a number of \( N_{\text{gen}}/2 \) net generations of chiral fermions of the Standard model (plus an additional right-handed neutrino).

\footnote{From (7.3) and (7.6) one may try to choose \( 0 \leq w_B \leq 4c_1 \) (with \( w_B \neq 4c_1 \)). But this is unnecessarily restrictive: (7.6) is satisfied for all ample \( H_B \) for \( w_B - 4c_1 \leq 0 \) (with \( w_B \neq 4c_1 \)); but if \( w_B - 4c_1 = (s,t) \) with already only one of them negative then one can find a certain \( H_B \) for which (7.6) holds.}
A Appendix

A.1 Equation of the spectral cover

Recall that in the $A$-model with elliptic curve $zy^2 = 4x^3 - g_2x - g_3$ in $\mathbb{P}^2 = \mathbb{P}_{1,1,1}$ with zero point $p = (0, 1, 0)$ the $(z) = l$ in $\mathbb{P}^2$ becomes $(z)|_E = 3p$ on $E$. To encode $n$ points on $E$ one chooses a homogeneous polynomial $w^{(\text{hom})}_{n/2}(x, y, z)$ of degree $n/2$. One realises that from its $3n/2$ zeroes on $E$ (after Bezout’s theorem) only $n$, say $q_i$, carry information as $n/2$ of them are always at $p$: for the rewriting $w^{(\text{hom})}_{n/2}(x, y, z) = z^{n/2}w_{n/2}^{\text{aff}}(x/z, y/z)$ shows manifestly $3n/2$ zeroes at $p$ from the $z$-power and $n$ poles at $p$ and $n$ zeroes at the $q_i$ (note that $x/z$ and $y/z$ have a pole at $p$ of order $-(1-3) = 2$ and $-(0-3) = 3$, resp., so the meromorphic function $w^{\text{aff}}|_E$ has that divisor). Concretely for $n = 4$

$$w^{(\text{hom})}(x, y, z) = a_4x^2 + a_3yz + a_2xz + a_0z^2 = z^2w^{\text{aff}}(\frac{x}{z}, \frac{y}{z})$$

(A.1)

This gives on $E$ for the divisor of $w^{(\text{hom})} = w$ resp. for the divisor of zeroes of $w^{\text{aff}}$

$$(w|_E) = \frac{n}{2}\sigma + \sum q_i \quad ; \quad (w^{\text{aff}}|_E)_0 = \sum q_i \quad (A.2)$$

Globally, as $(x, y, z)$ have $\mathcal{L} = K_B^{-1}$-weights $(2, 3, 0)$, one has $a_i \in H^0(B, \mathcal{O}(\eta - i\eta_1))$.

Now in the $B$-model with the elliptic curve in $\mathbb{P}_{1,2,1}$ one has the group zero $p_1 = (1, 1, 0)$ and the point $p_2 = (1, -1, 0)$; let $(z)|_E = p_1 + p_2 =: P$. The well-defined meromorphic functions $x/z$ and $y/z^2$ on $E$ have polar divisors $P$ and $2P$, respectively. For $n = 4$

$$w^{\text{aff}}_{n/2}(\frac{x}{z}, \frac{y}{z^2}) = \alpha_{20}(\frac{x}{z})^2 + \alpha_{02}\frac{y}{z^2} + \alpha_{10}\frac{x}{z} + \alpha_{00}$$

(A.3)

From the polar divisor of the meromorphic function $w^{\text{aff}}|_E$ one reads off its total divisor $(w^{\text{aff}}|_E) = 2P - \sum^4 q_i$. So the corresponding homogeneous polynomial $w^{(\text{hom})} = w$

$$w^{(\text{hom})}_{n/2}(x, y, z) = \alpha_{20}x^2 + \alpha_{02}y + \alpha_{10}xz + \alpha_{00}z^2 = z^2w^{\text{aff}}_{n/2}$$

(A.4)

has on $E$ just the divisor given by the four zeroes $q_i$ (as the double zeroes at the $p_i$ of the $z$-power cancel with the double poles there of $w^{\text{aff}}$), i.e.

$$(w|_E) = \sum q_i = (w^{\text{aff}}|_E)_0$$

(A.5)

(So this case is simpler than the $A$-model as no $n/2$ further zeroes at $p$ are carried along.)

Concerning the $\mathcal{L} = K_B^{-1}$-weights of the $\alpha_{ij}$, i.e. the transformation properties of the coefficient functions along the base of the fibration, $x, y, z$ have $\mathcal{L}$-weights $1, 2, 0$ (do not confuse them with their indicated $\mathbb{P}_{1,2,1}$ weights), so $\alpha_{ij} \in H^0\left(B, \mathcal{O}(\eta - (i + j)\eta_1)\right).$

---

\[8\text{The divisor } 2(\sigma_1 + \sigma_2) - \sum^4 q_i \text{ (in each fiber) of the meromorphic function } w/z^2 \text{ gives the relation } \sum^4 q_i = 2(\sigma_1 + \sigma_2) \text{ or } \sum^4(q_i - \sigma_1) = 2(\sigma_2 - \sigma_1) \text{ in the divisor class group, or } \sum^4 q_i = 2\sigma_2 \text{ in the group structure; so } \sum^4(2q_i - \sigma_2) = \sum^4 q_i^{\text{eff}} = 0, \text{ i.e. one has fiberwise an } SU(n)\text{-bundle, cf. section 4.3.}\]
A.2 The Kähler cone

Concerning the base surface $B = F_m$ note that the base and fiber classes $b$ and $f$ represent actual curves. The effective cone (non-negative linear combinations of classes of actual curves) is given by the condition $p \geq 0, q \geq 0$ on $\rho = pb + qf$; this we denote by $\rho \geq 0$. The Kähler cone $C_B$ of $B$ (where $\rho \in C_B$ means $\rho \zeta > 0$ for all actual curves of classes $\zeta$ or equivalently $\rho b > 0, \rho f > 0$) is given by $C_B = \{ t_1 b^+ + t_2 f | t_1 > 0 \}$ (with $b^+ = b + mf$).

For example on $F_2$ one has $c_1 \notin C_B$ as $c_1 b = 0$.

Let $J = x_1 \sigma_1 + x_2 \sigma_2 + H$ be an element in the Kähler cone $C_X$ ($H \in C_B$). Then demanding that its intersections with the curves $F$ and $\sigma_i \alpha$ are non-negative amounts to

$$x_1 + x_2 > 0$$  \hspace{1cm} (A.6)

$$H - x_i c_1 > 0$$  \hspace{1cm} (A.7)

Similarly intersecting $J^2$ with $\sigma_i$ and $\alpha$ and building also $J^3$ gives

$$(H - x_i c_1)^2 > 0$$  \hspace{1cm} (A.8)

$$\left( 2 \sum x_i H - \sum x_i^2 c_1 \right) \alpha > 0$$  \hspace{1cm} (A.9)

$$\sum x_i (H - x_i c_1)^2 + \left( 2 \sum x_i H - \sum x_i^2 c_1 \right) H > 0$$  \hspace{1cm} (A.10)

From this one gets the condition for $J$ to be ample (positive)

$$J = x_1 \sigma_1 + x_2 \sigma_2 + H \in C_X \iff x_1 + x_2 > 0 \ , \ H - x_i c_1 \in C_B$$  \hspace{1cm} (A.11)

So the condition for $C = \frac{n}{2} \Sigma + \eta$ to be ample (not only effective, cf. (3.4)) is

$$\eta - \frac{n}{2} c_1 \in C_B$$  \hspace{1cm} (A.12)

\[ A.9 \] is not independent as is clear for $x_1$ and $x_2$ individually non-negative, and follows in general with \[ A.9 \] (as the left hand side of \[ A.10 \] is $\sum x_i (3H^2 - 3x_i Hc_1 + 8x_i^2) \geq 8 \sum x_i^3$ using \[ A.7 \] for $\alpha = H$).

\[ A.9 \] follows from \[ A.7 \], giving $\left( \sum x_i H - \sum x_i^2 c_1 \right) \alpha \geq 0$, with \[ A.6 \], giving $\sum x_i H \alpha \geq 0$.
