The Fisher-Hartwig Formula and Generalized Entropies in XY Spin Chain

Received: date / Accepted: date

Abstract Toeplitz matrices have applications to different problems of statistical mechanics. Recently it was used for calculation of entanglement entropy in exactly solvable models including spin chains. We use Fisher-Hartwig formula to calculate entanglement entropy [as well as Rényi entropy] of large block of spins in the ground state of XY spin chain. In the end of the paper we announce our recent results [with F. Franchini and L. A. Takhtajan] on spectrum of density matrix of the block of spins.

Keywords Toeplitz determinant · Fisher-Hartwig formula · entanglement · spin chain

1 Introduction

We study von Neumann entropy and Rényi entropy of spin chains by means of the Fisher-Hartwig formula. The concept of entanglement was introduced Schrödinger in 1935 in the course of developing the famous ‘cat paradox’, see [68]. Recently it became important as a resource for quantum control, which is central for quantum device building, including quantum computers (it is a primary resource for information processing). Entropy of a subsystem as a measure of entanglement was introduced in [13]. We study spin chains with unique ground state. Von Neumann entropy (and Rényi entropy) of the
whole ground state is zero, but it is positive for a subsystem [block of spins]. In order to define entanglement entropy one has to introduce reduced density matrix. The reduced density matrix was first introduced by P. A. M. Dirac in 1930, see [27].

We calculate the entropy of a block of \( L \) continuous spins in the ground state of a Hamiltonian. We can think that the ground state is a bipartite system \( |GS\rangle = |A\rangle\langle B| \), where we call the block by subsystem \( A \) and the rest of the ground state by subsystem \( B \). The density matrix of the ground state is \( \rho_{AB} = |GS\rangle\langle GS| \), and the density matrix of the block of \( L \) neighboring spins [subsystem \( A \)] is \( \rho_A = \text{Tr}_B (\rho_{AB}) \), where we trace out all degrees of freedom outside the block. The von Neumann entropy of the block is

\[
S(\rho_A) = -\text{Tr}_A (\rho_A \ln \rho_A),
\]

which measures how much the block is entangled with the rest of the ground state. On the other hand, the Rényi entropy \( S(\rho_A, \alpha) \) is defined as

\[
S(\rho_A, \alpha) = \frac{1}{1-\alpha} \ln \text{Tr}_A (\rho_A^\alpha), \quad \text{and} \quad \alpha > 0,
\]

here \( \alpha \) is a parameter. Rényi entropy [67] is important in information theory. The Rényi entropy turns into von Neumann entropy at \( \alpha \to 1 \). Knowledge of the Rényi entropy at arbitrary \( \alpha \) permits evaluation of spectrum of the density matrix. Our main example is \( XY \) spin chain.

Toeplitz matrix \( T_L[\Phi] \) is said to be expressed in terms of generating function \( \Phi(\theta) \) (which is called symbol in mathematical literature):

\[
T_L[\Phi] = (\Phi_{i-j}), \quad i, j = 1, \ldots, L - 1
\]

where

\[
\Phi_k = \frac{1}{2\pi} \int_0^{2\pi} \Phi(\theta) e^{-ik\theta} d\theta
\]

is the \( k \)-th Fourier coefficient of generating function \( \Phi(\theta) \). The generating function \( \Phi(\theta) \) can be type of \( N \times N \) matrix and \( T_L[\Phi] \) is a \( NL \times NL \) matrix for such case. One of the central objects in the study of Toeplitz matrix \( T_L[\Phi] \) is its determinant, which we will denote as \( D_L[\Phi] \),

\[
D_L[\Phi] := \det T_L[\Phi].
\]

Starting with Onsager's celebrated solution of the two-dimensional Ising model in the 1940's, Toeplitz determinants play an increasingly central role in modern mathematical physics. We refer the reader to the book [60], and to survey [59] as for comprehensive sources of the classical results and the history concerning the use of Toeplitz determinants in statistical mechanics.

Another important areas of applications of Toeplitz determinants are random matrices and combinatorics. We refer the readers to the works [71,4,35] for the basic results and for the historic reviews.

Given a generating function \( \Phi(\theta) \), a principal question is the evaluation of the large \( L \) behavior of the Toeplitz determinant \( D_L[\Phi] \). The pioneering works on the asymptotic analysis of Toeplitz determinants were done by
Szegő (regular symbol) and by Fisher and Hartwig (singular symbol). These results have been used in the study of spin correlation in two-dimensional Ising model in the classical works of Wu and McCoy, see for example [60] and since then by many other researchers and for a various generating functions.

The main focus of the majority of works in the area has been, so far, the study of spin correlations. The key objects of the analysis have been the relevant correlation functions of the local operators. In this paper, we discuss yet another, more recent application of the asymptotic analysis of Toeplitz determinants in the theory of quantum spin models. Instead of the local operators, these applications are concerned with the important nonlocal objects appearing in spin chains in connection to their suggested use in quantum informatics [52]. Indeed, we shall survey some of the recent results concerning the quantum entanglement. We will consider the two applications - the entanglement in the XX model and in the XY model. The first one is related to a singular scalar generating function, while the second one deals with a regular but \((2 \times 2)\) matrix generating function.

We begin with the brief review of the history and some of the most recent results concerning the asymptotic analysis of Toeplitz determinants.

The plan of the paper is:

In the second section we discuss the asymptotical expression of the determinant of a large Toeplitz matrix. The section is divided into subsections. Subsection 2.2 is devoted to block Toeplitz determinants.

Third section is devoted to XY spin chain. In subsection 3.1 we remind derivation of determinant representation of entropy of a block of spins in the ground state. Isotropic case, i.e. the XX model, is considered in 3.2. For anisotropic case we have to use block Toeplitz matrices.

In section 4 we derive asymptotic expression of entropy of large block of spins in isotropic case: the leading logarithmic term and sub-leading corrections.

In section 5 we derive asymptotic expression of von Neuman entropy of large block of spins in anisotropic case. In the case of XY spin chain the entropy has a limit. We calculate the limit.

In section 6 we calculate limiting expression for Renyi entropy of large block of spins in XY spin chain.

In section 7 we derive the spectrum of the limiting density matrix from Renyi entropy. We prove that the spectrum is exact geometric sequence, see Eq. 117 and Eq. 124. We also calculate the degeneracy of individual eigenvalues, see f Eq. 126.

The content of sections 4 - 7 is based on the works [45,39,40,33,34].

In section 8 we formulate open problems.

2 Szegő and Fisher-Hartwig Asymptotics

Throughout the paper we will follow the usual, in the theory and applications of Toeplitz determinants, convention to denote the argument of the functions on the unite circle either as \(\theta\) or as \(z\), \(z = e^{i\theta}\), i.e. we will always assume the
notational identity,
\[ f(z) \equiv f(\theta), \quad z = e^{i\theta}, \quad \theta \in [0, 2\pi). \]

We first consider the case of scalar generating function, i.e. \( N = 1 \). We shall also use for this case the low case symbol \( \phi \) instead of \( \Phi \).

2.1 Szegő and Fisher-Hartwig asymptotics in the case of scalar symbols

In this subsection we review the basic mathematical facts concerning the asymptotics of Toeplitz determinants \( D_L[\phi] \) with scalar generation functions \( \phi(z) \).

The large \( L \) asymptotic behavior of \( D_L[\phi] \) depends significantly on the analytical properties of the generating function \( \phi(\theta) \). In the case of the smooth enough functions \( \phi(\theta) \), the behavior is exponential and its leading and the pre-exponential terms are given by the following classical result of Szegő, known as the strong Szegő limit theorem.

**Theorem 1.** Suppose that the generation function \( \phi(\theta) \) satisfies the conditions,

1. \( \phi(\theta) \neq 0 \), for all \( \theta \in [0, 2\pi) \).
2. index \( \phi(\theta) \equiv \arg \phi(2\pi) - \arg \phi(0) = 0 \)
3. \( \sum_{k=-\infty}^{\infty} |V_k| + \sum_{k=-\infty}^{\infty} |k||V_k|^2 < \infty \), where \( V_k \) are the Fourier coefficients of the function,

\[ V(\theta) := \ln \phi(\theta), \quad (6) \]

that is,

\[ V(z) = \sum_{k=-\infty}^{\infty} V_k z^k, \quad V_k = \frac{1}{2\pi} \int_{0}^{2\pi} V(\theta)e^{-ki\theta} d\theta. \quad (7) \]

Then,

\[ D_L[\phi] \sim E_{Sz}[\phi] \exp\left(LV_0\right), \quad L \to \infty, \quad (8) \]

where the pre-exponential factor, \( E_{Sz}[\phi] \), is given by the equation\(^1\),

\[ E_{Sz}[\phi] = \exp\left(\sum_{k=1}^{\infty} kV_k V_{-k}\right). \quad (9) \]

Conditions (1) and (2) on the symbol \( \phi(\theta) \) ensure that the function \( V(z) \) is a well defined function on the unit circle. Condition (3) is a smoothness

\(^1\) It is this equation which is responsible for the term “strong Szegő theorem”. Szegő’s first result, i.e. Szegő limit theorem produced the asymptotics of the determinant \( D_L[\phi] \) up to an undetermined multiplicative constant.
condition\(^2\). It is certainly satisfied by the differentiable functions and is not satisfied by the functions having root and jump singularities. In the context of Toeplitz matrices, this type of singularities is usually called the *Fisher-Hartwig singularities*. The general form of the symbol \(\phi(z)\) which has \(m\), \(m = 0, 1, 2, \ldots\) fixed Fisher-Hartwig singularities is given by the equation\(^3\),

\[
\phi(z) = e^{V(z)} z^{\sum_{j=0}^m \beta_j} \prod_{j=0}^m |z-z_j|^{2\alpha_j} g_{z_j,\beta_j}(z) z^{-\beta_j}, \quad z = e^{i\theta}, \quad \theta \in [0, 2\pi),
\]

(10)

where

\[
z_j = e^{i\theta_j}, \quad j = 0, \ldots, m, \quad 0 = \theta_0 < \theta_1 < \cdots < \theta_m < 2\pi; \quad (11)
\]

\[
g_{z_j,\beta_j}(z) \equiv g_{\beta_j}(z) = \begin{cases} e^{i\pi\beta_j} & 0 \leq \arg z < \theta_j, \\ e^{-i\pi\beta_j} & \theta_j \leq \arg z < 2\pi, \end{cases} \quad (12)
\]

\[
\Re \alpha_j > -1/2, \quad \beta_j \in \mathbb{C}, \quad j = 0, \ldots, m, \quad (13)
\]

and \(V(z)\) is a sufficiently smooth function on the unit circle so that the first factor of the right hand side of equation (10) represents the “Szego part” of the symbol. The condition on \(\alpha_j\) insures integrability. As it has already been mentioned before, a single Fisher-Hartwig singularity at \(z_j\) consists of a root-type singularity

\[
|z - z_j|^{2\alpha_j} = \left| 2 \sin \frac{\theta - \theta_j}{2} \right|^{2\alpha_j} \quad (14)
\]

and a jump \(g_{\beta_j}(z)\). A point \(z_j, j = 1, \ldots, m\) is included in (11) if and only if either \(\alpha_j \neq 0\) or \(\beta_j \neq 0\) (or both); in contrast, we always fix \(z_0 = 1\) even if \(\alpha_0 = \beta_0 = 0\) (note that \(g_{\beta_0}(z) = e^{-i\pi\beta_0}\)). Observe that for each \(j = 1, \ldots, m\), \(z^{\beta_j} g_{\beta_j}(z)\) is continuous at \(z = 1\), and so for each \(j\) each “beta” singularity produces a jump only at the point \(z_j\).

In 1968, M. Fisher and R. Hartwig \cite{31} suggested a formula for the leading term of the asymptotic behavior for the Toeplitz determinant generated by the symbol (10)\(^4\). The principal insight of Fisher and Hartwig was the observation that the singularities of the symbol yield the appearance of the

\(^2\) In \cite{70}, Szegő proved this theorem under a somewhat stronger smoothness assumption on the symbol; namely, he assumed that the symbol is positive, and that the symbol and its derivative are Lipschitz functions. It took a substantial period of time and the efforts of several very skillful analysts to reduce the smoothness conditions to the conditions (1) - (2) above. It also worth noticing that these conditions are already precise, i.e., if they do not satisfy, the asymptotics (8) might not take place.

\(^3\) In writing the Fisher-Hartwig symbol in form (10) we follow the recent paper \cite{22}. Equation (10) is slightly different from the one accepted in most of the literature devoted to the Fisher-Hartwig generating functions. The “translation” back to the standard form is easy. The main deviation from the standard form is that in (10) the product \(z^{-\beta_j}\) is factored out which allow to better appreciate the non-trivialty of the shifting some of the parameters \(\beta_j\) by integers.

\(^4\) Some important partial results concerning the asymptotics of the Toeplitz determinants with singular symbols were also obtained by A. Lenard \cite{53} and used by Fisher and Hartwig as a strong evidence in favor of their formula.
power-like factors in the asymptotics. Indeed, in the case of all \( \beta_j = 0 \), the Fisher-Hartig formula reads as follows.

\[
D_L[\phi] \sim E_{FH}^0[\phi] L^{\sum_{j=0}^m \alpha_j^2} \exp\left(L V_0\right), \quad L \to \infty.
\]  

(15)

The pre-exponential constant factor, \( E_{FH}^0[\phi] \), is more elaborated than its Szegö counterpart \( E_{Sz}^0[\phi] \) from the Szegö equation (8). The description of \( E_{FH}^0[\phi] \) involves a rather “exotic” special function - the Barnes’ \( G \) - function which is defined by the equations (see e.g. \[75\]),

\[
G(1 + x) = (2\pi)^{x/2} e^{-(x+1)x/2 - \gamma E x^2/2} \prod_{n=1}^{\infty} \left\{ (1 + x/n)^n e^{-x+x^2/(2n)} \right\},
\]

(16)

where \( \gamma_E \) is Euler constant and its numerical value is 0.5772156649 \ldots. The \( G \) - function can be thought of as a “discrete antiderivative” of the \( \Gamma \) - function.

The exact expression for \( E_{FH}^0[\phi] \) is given by the equation (cf. Eq. 9),

\[
E_{FH}^0[\phi] = \exp \left( \sum_{k=1}^{\infty} k V_k V_{-k} \right) \prod_{j=0}^{m} \alpha_j \left( V_0 - V(z_j) \right)
\]

\[
\times \prod_{0 \leq j < k \leq m} |z_j - z_k|^{-2\alpha_j \alpha_k} \prod_{j=0}^{m} \frac{G^2(1 + \alpha_j)}{G(1 + 2\alpha_j)}.
\]

(17)

The double product over \( j < k \) is set to 1 if \( m = 0 \), so that in the absence of singularities, we are back to the strong Szegö limit theorem.

Fisher-Hartwig formula (15) was proven in 1973 by H. Widom [77].

The presence of jumps, under the assumption \( |\Re \beta_j - \Re \beta_k| < 1 \), does not change much the structure of the large \( L \) behavior of the Toeplitz determinant \( D_L[\phi] \). Indeed, it is still the combination of the exponential and the power terms with the exponential term being determined, as before, by only the Szegö part of the symbol while the power factor is determined by both the \( \alpha \) and the \( \beta \) parameters of the Fisher-Hartwig part of the symbol. The Fisher-Hartwig formula for the general case of symbol (10) reads (cf. Eq. 15),

\[
D_L[\phi] \sim E_{FH}[\phi] L^{\sum_{j=0}^m \alpha_j^2 - \beta_j^2} \exp\left(L V_0\right), \quad L \to \infty.
\]

(18)

The pre-exponential constant factor, \( E_{FH}[\phi] \), is now even more complex than in the case of all \( \beta_j = 0 \). In addition to the Barnes’ \( G \) - function, it now involves the canonical Wiener-Hopf factorization of the Szegö part, \( e^{V(z)} \), of the symbol \( \phi(z) \),

\[
e^{V(z)} = b_+(z) e^{V_0} b_-(z), \quad b_+(z) = e^{\sum_{k=1}^{\infty} V_k z^k}, \quad b_-(z) = e^{\sum_{k=-\infty}^{-1} V_k z^k}.
\]

(19)

Note that \( b_+(z) \) and \( b_-(z) \) are analytic inside and outside of the unit circle \( |z| = 1 \), respectively, and they satisfy the normalization conditions \( b_+(0) =
The exact expression for $E_{FH}[\phi]$ is given by the equation (cf. Eq. 9 and Eq. 17),

$$E_{FH}[\phi] = \exp \left( \sum_{k=1}^{\infty} kV_k V_{-k} \right) \prod_{j=0}^{m} b_+(z_j)^{-\alpha_j + \beta_j} b_-(z_j)^{-\alpha_j - \beta_j} \times \prod_{0 \leq j < k \leq m} |z_j - z_k|^{2(\beta_j \beta_k - \alpha_j \alpha_k)} \left( \frac{z_j}{z_j e^{i\pi}} \right)^{\alpha_j \beta_k - \alpha_k \beta_j} \times \prod_{j=0}^{m} \frac{G(1 + \alpha_j + \beta_j)G(1 + \alpha_j - \beta_j)}{G(1 + 2 \alpha_j)} (1 + o(1)).$$ (20)

The proof of the general Fisher-Hartwig formula (18) is due to E. Basor [7] for $\Re \beta_j = 0$, E. Basor [8] for $\alpha_j = 0$, $|\Re \beta_j| < 1/2$, A. Böttcher and B. Silbermann [17] for $|\Re \alpha_j| < 1/2$, $|\Re \beta_j| < 1/2$, T. Ehrhardt [28] for $|\Re \beta_j - \Re \beta_k| < 1$. The precise statement concerning the large $L$ behavior of the Toeplitz determinant $D_L[\phi]$ with the Fisher-Hartwig generating function (10) is given by the following theorem.

**Theorem 2.** (T. Ehrhardt [28]) Let $\phi(z)$ be defined in (10), $V(z)$ be $C^\infty$ on the unit circle, $\Re \alpha_j > -1/2$, $|\Re \beta_j - \Re \beta_k| < 1$, and $\alpha_j \pm \beta_j \neq -1, -2, \ldots$ for $j, k = 0, 1, \ldots, m$. Then, as $L \to \infty$, the asymptotic behavior of the Toeplitz determinant $D_L[\phi]$ is given by the formulae (18) - (20).

A. Böttcher and B. Silbermann [17] in 1985 and E. Basor and C. Tracy [10] in 1991 constructed examples with $\Re \beta_j$ not lying in a single interval of length less than 1 such that the large $L$ asymptotics is very different from the one given by (18). These examples have showed that for the asymptotics (18) to take place, the condition

$$|\Re \beta_j - \Re \beta_k| < 1, \quad \forall j, k = 0, 1, \ldots, m,$$ (21)

is precise. In the case of arbitrary complex $\beta_j$, E. Basor and C. Tracy conjectured in [10] a very elegant structure of the large $L$ asymptotics of the determinant $D_L[\phi]$. They based their arguments on the formal analysis of the behavior of the both sides of estimate (18) with respect to the shifts of the $\beta$ - parameters by integers. A detail description of the Basor-Tracy conjecture can be found in the original paper [10] as well as in the recent work [22] were this conjecture was actually proven with the help of the new technique - the Riemann-Hilbert method.

We refer the reader to monograph [18] and survey [28] for more on the mathematics of Toeplitz determinants with the Fisher-Hartwig symbols.

For the Riemann-Hilbert approach in the theory of Toeplitz determinants, we refer the reader to the papers [22] and [21] where the method was introduced (following the similar approach for the Hankel determinants [32] and the theory of integrable Fredholm determinants [41]) and to the works [49, 50, 58, 57], where the method was further developed. The crucial role in the implementation of the Riemann-Hilbert approach to the Toeplitz determinants is played by the Deift-Zhou nonlinear steepest descent method of the asymptotic analysis of the oscillatory matrix Riemann-Hilbert problems [25] and by its orthogonal polynomial version [24].
2.2 Block Toeplitz determinants

A general asymptotic representation of the determinant of a block Toeplitz matrix, which generalizes the classical strong Szegő theorem to the block matrix case, was obtained by Widom in [78,79] (see also more recent work [16] and references therein).

**Theorem 4.** (H. Widom [79]) Let $\Phi(z)$ be a $N \times N$ matrix function defined on the unit circle and satisfying the conditions,

1. $\det \Phi(\theta) \neq 0$, for all $\theta \in [0, 2\pi]$.
2. $\text{index} \det \Phi(\theta) \equiv \arg \det \Phi(2\pi) - \arg \det \Phi(0) = 0$
3. $\sum_{k=-\infty}^{\infty} |\Phi_k| + \sum_{k=-\infty}^{\infty} |k||\Phi_k|^2 < \infty$,

where $\Phi_k$ are the Fourier coefficients of $\Phi(\theta)$, and $|F|$ denote a matrix norm of the matrix $F$. Then, the asymptotic behavior of the block Toeplitz determinant generated by the symbol $\Phi(z)$ is given by the formulae,

$$D_L[\Phi] \sim E_W[\Phi] \exp \left( \frac{L}{2\pi} \int_0^{2\pi} \ln \det \Phi(\theta) d\theta \right), \quad L \to \infty,$$

$$E_W[\Phi] = \det \left( T_\infty[\Phi] T_\infty[\Phi^{-1}] \right).$$

(22)

(23)

where $T_\infty[\Phi]$ is a semi-infinite Toeplitz matrix,

$$T_\infty[\Phi] = (\Phi_{i-j}), \quad i, j = 1, 2, \cdots.$$  

(24)

From the application point of view, there is an important difference between this result and the Szegő formula (8) for the case of scalar symbols. Indeed, the determinant in the right hand side of Eq. 23 is the Fredholm determinant of an infinite matrix, and already for a $2 \times 2$ matrix symbols the question of effective evaluation of Widom’s pre-factor $E_W[\Phi]$ is a highly nontrivial one, even for a relatively simple matrix functions $\Phi$. Indeed, up until very recently the only general class of matrix functions $\Phi$ for which such effective evaluation is possible has been the class of functions with at least one-side truncated Fourier series. This class was singled out by Widom himself in [78], and this Widom’s result has been used in the recent paper [9] of E. Basor and T. Ehrhardt devoted to the dimer model.

Another class of matrix generating functions which admits an explicit evaluation of Widom’s constant are the algebraic symbols. This fact was demonstrated in the works [39,40,43] for important cases of the block Toeplitz determinants appearing in the analysis of the entanglement entropy in quantum spin chains. For this class of symbols, Widom’s pre-factor admits an explicit evaluation in terms of Jacobi and Riemann theta functions. To give a flavor of these results, we will now present a detail description of the asymptotics of the block Toeplitz determinant related to the XY spin model obtained in [39,40]. We shall also use these formulae later in Section 4.

The Toeplitz determinant in question is generated by the $2 \times 2$ matrix symbol,

$$\Phi(z) = \begin{pmatrix} i\lambda & \phi(z) \\ -\phi^{-1}(z) & i\lambda \end{pmatrix}$$

(25)
where \( z_1 \neq z_2 \) are complex nonzero numbers not lying on the unit circle. Following the needs of the XY model, we shall assume that the both points are from the right half plane though the result we present below can be easily generalized to the arbitrary position of the points \( z_1 \) and \( z_2 \) outside of the unit circle. We will also distinguish three possible locations of the points \( z_1 \) and \( z_2 \) on complex plane.

**Case 1a**: Both \( z_1 \) and \( z_2 \) are real, they lie outside of the unit circle, and we assume that \( z_1 > z_2 > 1 \).

**Case 1b**: Both \( z_1 \) and \( z_2 \) are complex, \( z_1 = z_2^* \), and we assume that \( \Re z_1 > 1 \) and \( \Im z_1 > 0 \).

**Case 2**: Both \( z_1 \) and \( z_2 \) are real, they lie at the different sides of the unit circle, and we assume that \( z_1 > z_2^{-1} > 1 \).

The reason why the Cases 1a and 1b are considered as sub-cases of a single case is that in the both these cases all the root singularities of the function \( \phi(z) \) defined in (26) are inside of the unite circle while all its zeros are outside. In Case 2, the zeros and the singularities are evenly distributed between the inside and the outside of the unit circle. This difference in the position of the roots and singularities of \( \phi(z) \) has an impact to the derivations of the asymptotics and, as we see below, is reflected in the form of the final answer.

We shall also see that in the context of the XY model, Case 1 and Case 2 correspond to the small \( (h < 2) \) and large \( (h > 2) \) magnetic field, respectively.

The complex parameter \( \lambda \) plays role of a spectral parameter for the Toeplitz matrix generated by the symbol,

\[ \phi_0(z) \equiv -\Phi(z)|_{\lambda=0} = \begin{pmatrix} 0 & -\phi(z) \\ \phi^{-1}(z) & 0 \end{pmatrix}. \]  

(27)

Hence the Toeplitz determinant \( D_L[\Phi] \) we are dealing with is in fact a Toeplitz characteristic determinant,

\[ D_L[\Phi] \equiv D_L(\lambda) = \det \left( i\lambda I_L - T_L[\Phi_0] \right). \]  

(28)

Given the branch points \( z_j \) of the symbol \( \Phi(z) \), we introduce now the elliptic curve,

\[ w^2(z) = (z - z_1)(z - z_2)(z - z_2^{-1})(z - z_1^{-1}). \]  

(29)

Let us also re-label the branch points of this curve by the letters \( \lambda_A, \lambda_B, \lambda_C, \) and \( \lambda_D \), according to the following rule. **Case 1a**: \( \lambda_A = z_1^{-1}, \lambda_B = z_2^{-1}, \lambda_C = z_2, \lambda_D = z_1; \)** **Case 1b**: \( \lambda_A = z_1^{-1}, \lambda_B = z_2^{-1}, \lambda_C = z_1, \lambda_D = z_2, \)** **Case 2**: \( \lambda_A = z_1^{-1}, \lambda_B = z_2, \lambda_C = z_2^{-1}, \lambda_D = z_1. \) Observe that \( \lambda_A \) and \( \lambda_B \) are always inside the unite circle while \( \lambda_C \) and \( \lambda_D \) are always outside. This new relabeling of the branch points allows to introduce the module parameter of elliptic curve (29) in the universal way,

\[ \tau = \frac{2}{c} \int_{\lambda_B}^{\lambda_C} \frac{dz}{w(z)}, \quad c = 2 \int_{\lambda_A}^{\lambda_B} \frac{dz}{w(z)}. \]  

(30)
Theorem 5. ([39,40]) Let
\[ \theta_3(s) = \sum_{n=-\infty}^{\infty} e^{\pi i \tau n^2 + 2\pi i sn}, \] (31)
where \( \tau \) is taken from (30), be the third Jacobi theta-function associated with the curve (29). Then, the large \( L \) asymptotic behavior of the determinant \( D_L(\lambda) \) is given by the equations,
\[ D_L(\lambda) \sim \frac{\theta_3 (\beta(\lambda) + \frac{\sigma \tau}{2}) \theta_3 (\beta(\lambda) - \frac{\sigma \tau}{2})}{\theta_3^2 \left( \frac{\sigma \tau}{2} \right)} (1 - \lambda^2)^L, \quad L \to \infty \] (32)
where
\[ \beta(\lambda) = \frac{1}{2\pi i} \ln \frac{\lambda + 1}{\lambda - 1}, \] (33)
and \( \sigma = 1 \) in Case 1 and \( \sigma = 0 \) in Case 2.

Remark. The theta-functions involved in the asymptotic formula Eq. (32) has zeros at the points
\[ \pm \lambda_m, \quad \lambda_m = \tanh \left( m + \frac{1 - \sigma}{2} \right) \pi \tau_0, \quad m \geq 0, \] (34)
where,
\[ \tau_0 = -i \tau = -i \frac{\lambda C}{\lambda A} \frac{dz}{w(z)} > 0. \]
The asymptotics (32) is uniform outside of the arbitrary fixed neighborhoods of the points \( \lambda = \pm 1 \) and \( \lambda = \pm \lambda_m \).

Observe that in the case under consideration, \( \det \Phi(z) \equiv 1 - \lambda^2 \). Therefore, the last factor in (32) is exactly the exponential term of the general Widom-Szego formula (22) written for symbol (25). The rest of (32) gives then the corresponding Widom’s constant, i.e.
\[ E_W[\Phi] = \frac{\theta_3 (\beta(\lambda) + \frac{\sigma \tau}{2}) \theta_3 (\beta(\lambda) - \frac{\sigma \tau}{2})}{\theta_3^2 \left( \frac{\sigma \tau}{2} \right)}. \] (35)

Similar formulæ for the case of the more general quantum spin chains were obtained in [43]. The relevant generating function has the same matrix structure (25) with the scalar function \( \phi(z) \) defined by the equation,
\[ \phi(z) := \sqrt{\frac{p(z)}{z^{2n} p(1/z)}} \] (36)
and \( p(z) \) is a polynomial of degree \( 2n \). The analog of the formulæ (32) - (35) in the case \( n > 1 \) involves, instead of elliptic, the hyperelliptic integrals and, instead of the Jacobi theta-function, the \( 2n - 1 \) dimensional Riemann theta-function.

The methods that lead to these results, involves the theory of integrable Fredholm operators [41,38,21] and the use of the algebraic geometric techniques of the soliton theory (see e.g. [12]).
3 XY Model and Block Entropy

The Hamiltonian of XY model can be written as

\[ H = - \sum_{n=-\infty}^{\infty} (1 + \gamma) \sigma_n^x \sigma_{n+1}^x + (1 - \gamma) \sigma_n^y \sigma_{n+1}^y + h \sigma_n^z \]  

(37)

Here \( \sigma_n^x, \sigma_n^y, \sigma_n^z \) are Pauli matrices and \( h \) is a magnetic field; Without loss generality, the anisotropy parameter \( \gamma \) can be taken as \( 0 \leq \gamma \); Case with \( \gamma = 0 \) is usually called XX model. The model was solved in [54,1,5,6] and it owns a unique ground state \( |GS\rangle \). Toeplitz determinants were used for evaluation of some correlation functions[6,69]; Integrable Fredholm operators were used for calculation of other correlations[42,26,46]. When the system is in the ground state, the entropy for this whole system is zero but the entropy of a sub-system can be positive. We calculate the entropy of a sub-system (a block of L neighboring spins) which can measure the entanglement between this sub-system and the rest part[45]. We treat the whole chain as a binary system \( |GS\rangle = |A&B\rangle \), where we denote the block of L neighboring spins by sub-system A and the rest part by sub-system B. The density matrix of the ground state can be denoted by \( \rho_{AB} = |GS\rangle \langle GS| \). The density matrix of sub-system A is \( \rho_A = Tr_B(\rho_{AB}) \). Von Neumann entropy \( S(\rho_A) \) of the sub-system A can be represented as following:

\[ S(\rho_A) = -Tr_A(\rho_A \ln \rho_A). \]  

(38)

This entropy also defines the dimension of the Hilbert space of states of the block of L spins.

3.1 Derivation

Following Ref. [54], [55], we introduce two Majorana operators

\[ c_{2l-1} = (\prod_{n=1}^{l-1} \sigma_n^z) \sigma_l^x \]  and \[ c_{2l} = (\prod_{n=1}^{l-1} \sigma_n^z) \sigma_l^y, \]  

(39)

on each site of the spin chain. Operators \( c_n \) are hermitian and obey the anti-commutation relations \( \{c_m, c_n\} = 2\delta_{mn} \). In terms of operators \( c_n \), Hamiltonian \( H_{XX} \) can be rewritten as

\[ H_{XX}(h) = i \sum_{n=1}^{N} (c_{2n}c_{2n+1} - c_{2n-1}c_{2n+2} + hc_{2n-1}c_{2n}). \]  

(40)

Here different boundary effects can be ignored because we are only interested in cases with \( N \to \infty \). This Hamiltonian can be subsequently diagonalized by linearly transforming the operators \( c_n \). It has been obtained [54,5] (also see [73,52]) that

\[ \langle GS|c_n|GS\rangle = 0, \quad \langle GS|c_m c_n|GS\rangle = \delta_{mn} + i(B_N)_{mn}. \]  

(41)
Here matrix $B_N$ can be written in a block form as

$$B_N = \begin{pmatrix} 
\Pi_0 & \Pi_{-1} \cdots & \Pi_{1-N} \\
\Pi_{1} & \Pi_0 & \vdots \\
\vdots & \vdots & \ddots \\
\Pi_{N-1} & \cdots & \Pi_0 
\end{pmatrix}$$

and \( \Pi_I = \frac{1}{2\pi} \int_0^{2\pi} d\theta e^{-i\theta} \Phi_0(\theta) \), \( (42) \)

where both $\Pi_I$ and $\Phi_0(\theta)$ (for $N \to \infty$) are $2 \times 2$ matrix,

$$\Phi_0(\theta) = \begin{pmatrix} 0 & \phi(\theta) \\
-\phi^{-1}(\theta) & 0 \end{pmatrix} \quad \text{and} \quad \phi(\theta) = \frac{\cos \theta - i\gamma \sin \theta - h/2}{\cos \theta - i\gamma \sin \theta - h/2}, \quad (43)$$

Other correlations such as $\langle GS|c_m \cdots c_n|GS \rangle$ are obtainable by Wick theorem. The Hilbert space of sub-system $A$ can be spanned by $\prod_{l=1}^L \{ \sigma^\pm_l \} p_i (|0\rangle_F)$, where $\sigma^\pm_l$ is Pauli matrix, $p_i$ takes value 0 or 1, and vector $|0\rangle_F$ denotes the ferromagnetic state with all spins up. It’s possible to construct a set of fermionic operators $b_l$ and $b^+_l$ by defining

$$d_m = \sum_{n=1}^{2L} v_{mn} c_n, \quad m = 1, \cdots, 2L; \quad b_l = (d_{2l} + id_{2l+1})/2, \quad l = 1, \cdots, L \quad (44)$$

with $v_{mn} = (V)_{mn}$. Here matrix $V$ is an orthogonal matrix. It’s easy to verify that $d_m$ is hermitian operator and

$$b^+_l = (d_{2l} - id_{2l+1})/2, \quad \{ b_i, b_j \} = 0, \quad \{ b^+_i, b^+_j \} = 0, \quad \{ b^+_i, b_j \} = \delta_{i,j}. \quad (45)$$

In terms of fermionic operators $b_l$ and $b^+_l$, the Hilbert space can also be spanned by $\prod_{l=1}^L \{ b^+_l \} p_i |0\rangle_{vac}$. Here $p_i$ takes value 0 or 1, 2L fermionic operators $b_l, b^+_l$ and vacuum state $|0\rangle_{vac}$ can be constructed by requiring

$$b_l |0\rangle_{vac} = 0, \quad l = 1, \cdots, L. \quad (46)$$

We shall choose a specific orthogonal matrix $V$ later.

Let $\{ \psi_I \}$ be a set of orthogonal basis for Hilbert space of any physical system. Then the most general form for density matrix of this physical system can be written as

$$\rho = \sum_{I,J} c(I, J)|\psi_I\rangle\langle\psi_J|. \quad (47)$$

Here $c(I, J)$ are complex coefficients. We can introduce a set of operators $P(I, J)$ by $P(I, J) \propto |\psi_I\rangle\langle\psi_J|$ and $\tilde{P}(I, J)$ satisfying

$$\tilde{P}(I, J)P(J, K) = \delta_{I,K}|\psi_I\rangle\langle\psi_J|, \quad P(I, J)\tilde{P}(J, K) = \delta_{I,K}|\psi_I\rangle\langle\psi_J|. \quad (48)$$

There is no summation over repeated index in these formula. We shall use an explicit summation symbol through the whole paper. Then we can write the density matrix as

$$\rho = \sum_{I,J} \hat{c}(I, J)P(I, J), \quad \hat{c}(I, J) = Tr(\rho \tilde{P}(J, I)). \quad (49)$$
Now let us consider quantum spin chain defined in Eq. 37. For the sub-system A, the complete set of operators $P(I, J)$ can be generated by $\prod_{i=1}^{L} O_i$. Here we take operator $O_i$ to be any one of the four operators $\{b_i^+, b_i, b_i^* b_i, b_i b_i^+\}$ (Remember that $b_i$ and $b_i^+$ are fermionic operators defined in Eq. 44). It’s easy to find that $P(J, I) = (\prod_{i=1}^{L} O_i)^\dagger$ if $P(I, J) = \prod_{i=1}^{L} O_i$. Here $\dagger$ means hermitian conjugation. Therefore, the reduced density matrix for sub-system A can be represented as

$$\rho_A = \sum Tr_{AB} \left( \rho_{AB} (\prod_{i=1}^{L} O_i)^\dagger \right) \prod_{i=1}^{L} O_i. \quad (50)$$

Here the summation is over all possible different terms $\prod_{i=1}^{L} O_i$. For the whole system to be in pure state $\langle GS \rangle$, the density matrix $\rho_{AB}$ is represented by $\langle GS \rangle \langle GS \rangle$. Then we have the expression for $\rho_A$ as following

$$\rho_A = \sum \langle GS \rangle (\prod_{i=1}^{L} O_i)^\dagger \langle GS \rangle \prod_{i=1}^{L} O_i \ . \quad (51)$$

This is the expression of density matrix with the coefficient related to multi-point correlation functions. These correlation functions are well studied in the physics literature [15]. Now let us choose matrix $V$ in Eq. 44 so that the set of fermionic basis $\{b_i^+\}$ and $\{b_i\}$ satisfy an equation

$$\langle GS | b_i b_j | GS \rangle = 0, \quad \langle GS | b_i^+ b_j | GS \rangle = \delta_{i,j} \langle GS | b_i^+ b_i | GS \rangle. \quad (52)$$

Then the reduced density matrix $\rho_A$ represented as sum of products in Eq. 51 can be represented as a product of sums

$$\rho_A = \prod_{i=1}^{L} \left( \langle GS | b_i^+ b_i | GS \rangle b_i^+ b_i + \langle GS | b_i b_i^+ | GS \rangle b_i b_i^+ \right). \quad (53)$$

Here we used the equations $\langle GS | b_i | GS \rangle = 0 = \langle GS | b_i^+ | GS \rangle$ and Wick theorem. This fermionic basis was suggested in Ref. [73,52].

Now let us find a matrix $V$ in Eq. 44, which will block-diagonalize correlation functions of Majorana operators $c_n$. From Eqs. 44 and 42, we have the following expression for correlation function of $d_n$ operators:

$$\langle GS | d_m d_n | GS \rangle = \sum_{i=1}^{2L} \sum_{j=1}^{2L} \nu_{mi} \langle GS | c_i c_j | GS \rangle \nu_{jn} ,$$

$$\langle GS | c_m c_n | GS \rangle = \delta_{mn} + i(B_L)_{mn},$$

$$\langle GS | d_m d_n | GS \rangle \delta_{mn} + i(\tilde{B}_L)_{mn}. \quad (54)$$

The last equation is the definition of a matrix $\tilde{B}_L$. Matrix $B_L$ is the sub-matrix of $B_N$ defined in Eq. 42 with $m, n = 1, 2, \ldots, L$. We also require $\tilde{B}_L$ to be the form [73,52]

$$\tilde{B}_L = V B_L V^T = \otimes_{m=1}^{L} \nu_m \left( \begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array} \right) = \Omega \otimes \left( \begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array} \right). \quad (55)$$
Here matrix $\Omega$ is a diagonal matrix with elements $\nu_m$ (all $\nu_m$ are real numbers). Therefore, choosing matrix $V$ satisfying Eq. 55 in Eq. 44, we obtain $2L$ operators $\{b_l\}$ and $\{b_l^+\}$ with following expectation values
\[
\langle GS | b_m | GS \rangle = 0, \quad \langle GS | b_m b_n | GS \rangle = 0, \quad \langle GS | b_m^+ b_n | GS \rangle = \delta_{mn} \frac{1 + \nu_m}{2}.
\] (56)

Using the simple expression for reduced density matrix $\rho_A$ in Eq. 53, we obtain
\[
\rho_A = \prod_{i=1}^L \left( \frac{1 + \nu_i}{2} b_i^+ b_i + \frac{1 - \nu_i}{2} b_i b_i^+ \right).\] (57)

This form immediately gives us all the eigenvalues $\lambda_{x_1, x_2, \ldots, x_L}$ of reduced density matrix $\rho_A$,
\[
\lambda_{x_1, x_2, \ldots, x_L} = \prod_{i=1}^L \frac{1 + (-1)^{x_i} \nu_i}{2}, \quad x_i = 0, 1 \quad \forall i.
\] (58)

Note that in total we have $2^{2L}$ eigenvalues. Hence, the entropy of $\rho_A$ from Eq. 38 becomes
\[
S(\rho_A) = \sum_{m=1}^L e(1, \nu_m)
\] (59)
with
\[
e(x, \nu) = -\frac{x + \nu}{2} \ln \left( \frac{x + \nu}{2} \right) - \frac{x - \nu}{2} \ln \left( \frac{x - \nu}{2} \right).
\] (60)

### 3.2 XX model

Notice further that for XX model, i.e. $\gamma = 0$ case, matrix $B_L$ can have a direct product form
\[
B_L = G_L \otimes \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}
\] with
\[
G_L = \begin{pmatrix} \phi_0 & \phi_{-1} & \ldots & \phi_{1-L} \\
\phi_1 & \phi_0 & \ldots & \vdots \\
\vdots & \ddots & \ddots & \vdots \\
\phi_{1-L} & \ldots & \ldots & \phi_0 \end{pmatrix},
\] (61)

where $\phi_l$ is defined as
\[
\phi_l = \frac{1}{2 \pi} \int_0^{2\pi} d\theta e^{-il\theta} \phi(\theta), \quad \phi(\theta) = \begin{cases} 1, & -k_F < \theta < k_F, \\
-1, & k_F < \theta < (2\pi - k_F) \end{cases}
\] (62)

and $k_F = \arccos(|h|/2)$. From Eqs. 55 and 61, we conclude that all $\nu_m$ are just the eigenvalues of real symmetric matrix $G_L$.

However, to obtain all eigenvalues $\nu_m$ directly from matrix $G_L$ is a non-trivial task. Let us introduce
\[
D_L(\lambda) = \det(\tilde{G}_L(\lambda) \equiv \lambda I_L - G_L).
\] (63)
Here $\tilde{G}_L$ is a Toeplitz matrix and $I_L$ is the identity matrix of dimension $L$. Obviously we also have

$$D_L(\lambda) = \prod_{m=1}^{L} (\lambda - \nu_m). \quad (64)$$

From the Cauchy residue theorem and analytical property of $e(x, \nu)$, then $S(\rho_A)$ can be rewritten as

$$S(\rho_A) = \lim_{\epsilon \to 0^+} \frac{1}{2\pi i} \oint_{\Gamma} d\lambda e(1 + \epsilon, \lambda) \frac{d}{d\lambda} \ln D_L(\lambda). \quad (65)$$

Here the contour $\Gamma'$ in Fig 1 encircles all zeros of $D_L(\lambda)$ and function $e(1 + \epsilon, \lambda)$ is analytic within the contour. Just like Toeplitz matrix $G_L$ is

![Fig. 1 Contours $\Gamma'$ (smaller one) and $\Gamma$ (larger one). Bold lines $(-\infty, -1 - \epsilon)$ and $(1 + \epsilon, \infty)$ are the cuts of integrand $e(1 + \epsilon, \lambda)$. Zeros of $D_L(\lambda)$ (Eq. 64) are located on bold line $(-1, 1)$. The arrow is the direction of the route of integral we take and $r$ and $R$ are the radius of circles.](image)

generated by function $\phi(\theta)$ in Eqs. 61 and 62, Toeplitz matrix $\tilde{G}_L(\lambda)$ is generated by function $\tilde{\phi}(\theta)$ defined by

$$\tilde{\phi}(\theta) = \begin{cases} 
\lambda - 1, & -k_F < \theta < k_F, \\
\lambda + 1, & k_F < \theta < (2\pi - k_F).
\end{cases} \quad (66)$$

Notice that $\tilde{\phi}(\theta)$ is a piecewise constant function of $\theta$ on the unit circle, with jumps at $\theta = \pm k_F$. Hence, if one can obtain the determinant of this Toeplitz matrix analytically, one will be able to get a closed analytical result.
for $S(\rho_A)$ which is our new result. Now, the calculation of $S(\rho_A)$ reduces to the calculation of the determinant of Toeplitz matrix $\tilde{G}_L(\lambda)$.

3.3 XY model

Similarly let us introduce:

$$\tilde{B}_L(\lambda) = i\lambda I_L - B_L, \quad D_L(\lambda) = \det \tilde{B}_L(\lambda).$$

Here $I_L$ is the identity matrix of dimension $2L$. By definition, we have

$$D_L(\lambda) = (-1)^L \prod_{m=1}^{L} (\lambda^2 - \nu_m^2).$$

Using again the Cauchy residue theorem we obtain that, similar to (65),

$$S(\rho_A) = \lim_{\epsilon \to 0} \frac{1}{4\pi i} \oint_{\Gamma'} d\lambda \epsilon(1 + \epsilon, \lambda) \frac{d}{d\lambda} \ln D_L(\lambda).$$

Here the contour $\Gamma'$ in Fig 1 encircles all zeros of $D_L(\lambda)$.

We also realized that $\tilde{B}_L(\lambda)$ is a block Toeplitz matrix with the generator $\Phi(z)$, i.e.

$$\tilde{B}_L(\lambda) = \begin{pmatrix} \tilde{\Pi}_0 & \tilde{\Pi}_{-1} \cdots \tilde{\Pi}_{1-L} \\ \tilde{\Pi}_1 & \tilde{\Pi}_0 & \cdots \\ \vdots & \ddots & \ddots \\ \tilde{\Pi}_{L-1} \cdots \tilde{\Pi}_0 \end{pmatrix}$$

with

$$\tilde{\Pi}_l = \frac{1}{2\pi i} \oint_{\Xi} dz z^{-l-1} \Phi(z), \quad \Phi(z) = \begin{pmatrix} i\lambda & \phi(z) \\ -\phi^{-1}(z) & i\lambda \end{pmatrix}$$

and

$$\phi(z) = \frac{(1 - \lambda_1 z)(1 - \lambda_2 z^{-1})}{(1 - \lambda_1^* z)(1 - \lambda_2^* z^{-1})}^{1/2}$$

We fix the branch by requiring that $\phi(\infty) > 0$. We use * to denote complex conjugation and $\Xi$ the unit circle shown in Fig. 2. $\lambda_1$ and $\lambda_2$ are defined differently for different values of $\gamma$ and $h$. There are following three different cases:

In Case 1a ($2\sqrt{1-\gamma^2} < h < 2$) and Case 2 ($h > 2$), both $\lambda_1$ and $\lambda_2$ are real

$$\lambda_1 = \frac{h - \sqrt{h^2 - 4(1-\gamma^2)}}{2(1+\gamma)}, \quad \lambda_2 = \frac{1+\gamma}{1-\gamma} \lambda_1.$$  

In Case 1b ($h^2 < 4(1-\gamma^2)$), both $\lambda_1$ and $\lambda_2$ are complex

$$\lambda_1 = \frac{h - i\sqrt{4(1-\gamma^2) - h^2}}{2(1+\gamma)}, \quad \lambda_2 = 1/\lambda_1^*.$$  

Note that in the Case 1 the poles of function $\phi(z)$ (Eq. 72) coincide with the points $\lambda_A$ and $\lambda_B$, while in the Case 2 they coincide with the points $\lambda_A$ and $\lambda_C$. 
**Fig. 2** Polygonal line $\Sigma$ (direction as labeled) separates the complex $z$ plane into the two parts: the part $\Omega_+$ which lies to the left of $\Sigma$, and the part $\Omega_-$ which lies to the right of $\Sigma$. Curve $\Xi$ is the unit circle in anti-clockwise direction. Cuts $J_1, J_2$ for functions $\phi(z), w(z)$ are labeled by bold on line $\Sigma$. Definition of the end points of the cuts $\lambda_1, \lambda_2$ depends on the case:

**Case 1a**:
- $\lambda_A = \lambda_1$ and $\lambda_B = \lambda_2 - 1$, $\lambda_C = \lambda_2$ and $\lambda_D = \lambda_1$.
- Case 1b: $\lambda_A = \lambda_1$ and $\lambda_B = \lambda_2 - 1$, $\lambda_C = \lambda_1 - 1$ and $\lambda_D = \lambda_2$.

**Case 2**:
- $\lambda_A = \lambda_1$ and $\lambda_B = \lambda_2$, $\lambda_C = \lambda_2 - 1$ and $\lambda_D = \lambda_1$.

---

**4 Block entropy of XX model and Fisher-Hartwig Formula**

From Eq. 65, one needs the calculation of Toeplitz determinant $D_L(\lambda)$ with a singular generating function

$$\tilde{\phi}(\theta) = \begin{cases} 
  \lambda - 1, & -k_F < \theta < k_F, \\
  \lambda + 1, & k_F < \theta < (2\pi - k_F).
\end{cases} \tag{75}$$

It is easy to check that this function admits the canonical Fisher-Hartwig factorization given by Eq. 10 with

$$m = 2, \quad \alpha_j = 0 \quad \forall j, \quad \beta_0 = 0, \quad \beta_2 = -\beta_1 \equiv \beta(\lambda) = \frac{1}{2\pi i} \ln \frac{\lambda + 1}{\lambda - 1}, \quad \tag{76}$$

and

$$e^{V(z)} \equiv e^{V_0} = \left(\lambda + 1 \frac{\lambda + 1}{\lambda - 1}\right)^{-k_F/\pi} \tag{77}.$$ 

The branch of the logarithm is fixed by the condition,

$$-\pi \leq \arg \left(\frac{\lambda + 1}{\lambda - 1}\right) < \pi, \quad \tag{78}$$

For $\lambda \notin [-1, 1]$, the left inequality is also strict, and hence $|\Re(\beta_1(\lambda))| < \frac{1}{2}$ and $|\Re(\beta_2(\lambda))| < \frac{1}{2}$. Therefore, Theorem 2 is applicable (indeed, even its earlier
weaker version proven by E. Basor [8] would be suffice) and we see that the determinant \( D_L(\lambda) \) of \( \lambda I_L - G_L \) can be asymptotically represented as

\[
D_L(\lambda) = \left(2 - 2 \cos(2k_F)\right)^{-\beta^2(\lambda)} \left\{ G(1 + \beta(\lambda)) G(1 - \beta(\lambda)) \right\}^2 \\
\left\{ (\lambda + 1) \left( (\lambda + 1)/(\lambda - 1) \right)^{-k_F/\pi} \right\}^L L^{-2\beta^2(\lambda)}.
\]  

(79)

Here \( G \) is, as before, the Barnes \( G \)-function and

\[
G(1 + \beta(\lambda)) G(1 - \beta(\lambda)) = e^{-(1+\gamma_E)\beta^2(\lambda)} \prod_{n=1}^{\infty} \left\{ 1 - \frac{\beta^2(\lambda)}{n^2} \right\}^n e^{\beta^2(\lambda)/n^2}.
\]  

(80)

Let us substitute the asymptotic form Eq. 79 into Eq. 65 and after some simplification[45], we have that

\[
S(\rho_A) = \frac{1}{3} \ln L + \frac{1}{6} \ln \left( 1 - \left( \frac{h}{2} \right)^2 \right) + \frac{\ln 2}{3} + \Upsilon_1, \quad L \to \infty
\]  

(81)

with

\[
\Upsilon_1 = -\int_0^\infty dt \left\{ \frac{e^{-t}}{3t} + \frac{1}{t \sinh^2(t/2)} - \frac{\cosh(t/2)}{2 \sinh^2(t/2)} \right\}.
\]  

(82)

for XX model. The leading term of asymptotic of the entropy \( \frac{1}{4} \ln L \) in Eq. 81 was first obtained based on numerical calculation and a simple conformal argument in Ref. [73,52] in the context of entanglement. We also want to mention that a complete conformal derivation for this entropy was found in Ref. [48]. One can numerically evaluate \( \Upsilon_1 \) to very high accuracy to be 0.4950179 \ldots. For zero magnetic field (\( h = 0 \)) case, the constant term \( \Upsilon_1 + \ln 2/3 \) for \( S(\rho_A) \) is close to but different from \( (\pi/3) \ln 2 \), which can be found by taking numerical accuracy to be more than five digits.

5 Block entropy of XY model and block Toeplitz determinant

For the block entropy of XY model, by virtue of Eq. 69, our objective becomes the asymptotic calculation of the determinant of block Toeplitz matrix \( D_L(\lambda) \) or, rather, its \( \lambda \)-derivative \( \frac{d}{d\lambda} \ln D_L(\lambda) \).

Let us denote,

\[
z_1 := \lambda_1^{-1}, \quad \text{and} \quad z_2 := \lambda_2.
\]  

(83)

It is easy to check than that the generating function introduced in Eq. 71) - Eq. 72 coincides with the one introduced in Eq. 25) - Eq. 26 together with the case-separations and the \( \lambda_A - \lambda_D \) labeling of the branch points. Hence one can use Theorem 5 and substitute the asymptotic form Eq. 32 into Eq. 69.
Deforming the original contour of integration to the contour $\Gamma$ as indicated in Fig. 1 we arrive at the following expression for the entropy $[39,40]$:

$$S(\rho_A) = \frac{1}{2} \int_1^{\infty} \ln \left( \frac{\theta_3 (\beta (\lambda) + \frac{\sigma \tau^2}{\gamma}) \theta_3 (\beta (\lambda) - \frac{\sigma \tau^2}{\gamma})}{\theta_3^2 (\frac{\sigma \tau^2}{\gamma})} \right) d\lambda, \quad (84)$$

which can also be written in the form,

$$S(\rho_A) = \frac{\pi}{2} \int_0^{\infty} \ln \left( \frac{\theta_3 (ix + \frac{\sigma \tau^2}{\gamma}) \theta_3 (ix - \frac{\sigma \tau^2}{\gamma})}{\theta_3^2 (\frac{\sigma \tau^2}{\gamma})} \right) \frac{dx}{\sinh^2 (\pi x)} \quad (85)$$

This is a limiting expression as $L \to \infty$. In $[40]$ it is also proven that the corrections in Eq. 84 are of order of $O (\lambda - L C / \sqrt{L})$.

The entropy has singularities at phase transitions. When $\tau \to 0$ we can use Landen transform (see [75]) to get the following estimate of the theta-function for small $\tau$ and pure imaginary $s$:

$$\ln \frac{\theta_3 (s \pm \frac{\sigma \tau^2}{\gamma})}{\theta_3 (\frac{\sigma \tau^2}{\gamma})} = \frac{\pi i \tau s^2}{4 \tau^2} \pm \pi i \sigma s + O \left( \frac{e^{-i\pi/\tau}}{\tau^2 s^2} \right), \quad \text{as } \tau \to 0.$$  

Now the leading term in the expression for the entropy (84) can be replaced by

$$S(\rho_A) = \frac{i\pi}{6\tau} + O \left( \frac{e^{-i\pi/\tau}}{\tau^2} \right) \quad \text{for } \tau \to 0. \quad (86)$$

Let us consider two physical situations corresponding to small $\tau$ depending on the case defined on the page 2:

1. **Critical magnetic field**: $\gamma \neq 0$ and $h \to 2$.
   This is included in our Case 1a and Case 2, when $h > 2 \sqrt{1 - \gamma^2}$. As $h \to 2$ the end points of the cuts $\lambda_B \to \lambda_C$, so $\tau$ given by Eq. (30) simplifies and we obtain from Eq. (86) that the entropy is:

   $$S(\rho_A) = -\frac{1}{6} \ln |2 - h| + \frac{1}{3} \ln 4 \gamma, \quad \text{for } h \to 2 \text{ and } \gamma \neq 0 \quad (87)$$

   correction is $O(|2 - h|/\ln^2 |2 - h|)$. This limit agrees with predictions of conformal approach $[48,19]$. The first term in the right hand side of (87) can be represented as $(1/6) \ln \xi$, this confirms a conjecture of [19]. The correlation length $\xi$ was evaluated in [5].

2. **An approach to $XX$ model**: $\gamma \to 0$ and $h < 2$: It is included in Case 1b, when $0 < h < 2 \sqrt{1 - \gamma^2}$. Now $\lambda_B \to \lambda_C$ and $\lambda_A \to \lambda_D$, we can calculate $\tau$ explicitly. The entropy becomes:

   $$S^0(\rho_A) = -\frac{1}{3} \ln \gamma + \frac{1}{6} \ln (4 - h^2) + \frac{1}{3} \ln 2, \quad \text{for } \gamma \to 0 \text{ and } h < 2 \quad (88)$$

   correction is $O(\gamma \ln^2 \gamma)$. This agrees with $[45]$ (see also Eq. 81).
As it has already been indicated, the theta-functions involved in the asymptotic formula Eq. (32) has zeros at the points $\pm \lambda_m$ which are defined in Eq. (34). Theorem 5 shows, in particular, that in the large $L$ limit, the points $\pm \lambda_m$ are double zeros of the $D_L(\lambda)$. More precisely, we see that in the large $L$ limit the eigenvalues $\nu_{2m}$ and $\nu_{2m+1}$ from (59) merge to $\lambda_m$:

$$\nu_{2m}, \nu_{2m+1} \to \lambda_m,$$

which in turn implies (cf. Eq. 59) the following equivalent description of the limiting entropy $S(\rho_A)$ [39]:

The limiting entropy, $S(\rho_A)$, of the subsystem can be identified with the infinite convergent series,

$$S(\rho_A) = \sum_{m=-\infty}^{\infty} e(1, \lambda_m) = \sum_{m=-\infty}^{\infty} (1 + \lambda_m) \ln \frac{2}{1 + \lambda_m} \div \tag{90}$$

Indeed, equation (90) follows from the substitution of Eq. (32) into Eq. (69) and integrating over the original contour $\Gamma'$ of Fig. 1.

It is also worth mentioning that relation (89) also indicates the degeneracy of the spectrum of the matrix $B_L$ and an appearance of an extra symmetry in the large $L$ limit.

**Remark.** These numbers $\lambda_m$ satisfy an estimate:

$$|\lambda_{m+1} - \lambda_m| \leq 4\pi \tau_0 \quad \text{with} \quad \tau_0 = -i\tau.$$

This means that $(\lambda_{m+1} - \lambda_m) \to 0$ as $\tau \to 0$ for every $m$. This is useful for understanding of large $L$ limit of the $XX$ case corresponding to $\gamma \to 0$, as considered in [45]. The estimate explains why in the $XX$ case the singularities of the logarithmic derivative of the Toeplitz determinant $d \ln D_L(\lambda)/d\lambda$ form a cut along the interval $[-1, 1]$, while in the $XY$ case it has a discrete set of poles at points $\pm \lambda_m$ of Eq. (34).

The higher genus analog of formula Eq. (84) for the class of quantum spin chains introduced by J. Keating and F. Mezzadri in [47] has been obtained in [43].

**Remark.** It was shown by Peschel in [65] (who also suggested an alternative heuristic derivation of equation (90) based on the work [19]), the series (90) can be summed up to an elementary function of the complete elliptic integrals corresponding to the modular parameter $\tau$ - see Eqs 109 and 110 below. It is an open problem whether an analogous representation of the integral Eq. (84) exists for higher genus. The key issue here is the extreme complexity of the identification of the zero divisor of the theta- functions in the dimension greater than 1.

### 6 Renyi entropy and the spectrum of reduced density matrix of XY model

The Renyi entropy of $S_\alpha(\rho_A)$ of the block of spins is defined by the expression

$$S_\alpha(\rho_A) = \frac{1}{1-\alpha} \ln Tr(\rho_A^\alpha), \quad \alpha \neq 1 \quad \text{and} \quad \alpha > 0. \quad \tag{91}$$
Here the power $\alpha$ is a parameter. The Renyi entropy is intimately related to the spectrum of the reduced density matrix $\rho_A$. Indeed, let $\lambda_n$, $(0 < \lambda_n < 1)$ and $a_n$ denote the eigenvalues and their multiplicities of the operator $\rho_A$. The spectrum is completely determined by its momentum function, i.e. by the $\zeta$-function of $\rho_A$:

$$
\zeta_{\rho_A}(\alpha) = \sum_{n=0}^{\infty} a_n \lambda_n^\alpha.
$$

(92)

The obvious equation takes place,

$$
\zeta_{\rho_A}(\alpha) = e^{(1-\alpha)S_R(\rho_A,\alpha)}.
$$

(93)

The key point is that we can evaluate $S_R(\rho_A,\alpha)$, and hence $\zeta_{\rho_A}(\alpha)$, explicitly.

As it is shown in [45], the Renyi entropy $S_R(\rho_A)$ of a block of $L$ neighboring spins, before the large $L$ limit is taken, can be represented by the finite sum,

$$
S_R(\rho_A,\alpha) = \frac{1}{1-\alpha} \sum_{k=1}^{L} \ln \left[ \left( \frac{1+\nu_k}{2} \right)^\alpha + \left( \frac{1-\nu_k}{2} \right)^\alpha \right],
$$

(94)

where the numbers

$$
\pm i\nu_k, \quad k = 1, ..., L
$$

are the eigenvalues of the same block Toeplitz matrix Eq. 68 as we worked with in Section 3.4. In virtue of Eq. (89), the Renyi entropy in the large $L$ limit can be identified with the convergent series,

$$
S_R(\rho_A,\alpha) = \frac{1}{1-\alpha} \sum_{m=-\infty}^{\infty} \ln \left[ \left( \frac{1+\lambda_m}{2} \right)^\alpha + \left( \frac{1-\lambda_m}{2} \right)^\alpha \right],
$$

(95)

with

$$
\lambda_m = \tanh \left( m + \frac{1-\sigma}{2} \right) \pi \tau_0.
$$

(96)

The summation of the series can be done following the same approach as in [65] in the case of the von Neuman entropy. The result is (for details see [33]) the following,

$$
S_R(\rho_A,\alpha) = \frac{\alpha}{1-\alpha} \left( \frac{\pi \tau_0}{12} + \frac{1}{6} \ln \frac{k}{4} + \frac{1}{1-\alpha} \ln \prod_{n=0}^{\infty} (1 + q^{2n+1}_\alpha)^2 \right),
$$

(97)

$$
q_\alpha = e^{-\alpha \pi \tau_0},
$$

(98)

for the case $h > 2$, and

$$
S_R(\rho_A,\alpha) = \frac{\alpha}{1-\alpha} \left( -\frac{\pi \tau_0}{6} + \frac{1}{6} \ln \frac{k'}{4k^2} + \frac{1}{1-\alpha} \ln \prod_{n=1}^{\infty} (1 + q^{2n}_\alpha)^2 \right) + \frac{1}{1-\alpha} \ln 2,
$$

(99)

$$
q_\alpha = e^{-\alpha \pi \tau_0},
$$

(98)
for the case $h < 2$. In these equations, $\tau_0 \equiv -i\tau$ is the module parameter defined in Eq. (30), and $k \equiv k(q_1)$, $k' \equiv k'(q_1)$ are the standard elliptic modular functions, see e.g. [75]. The quantities $k$ and $k'$ are simply related to the basic physical parameters $\gamma$ and $h$. Indeed, one has that

$$k \equiv \begin{cases} \sqrt{(h/2)^2 + \gamma^2 - 1} / \gamma, & \text{Case 1a: } 4(1 - \gamma^2) < h^2 < 4; \\
\sqrt{(1 - h^2/4 - \gamma^2) / (1 - h^2/4)}, & \text{Case 1b: } h^2 < 4(1 - \gamma^2);
\end{cases}$$

$$k' \equiv \sqrt{1 - k^2}.$$  

By standard techniques of the theory of elliptic functions, equation Eq. (30) can be transformed into the following representation for the module $\tau_0$ as a function of $k$.

$$\tau_0 \equiv \frac{I(k')}{I(k)}, \quad k' = \sqrt{1 - k^2}, \quad (101)$$

$I(k)$ is the complete elliptic integral of the first kind,

$$I(k) = \int_0^1 \frac{dx}{\sqrt{(1 - x^2)(1 - k^2 x^2)}}. \quad (102)$$

The $q$-products in Eq. 97 and Eq. 99 can be expressed in terms of the elliptic lambda function or $\lambda$ - modular function. The $\lambda$ - function plays a central role in the theory of modular functions and modular forms, and it is defined by the equation (see e.g. [75]),

$$\lambda(\tau) = \frac{\theta_3(0|\tau)}{\theta_3(0|\tau)} \equiv k^2(e^{i\pi \tau}), \quad \Im \tau > 0, \quad (103)$$

where $\theta_j(s|\tau)$, $j = 3, 4$ are Jacobi theta-functions; the function $\theta_3(s|\tau)$ has already been defined in Eq. 31, while the function $\theta_4(s|\tau)$ is defined by the equation,

$$\theta_4(s|\tau) = \sum_{n=-\infty}^{\infty} (-1)^n e^{\pi i s n^2 + 2\pi i s n}. \quad (104)$$

The $\lambda$ - function is analytic function of $\tau$, $\Im \tau > 0$, and it satisfies the following symmetry relations with respect to the actions of the generators of the modular group,

$$\lambda(\tau + 1) = \frac{\lambda(\tau)}{\lambda(\tau) - 1}, \quad (105)$$

$$\lambda \left(-\frac{1}{\tau}\right) = 1 - \lambda(\tau). \quad (106)$$

In terms of the $\lambda$ - modular function, the formulae for Renyi read as follows [33].

$$S_R(\rho_A, \alpha) = \frac{1}{6} \frac{\alpha}{1 - \alpha} \ln (k' k) - \frac{1}{12} \frac{1}{1 - \alpha} \ln \left(\lambda(\alpha \tau_0)(1 - \lambda(\alpha \tau_0))\right) + \frac{1}{3} \ln 2, \quad (107)$$
for $h > 2$ and
\[
S_R(\rho_A, \alpha) = \frac{1}{6} \frac{\alpha}{1 - \alpha} \ln \left( \frac{k'}{k^2} \right) + \frac{1}{12} \frac{1}{1 - \alpha} \ln \left( \frac{\lambda^2(\alpha \tau_1)}{\lambda(\alpha \tau_0)} \right) + \frac{1}{3} \ln 2,
\]
(108)
for $h < 2$.

Eqs. 107 and 108 allow to apply to the study of the Renyi entropy the apparatus of the theory of modular functions.

**Remark.** Using Eq. 107 and Eq. 108 one can evaluate the asymptotics of the Renyi entropy as $\alpha \to 1$. This would lead to the following formulae for the Neumann entropy,

\[
S(\rho_A) = \frac{1}{6} \left[ \ln \left( \frac{k^2}{16k'} \right) + (1 - k^2) \frac{4I(k)I(k')}{\pi} \right] + \ln 2,
\]
(109)
in Case 1, and

\[
S(\rho_A) = \frac{1}{12} \left[ \ln \left( \frac{16}{k^2k'^2} \right) + (k^2 - k'^2) \frac{4I(k)I(k')}{\pi} \right],
\]
(110)
in Case 2. For the Cases 1a and 2 these formulae were first obtained by Peschel in [65] by a direct summation of series (90).

### 7 Spectrum of the limiting density matrix

We will show now, following [34], how to extract from Eq. (97) and (99) the information about the spectrum of the density matrix $\rho_A$.

Consider first the case $h > 2$. Combining equations (97) and (93), we arrive at the following representation for the $\zeta$-function $\zeta_{\rho_A}(\alpha)$,

\[
\zeta_{\rho_A}(\alpha) = e^{\alpha \left( \frac{\pi \tau_0 + \pi \ln k'}{12} \right)} \prod_{n=0}^\infty \left( 1 + q_n^{2n+1} \right)^2.
\]
(111)

At the same time, using the classical arguments of the theory of partitions (see e.g. [2], Chapter 11, equation (11.1.4)) we have that

\[
\prod_{n=0}^\infty (1 + q_n^{2n+1}) = \sum_{n=1}^\infty p_O^{(1)}(n) q^n,
\]
(112)

where $p_O^{(1)}(n)$, for $n > 1$, denote the number of partitions of $n$ into distinct positive odd integers, i.e.

\[
\# \{(m_1, ..., m_k) : m_j = 2r_j + 1, \quad m_1 > m_2 > ... > m_k, \quad n = m_1 + m_2 + ... + m_k \}.
\]

Hence (111) becomes,

\[
\zeta_{\rho_A}(\alpha) = e^{\alpha \left( \frac{\pi \tau_0 + \pi \ln k'}{12} \right)} \sum_{n=0}^\infty a_n q^n,
\]
(113)
where,
\[ a_0 = 1, \quad a_n = \sum_{l=0}^{n} p^{(1)}_N(l)p^{(1)}_N(n-l). \] 

(114)

Finally, observing that
\[ q^\alpha_n = (e^{-\pi\tau_0 n})^\alpha, \]
we conclude that
\[ \zeta_{\rho_A}(\alpha) = \sum_{n=0}^{\infty} a_n \lambda_n^\alpha, \quad \lambda_n = e^{-\pi\tau_0 n + \frac{1}{\alpha} + \frac{1}{\alpha} \ln \frac{k}{k'}}. \]

(116)

Comparing the last equation with equation (92) we arrive at the following theorem.

**Theorem 6.** ([34]) Let the magnetic field \( h > 2 \). Then, the eigenvalues of the reduced density matrix \( \rho_A \) are given by the equation,
\[ \lambda_n = e^{-\pi\tau_0 n + \frac{1}{\alpha} + \frac{1}{\alpha} \ln \frac{k}{k'}}, \quad n = 0, 1, 2, \ldots \]

(117)

and the corresponding multiplicities \( a_n \) are determined by the relation (114).

The case \( h < 2 \) is treated in a very similar way. Instead of (111) we have now the formula,
\[ \zeta_{\rho_A}(\alpha) = 2e^{\alpha(-\frac{\pi k}{12} + \frac{1}{\alpha} \ln \frac{k}{k'})} \prod_{n=0}^{\infty} (1 + q^\alpha_n)^2, \]

(118)

where \( q^\alpha \) as in (98). The analog of the Taylor expansion (112) is the equation,
\[ \prod_{n=0}^{\infty} (1 + q^2n) = \sum_{n=1}^{\infty} q^{2n}, \]

(119)

where \( p^{(1)}_{N}(0) = 1 \) and \( p^{(1)}_{N}(n) \), for \( n > 1 \), denote the number of partitions of \( n \) into distinct positive integers, i.e.
\[ \# \{(m_1, \ldots, m_k) : m_1 > m_2 > \ldots > m_k \geq 0, \quad n = m_1 + m_2 + \ldots + m_k\}. \]

Hence (118) becomes,
\[ \zeta_{\rho_A}(\alpha) = 2e^{\alpha(-\frac{\pi k}{12} + \frac{1}{\alpha} \ln \frac{k}{k'})} \sum_{n=0}^{\infty} b_n q^2n, \]

(120)

where,
\[ b_0 = 1, \quad b_n = \sum_{l=0}^{n} p^{(1)}_N(l)p^{(1)}_N(n-l). \]

(121)

Finally, observing that
\[ q^3n = (e^{-2\pi\tau_0 n})^\alpha, \]

(122)
we conclude that

$$\zeta_{\rho_A}(\alpha) = 2 \sum_{n=0}^{\infty} b_n \lambda_n^{\alpha}, \quad \lambda_n = e^{-2\pi\tau_0 \frac{n}{6} + \frac{6}{4\pi^2} \ln \frac{k'}{4k}}, \quad (123)$$

Comparing the last equation again with Eq. 92 we arrive at the analog of Theorem 6 for the case $h < 2$.

**Theorem 7.** ([34]) Let the magnetic field $h < 2$. Then, the eigenvalues of the reduced density matrix $\rho_A$ are given by the equation,

$$\lambda_n = e^{-2\pi\tau_0 \frac{n}{6} + \frac{6}{4\pi^2} \ln \frac{k'}{4k}}, \quad n = 0, 1, 2, \ldots, \quad (124)$$

and the corresponding multiplicities equal $2b_n$ where the integers $b_n$ are determined by the relation (121).

Let

$$f(x) := \sum_{n=0}^{\infty} a_n x^n, \quad (125)$$

be the generating function for the coefficients $a_n$. Then, Eq. 107 and Eq. 93 in conjunction with the symmetry property (106) allow to analyze the asymptotic behavior of the function $f(x)$ generating function as $x \to 1$. In its turn, this fact yields the evaluation of the large $n$ asymptotics of the multiplicities $a_n$ (details are in [34]).

**Theorem 8.** Let $a_n$ be the multiplicities of the eigenvalues of the reduced density matrix for $h > 2$. Then their large $n$ behavior is given by the relation,

$$a_n \sim 2^{-3/2} 3^{-1/4} n^{-3/4} e^{\pi \sqrt{n}}, \quad n \to \infty. \quad (126)$$

### 8 Summary and Open Problems

We want to emphasize that the method described here also works for evaluation of correlation functions. For example space, time and temperature dependent correlation function of quantum spins was evaluated in [42]. The book [15] explains how to apply this method for calculation of correlation functions in Bose gas with delta interaction.

On the other hand there are still open problems. For example let us consider the XXZ model. The Hamiltonian can be written in terms of Pauli matrices $\sigma_n$:

$$H_{XXZ} = - \sum_{n=-\infty}^{\infty} \sigma_n^x \sigma_{n+1}^x + \sigma_n^y \sigma_{n+1}^y + \Delta \sigma_n^z \sigma_{n+1}^z \quad (127)$$

At $\Delta < -1$ the model has a gap and the ground state is anti-ferromagnetic. Challenging problem is to calculate the von Neumann entropy and Rényi entropy of large block of spins on the infinite lattice. It will be interesting to find the dependence of limiting entropy on $\Delta$.
