CaPUB1, a Hot Pepper U-box E3 Ubiquitin Ligase, Confers Enhanced Cold Stress Tolerance and Decreased Drought Stress Tolerance in Transgenic Rice (Oryza sativa L.)

Hye Jo Min1, Ye Jin Jung1, Bin Goo Kang1, and Woo Taek Kim1,*

INTRODUCTION

Rice is a staple crop worldwide and a typical monocot model plant. Like other plant species, rice is faced with a variety of environmental stresses throughout its life cycle. Drought is a major abiotic stress responsible for the reduction of rice productivity worldwide. In addition, rice is often exposed to unfavorable temperatures below 20°C in the sub-tropical and high-elevation zones, leading to chilling injury. These stresses cause stunted growth, weakened photosynthetic ability, reduced tillering, delayed heading, and greatly reduced agricultural production (Benjamin and Nielsen, 2006; Kim and Tai, 2011; Mackill and Lei, 1997; Praba et al., 2009).

Higher plants have developed molecular and physiological response mechanisms to tolerate such detrimental conditions. Under stress conditions, a series of signaling pathways regulate gene expression to produce various kinds of defensive proteins and molecules. Diverse sets of genes are induced under both drought and cold stress, but a subset of genes respond either only to dehydration or only to low temperature (Shinozaki et al., 2000). The presence of these suggests that there is cross-talk between drought and cold stress signaling pathways.

The ubiquitin (Ub)-mediated post-translational modification of proteins regulates numerous cellular processes, including cell cycle progression, environmental stress responses, and hormone signaling. AtPUB18/AtPUB19 and AtPUB22/AtPUB23 function as ABA-dependent and ABA-independent negative regulators in drought responses, respectively (Bergler and Hoth, 2011; Cho et al., 2008; Liu et al., 2011; Seo et al., 2012). In addition, three homologous AtPUB22, AtPUB23, and AtPUB24 E3 ligases were proposed as negative regulators of plant defense responses to pathogen infection (Stegmann et al., 2012; Trujillo et al., 2008). Rice OsSPL11 is a negative regulator in the pathogenic defense reaction and HR-associated cell death (Zeng et al., 2004). OsPUB15 plays a role in reducing cellular oxidative stress and cell death during seedling establishment in rice (Park et al., 2011).

Abiotic stresses such as drought and low temperature critically restrict plant growth, reproduction, and productivity. Higher plants have developed various defense strategies against these unfavorable conditions. CaPUB1 (Capsicum annuum Putative U-box protein 1) is a hot pepper U-box E3 Ub ligase. Transgenic Arabidopsis plants that constitutively expressed CaPUB1 exhibited drought-sensitive phenotypes, suggesting that it functions as a negative regulator of the drought stress response. In this study, CaPUB1 was over-expressed in rice (Oryza sativa L.), and the phenotypic properties of transgenic rice plants were examined in terms of their drought and cold stress tolerance. Ubi:CaPUB1 T3 transgenic rice plants displayed phenotypes hypersensitive to dehydration, suggesting that its role in the negative regulation of drought stress response is conserved in dicot Arabidopsis and monocot rice plants. In contrast, Ubi:CaPUB1 progeny exhibited phenotypes markedly tolerant to prolonged low temperature (4°C) treatment, compared to those of wild-type plants, as determined by survival rates, electrolyte leakage, and total chlorophyll content. Cold stress-induced marker genes, including DREB1A, DREB1B, DREB1C, and Cytochrome P450, were more up-regulated by cold treatment in Ubi:CaPUB1 plants than in wild-type plants. These results suggest that CaPUB1 serves as both a negative regulator of the drought stress response and a positive regulator of the cold stress response in transgenic rice plants. This raises the possibility that CaPUB1 participates in the cross-talk between drought and low-temperature signaling pathways.

Keywords: cold stress, cross-talk in stress response, drought stress, transgenic rice (Oryza sativa) plants, u-box E3 Ub ligase
CaPUB1 (Capsicum annuum Putative U-box protein 1) is a hot pepper U-box E3 Ub ligase (Cho et al., 2006). The CaPUB1 gene activity was enhanced by environmental stresses, including drought and cold, in hot pepper seedlings. Transgenic Arabidopsis plants that constitutively expressing CaPUB1 exhibited drought-sensitive phenotypes, suggesting that its function is to act as a negative regulator of the drought stress response.

In this report, CaPUB1 was over-expressed in rice (Oryza sativa L.) and the phenotypic properties of transgenic rice plants were examined in terms of their drought and cold stress tolerance. Ubi:CaPUB1 transgenic rice plants exhibited hypersensitive to water deficit, implying that its function in drought stress responses is conserved in rice and Arabidopsis. In contrast, CaPUB1-overexpressing rice plants displayed phenotypes markedly more tolerant to prolonged low temperature treatment than those of wild-type plants. These results suggest that CaPUB1 plays an opposite role in the response of rice to drought and cold stress. These introduced the possibility that CaPUB1 is involved in the cross-talk between drought and cold stress responses.

MATERIALS AND METHODS

Plant materials and growth conditions

Dry rice (Oryza sativa L. japonica variety 'Dong-jin') seeds were sequentially washed with 70% ethanol and distilled water. Rice seeds were sterilized with 0.4% NaClO solution for 30 min, rinsed with sterilized water, and germinated on half-strength Murashige and Skoog (MS) medium containing vitamins (Duchefa Biochemie, The Netherlands), 3% sucrose, and 0.7% phytoagar. Rice seedlings were grown for 10 days at 28°C under long-day conditions (16 h light/8 h dark), and then transplanted to soil in a growth chamber or greenhouse.

Generation of Ubi:CaPUB1 transgenic rice plants

To generate CaPUB1-overexpressing transgenic rice plants, the full-length CaPUB1 was introduced into the pGA2897 vector. The resulting binary vector was transformed into Agrobacterium tumefaciens strain LBA4404 via electroporation, as described by Shaw (1995), with some modifications. Wild-type embryonic calli were co-cultivated with Agrobacterium cells containing the Ubi:CaPUB1 construct via the standard transformation method, as recently described by Zeng et al. (2014). The transformed callus tissues were selected based on their hygromycin resistance. Transgenic T0 plants were regenerated from selected calli as described by Byun et al. (2015), and T3 plants were used for the phenotypic analysis.

Genomic DNA extraction and genomic Southern blot analysis

To identify independent lines of Ubi:CaPUB1 transgenic plants, a genomic Southern blot analysis was performed. Total genomic DNA was extracted from leaves using CTAB solution (2% CTAB, 2% PVP-40, 1.4 M NaCl, 100 mM Tris-HCl, pH 8.0, and 20 mM EDTA). Total DNAs from wild-type and transgenic plants were digested with EcoRI restriction enzyme (Roche, USA), precipitated, and separated by electrophoresis on 0.8% agarose gels. The gels were serially soaked in depurination, denaturation, and neutralization buffer. DNA on the gel was transferred to a nylon membrane (GE healthcare, Sweden) via the capillary transfer method. The DNA gel blot was hybridized with 32P-labeled hygromycin B phosphotransferase (HPT) probe under high-stringency hybridization and washing conditions (65°C). The autoradiography signals were visualized using the Bio-Imaging Analyzer (BAS2500; Fuji Film, Japan).

RT-PCR and quantitative RT-PCR analysis

Total RNA was extracted from various tissues from 2-week-old and 2-month-old mature wild-type and Ubi:CaPUB1 transgenic rice plants using Easy Spin Plant Total RNA Extraction kits (iNTRON Biotechnology, Korea) according to the manufacturer’s protocol. Single-strand cDNA was synthesized from 2 μg of total RNA with TOPscript Reverse Transcriptase (Enzynomics, Daejeon, Korea) and oligo (dT) primers as described by Han et
For RT-PCR analysis, CaPUB1 and OsUBQ10 gene were amplified from synthesized cDNA product using a gene-specific primer set. Real-time qRT-PCR was performed using an IQ5 light cycler (Bio-Rad, USA) with SYBR Green Premix Ex TaqII (Takara, Japan), as described previously (Shen et al., 2014). The OsACTIN was used as an internal control to normalize the data. The primer sets used in this study are listed in Table 1.

Stress treatments of rice plants
Wild-type and Ubi:CaPUB1 transgenic rice plants were grown for 6 weeks under normal growth conditions and subjected to drought or cold stress. To examine the water stress responses, 10-day-old wild-type and Ubi:CaPUB1 lines were transplanted into the same pot and grown in the growth chamber. Light-grown, 6-week-old plants were further grown without irrigation for 9 days, and recovered by re-watering. To investigate the effect of CaPUB1 on cold stress tolerance, 6-week-old plants were transferred to a growth chamber maintained at 4°C for 6 days, after which plants were recovered at 28°C.

Analysis of drought and cold stress phenotypes of wild-type and Ubi:CaPUB1 transgenic plants
For water loss rate measurement of wild-type and Ubi:CaPUB1 transgenic lines, the cut aerial parts of 5-week-old plants were incubated at 25°C under dim light and their weights were estimated at various time points. The water loss rates were expressed as a percentage of initial fresh weights as described previously (Cho et al., 2011).

Total chlorophyll (chlorophyll a + chlorophyll b) was extracted from drought and cold stress-treated wild-type and Ubi:CaPUB1 transgenic rice leaves as previously described (Lichtenthaler, 1987) with slight modifications. Chlorophyll content was estimated with a spectrophotometer (model DU800; Beckman Coulter). Chlorophyll a and chlorophyll b were measured at 664.2 nm and 648.6 nm, respectively. Total chlorophyll content was calculated using the following formula: chlorophyll a + chlorophyll b (mg/g DW) = 8.1 × (5.24 A_{648.6} + 22.24 A_{664.2})/DW.

An electrolyte leakage assay was conducted with the leaves of 5-week-old wild-type and Ubi:CaPUB1 rice plants after 7 days of 4°C treatment. The conductivity of each sample was estimated before and after autoclaving with a conductivity meter (Orion Star A212, Thermo Scientific, USA).

RESULTS
Generation of Ubi:CaPUB1 transgenic rice plants
To investigate the role of CaPUB1 in the environmental stress responses of crop plants, CaPUB1 was constitutively expressed in rice under the control of the maize ubiquitin promoter (Ubi) via the Agrobacterium-mediated transformation method (Fig. 1A). The T0 transgenic plants regenerated from callus tissue were isolated according to their hygromycin resistance (Fig. 1A). Based on the semi-quantitative RT-PCR analysis, the mRNA level of CaPUB1 was markedly enhanced in transgenic (lines #1 and #2) rice plants (Fig. 1B). The genomic Southern blot analysis indicated that these CaPUB1-overexpressing transgenic plants were independent lines and both possessed a single copy of the transgene (Fig. 1C). Next, we examined the developmental phenotypes of T3 Ubi:CaPUB1 transgenic lines and compared them to those of wild-type plants. There were no detectable phenotypic differences between the transgenic and wild-type rice plants under normal growth conditions (Fig. 1D). These T3 CaPUB1-overexpressing transgenic plants were used for the subsequent phenotypic analysis.
CaPUB1 Confers Cold Stress Tolerance in Rice
Hye Jo Min et al.

Over-expression of CaPUB1 in rice decreases tolerance to drought stress

To elucidate the effect of CaPUB1 overexpression on abiotic stress responses in rice, we assessed drought stress tolerance. Light-grown, 6-week-old wild-type and transgenic (lines #1 and #2) plants were sown in the same pot and grown for 9 days without irrigation. These water-stressed plants were then irrigated normally. As shown in Fig. 2A, wild-type plants exhibited 76.3-80.4% survival rates after re-watering. However, only 14.6% of Ubi:CaPUB1 line #1 and 15.9% of Ub:CaPUB1 line #2 survived.

Consistent with survival rates, after drought stress the total chlorophyll content of wild-type leaves was much higher than that of CaPUB1-overexpressing progeny. Wild-type and Ubi:CaPUB1 leaves contained very similar amounts of chlorophyll a + chlorophyll b (8.5 ± 0.2 mg/g DW) under normal growth conditions (Fig. 2B). The chlorophyll content of detached wild-type leaves was reduced to 4.6 ± 0.2 mg/g DW after drought stress. However, Ub:CaPUB1 transgenic lines #1 and #2 exhibited pale green and bleached leaves, and their total chlorophyll contents were only 0.9 ± 0.1 mg/g DW and 0.8 ± 0.1 mg/g DW, respectively, after drought stress (Fig. 2B).

In addition, during dehydration CaPUB1-overexpressing rice plants lost water more rapidly than wild-type plants. The aerial parts of 5-week-old wild-type and transgenic rice plants were detached, incubated for 0–5 h at room temperature, and their water loss rates were monitored. After 1 h incubation, the aboveground parts of the wild-type and Ubi:CaPUB1 (lines #1 and #2) plants retained approximately 84% and 80-81% of their fresh weights, respectively (Fig. 2C). After 4 h incubation, wild-type leaves lost approximately 45% of their starting weights, while those of transgenic lines lost almost 50% of their fresh weights (Fig. 2C). These results indicate that more rapid water loss occurred in Ubi:CaPUB1 transgenic lines than in wild-type rice plants. Taken together, the over-expression of CaPUB1 decreased drought-stress tolerance in rice, suggesting that negative role played by U-box E3 ligase CaPUB1 in response to drought stress is conserved in Arabidopsis (Cho et al., 2006) and rice.

Ubi:CaPUB1 transgenic rice plants are more tolerant to cold stress than wild-type plants

Because the CaPUB1 transcript levels were elevated by cold temperature (4°C) as well as dehydration (Cho et al., 2006), we next examined whether the constitutive expression of CaPUB1 alters response to cold stress in rice. Both wild-type and CaPUB1-overexpressors were grown at 28°C for 6-weeks and subjected to cold stress (4°C) for 6 days. Then, they were transferred to a 28°C growth chamber and their growth was
observed. After the cold treatment, all wild-type plants examined wilted, lost their chlorophyll, were unable to grow, and died, with survival rates of 0-2.8%. In contrast, most of the Ubi:CaPUB1 transgenic rice plants displayed a healthy morphology and resumed growth. The survival rates of Ubi:CaPUB1 transgenic lines #1 and #2 were 60.9% and 64.5%, respectively (Fig. 3A).

These results were further validated by measuring the total chlorophyll content. Both cold stress-treated wild-type and transgenic plants were allowed to recover for 7 days, after which their leaf chlorophyll contents were determined. Most wild-type leaves lost their green color after stress treatment and contained 1.2 ± 0.4 mg/g DW of total chlorophyll. However, Ubi:CaPUB1 leaves retained 5.5 ± 0.7 mg/g DW (line #1) and 5.1 ± 0.6 mg/g DW (line #2) of chlorophyll a + chlorophyll b, respectively after low temperature treatment (Fig. 3B).

Subsequently, the mature leaves of 5-week-old wild-type and CaPUB1-overexpressing plants were exposed to 4°C for 7 days, after which their electrolyte leakage was determined. The results revealed that after cold treatment, the Ubi:CaPUB1 leaves displayed lower conductivity means (8.8% for lines #1 and #2) than wild-type leaves (14.7%) (Fig. 3C). These results suggest that Ubi:CaPUB1 transgenic rice plants were more tolerant of cold stress (4°C) than wild-type plants.

Cold stress-induced marker genes were more enhanced in Ubi:CaPUB1 transgenic plants than in wild-type plants under low temperature conditions

To investigate whether CaPUB1 affects the expression profiles of cold-stress related genes in rice, we conducted real-time
quantitative RT-PCR (qRT-PCR). Both wild-type and transgenic lines were subjected to cold stress (4°C) for 0 or 24 h, after which total RNA was isolated from the shoot tissue. The expression patterns of cold stress-induced marker genes, including DREB1A, DREB1B, DREB1C, and Cytochrome P450, were observed by qRT-PCR using gene-specific primer sets (Table 1). The results in Figure 4 demonstrate that there was no significant difference between the transcripts levels of these four marker genes in wild-type and transgenic lines under normal growth conditions. However, after cold-stress treatment, all four marker genes displayed higher induction level in CaPUB1-overexpressors than in wild-type plants. These results suggest that the cold stress-tolerant phenotypes of the Ubi:CaPUB1 plants were correlated with increased levels of cold stress-induced gene expression.

**DISCUSSION**

CaPUB1 was previously identified as an abiotic stress-induced gene that encodes a U-box E3 Ub ligase in hot pepper (Capsicum annuum c.v. pukang) (Cho et al., 2006). Ectopic expression of CaPUB1 in the dicot model plant Arabidopsis results in phenotypes that exhibit hyper-sensitive responses to dehydration, suggesting that it plays a negative role in the drought stress response (Cho et al., 2006). In this study, CaPUB1 was constitutively overexpressed in rice, a monocot model plant, and CaPUB1-overexpressing transgenic plants (Ubi:CaPUB1) were characterized in terms of their drought and cold stress responses. The results reveal that Ubi:CaPUB1 lines are more sensitive to water deficit than wild-type rice plants, as determined by survival rates, total leaf chlorophyll content, and the rate of water loss from above-ground parts (Fig. 2). These results are consistent with the drought-sensitive phenotypes of CaPUB1-overexpressing Arabidopsis plants, implying that the role of the molecule as a negative regulator of the response to drought is conserved in both dicot Arabidopsis and monocot rice plants.

In contrast to drought stress responses, the Ubi:CaPUB1 transgenic plants exhibited phenotypes highly tolerant to low temperature stress. After 6 days of exposure to 4°C, the CaPUB1-overexpressing lines displayed healthy green leaves with larger amounts of total chlorophyll and lower rates of electrolyte leakage, along with over 60% survival rates, as compared to wild type plants (0-2.8% survival rates) (Fig. 3). Thus, during the extended low temperature treatment Ubi:CaPUB1 plants appeared to retain a higher level of photosynthetic ability and experience less membrane disruption than wild-type plants. Based on these results, we concluded that the overexpression of CaPUB1 conferred tolerance to cold stress on transgenic rice plants.

qRT-PCR analysis showed that after cold treatment, the expression levels of OsDREB1A/CBF3, OsDREB1/CBF1, and OsDREB1/CBF2 were much higher in Ubi:CaPUB1 transgenic lines than in wild-type plants (Fig. 4). These transcription factor genes are induced during an early stage of the cold response, in order to activate diverse sets of cold-responsive genes in rice (Dubouzet et al., 2003; Itô et al., 2006; Su et al., 2010). A number of studies proposed that DREBs serve as a major regulatory network acting in response to low temperature conditions (Agarwal et al., 2013; Thomashow, 2010; Zhang et al., 2013). The over-expression of DREBs often resulted in dwarf phenotypes even under normal growth conditions (Dubouzet et al., 2003; Gilmour et al., 2000; Xu et al., 2011). It is worth noting that Ubi:CaPUB1 transgenic rice plants did not exhibit detectable growth retardation (Fig. 1D). This could be due to that, in contrast to constitutive expression, the basal levels of OsDREB1A/CBF3, OsDREB1/CBF1, and OsDREB1/CBF2 were very low under normal conditions, but were more up-regulated by the cold treatment in Ubi:CaPUB1 plants than in wild-type plants.

In addition, Ubi:CaPUB1 showed the enhanced expression level of Cytochrome P450 (CYP709C9) after 4°C treatment. Although the roles of Cytochrome P450 (CYP709C9) have not been clearly understood, it was previously reported that it could function as a potential marker gene for oxidative stress tolerance in rice (Liu et al., 2010). Consistent with this notion, Cytochrome P450 (CYP709C9) was induced by exposure to low temperatures, methyl viologen, and arsenate treatments (Su et al., 2010; Tripathi et al., 2012). Furthermore, Cytochrome P450 (CYP709C9) was down-regulated in Ubi:OsSPX1-antisense transgenic rice plants that displayed phenotypes hypersensitive
to cold stress (Wang et al., 2013).

Thus, we speculate that CaPUB1 increases the expression of DREB cold-responsive transcription factors and cytochrome P450 by an as-yet unidentified mechanism, which, in turn, confers tolerance to cold stress on transgenic rice plants. Because CaPUB1 is a U-box E3 Ub ligase and possesses neither a DNA binding domain nor a transcription activator domain, we ruled out the possibility that CaPUB1 directly binds to the upstream regions of OsDREBs and Cytochrome P450 and induces them. Alternatively, we hypothesized that CaPUB1 ubiquitinates and triggers the proteasome-dependent degradation of a negative factor that inhibits the expression of cold-responsive genes.

**Ub:CaPUB1** transgenic rice plants displayed similar morphological phenotypes as compared to wild-type rice under normal growth conditions (Fig. 1D). It was previously reported that over-expression of CaPUB1 in Arabidopsis caused enhanced vegetative growth and early bolting (Cho et al., 2006). These results suggest that ectopic expression of CaPUB1 may exert different effects on growths of monocot rice and dicot Arabidopsis plants.

A database search revealed three potential CaPUB1 orthologs, OsPUB31, OsPUB32, and OsPUB33 with 41%, 43%, and 44% amino-acid identities, respectively, in rice (Supplementary Fig. S1). Cellular functions of these three rice U-box E3 homologs are not currently unraveled. Elucidation of the roles of rice U-box E3 Ub ligases will provide more detailed information on responses to drought and cold stresses in crop plants.

The over-expression of CaPUB1 decreased tolerance to water deficit, but enhanced tolerance to cold stress in rice (Figs. 2 and 3). This raises the possibility that CaPUB1 is involved in the cross-talk of the signaling pathways of two different environmental stresses: drought and cold. Although a number of studies proposed that diverse E3 Ub ligases play regulatory roles in response to abiotic stresses, understanding their roles in the cross-talk between different stress responses is still rudimentary. In Arabidopsis, the suppression of AATL78, a RING-type E3 Ub ligase, resulted in increased cold tolerance, but decreased drought tolerance, suggesting that it plays a role in the cross-talk between the drought and cold stress responses (Kim and Kim, 2013). Thus, additional experiments are required to elucidate the detailed mechanisms, by which CaPUB1 plays an opposite role in the drought stress and cold stress responses of transgenic rice plants.

In conclusion, our data suggest that the constitutive expression of a U-box E3 ubiquitin ligase CaPUB1 increases tolerance to cold stress and decreases tolerance to drought stress in rice, a monocot model crop plant. Our study also suggests that CaPUB1 could be utilized as a genetic material to investigate the novel regulatory module for two environmental stresses, drought and low temperature. In addition, enhanced tolerance to cold stress of CaPUB1 overexpressing rice plants may have an advantage for preventing decrease in rice production caused by chilling injury during their vegetative stage in temperate regions.

Stegmann, M., Anderson, R.G., Ichimura, K., Pecenkova, T., Reuter, P., Žárský, V., McDowell, J.M., Shirasu, K., and Trujillo, M. (2012). The ubiquitin ligase PUB22 targets a subunit of the exocyst complex required for PAMP-triggered responses in Arabidopsis. Plant Cell 24, 4703-4716

Su, C.F., Wang, Y.C., Hsieh, T.H., Tseng, T.H., Chen, H., and Chu, C. (2009). Overexpression of a rice OsDREB1F gene increases salt, drought, and low temperature tolerance in both Arabidopsis and rice. Plant Mol. Biol. 67, 589-602

Xu, M., Li, L., Fan, Y., Wan, J., and Wang, L. (2011). ZmCBF3 overexpression improves tolerance to abiotic stress in transgenic rice (Oryza sativa) without yield penalty. Plant Cell Rep. 30, 1949-1957

Yang, C.W., González-Lamothe, R., Ewan, R.A., Rowland, O., Yoshioka, H., Shenton, M., Ye, H., O’Donnell, E., Jones, J.D., and Sadanandom, A. (2006). The E3 ubiquitin ligase activity of Arabidopsis PLANT U-BOX17 and its functional tobacco homolog ACRE276 are required for cell death and defense. Plant Cell 18, 1084-1098

Zeng, L.R., Qu, S., Bordeos, A., Yang, C., Baracidan, M., Yan, H., Xie, Q., Nahm, B.H., Leung, H., and Wang, G.L. (2004). Spotted leaf11, a negative regulator of plant cell death and defense, encodes a U-box/armadillo repeat protein endowed with E3 ubiquitin ligase activity. Plant Physiol. 135, 1458-1501

Zeng, D-E., Hou, P., Xiao, F., and Liu, Y. (2014). Overexpression of a novel RING-H2 finger protein gene, OsRHP1, enhances drought and salt tolerance in rice (Oryza sativa L.). J. Plant Biol. 57, 357-365

Zhang, Q., Jiang, N., Wang, G.L., Hong, Y., and Wang, Z. (2013). Advances in understanding cold sensing and the cold-responsive network in rice. Adv. Crop Sci. Tech. 1, 104
