Abstract Recently several measurements in the neutral current sector $b \rightarrow s l^+ l^−$ ($l = e$ or $μ$) as well as in the charged current sector $b \rightarrow cτ\bar{ν}$ show significant deviations from their Standard Model predictions. It has been shown that two different new physics solutions can explain all the anomalies in $b \rightarrow s l^+ l^−$ sector. Both these solutions are in the form of linear combinations of the two operators $(\bar{s}_lγ^a P_L b)(\bar{μ}_γ a μ)$ and $(\bar{s}_lγ^α P_L b)(\bar{μ}_γ a γ_5 μ)$. We show that the longitudinal polarization asymmetry of the muons in $B_s^* → μ^+ μ^−$ decay is a good discriminant between the two solutions if it can be measured to a precision of 10%, provided the new physics Wilson coefficients are real. If they are complex, the theoretical uncertainties in this asymmetry are too large to provide effective discrimination. We also investigate the potential impact of $b \rightarrow cτ\bar{ν}$ anomalies on $b \rightarrow sτ^+τ^−$ transitions. We consider a model where the new physics contributions to these two transitions are strongly correlated. We find that the branching ratio of $B_s^* \rightarrow τ^+τ^−$ can be enhanced by three orders of magnitude.

1. In the decay $B \rightarrow K^*μ^+μ^−$, some of the angular observables [1–3] are found to be in disagreement with their respective SM predictions [4]. The main discrepancy is in the angular observable $P_5$, which is at the level of 4 $σ$.
2. The branching ratio of $B_s \rightarrow φμ^+μ^−$ and the corresponding angular observables also differ from their SM predictions [5,6] at 3.5 $σ$ level.
3. The SM predicts the ratio $R_K ≡ \Gamma(B^+ → K^μ^+μ^−)/\Gamma(B^+ → K^e^+e^−) \lesssim 1$. LHCb experiment measured this ratio in the $q^2 (q^2 = (p_B − p_K)^2)$ range $1.0 \leq q^2 \leq 6.0$ GeV$^2$ [7]. The measured value $0.745^{+0.074}_{−0.069} (stat.) ± 0.036 (syst.)$ deviates from the SM prediction by 2.6 $σ$ [8,9].
4. LHCb experiment also measured the ratio $R_{K^*} ≡ \Gamma(B^0 → K^0μ^+μ^−)/\Gamma(B^0 → K^{*0}e^+e^−)$ in two different $q^2$ ranges, $(0.045 \leq q^2 \leq 1.1$ GeV$^2$) (low $q^2$) and $(1.1 \leq q^2 \leq 6.0$ GeV$^2$) (central $q^2$). The SM predicts this ratio to be $\approx 1$ for all $q^2$ [8,9]. The measured values are $0.669^{+0.110}_{−0.070} (stat.) ± 0.024 (syst.)$ for low $q^2$ and $0.685^{+0.113}_{−0.069} (stat.) ± 0.047 (syst.)$ for central $q^2$ [10]. These differ from the SM prediction by 2.2 − 2.4 $σ$ and 2.4 − 2.5 $σ$ respectively.

The anomalies in $R_K$ and $R_{K^*}$, which are an indication of violation of lepton flavor universality (LFU) in the neutral current decays of $b$ quark, can be explained by new physics (NP) in either $b → se^+e^−$ or $b → sμ^+μ^−$ or both whereas the first two anomalies require NP in $b → sμ^+μ^−$. Two kinds of NP amplitudes in $b → se^+e^−$ transitions can account for the $R_K$ and $R_{K^*}$ anomalies. These are

- vector and/or axial-vector amplitudes which will have constructive interference with the SM amplitude. The magnitude of such amplitude should be about 10% of the SM amplitude.
- scalar, pseudoscalar or tensor amplitudes which do not interfere with the SM amplitude. A discussion of the most general NP contribution to $b → se^+e^−$ is beyond the scope of this paper.

In this work, we will consider NP amplitudes only in \( b \to s \mu^+ \mu^- \) transition, because they can explain all four anomalies in the FCNC decays of the \( B \) mesons. These amplitudes must have destructive interference with the SM amplitude so that the resulting values of \( R_K \) and \( R_{K^*} \) will be less than 1. That is, these NP amplitudes are constrained to be vector and/or axial-vector amplitudes. Several groups [11–20] have performed global fits to identify the Lorentz structure of the NP operators and to determine their Wilson coefficients (WCs) which can account for all the \( b \to s \mu^+ \mu^- \) anomalies. There are two distinct solutions, one with the operator of the form \( (\bar{\gamma}^3 P_L b)(\bar{\mu} \gamma_\mu \mu) \) and the other whose operator is a linear combination of \( (\bar{\gamma}^3 P_L b)(\bar{\mu} \gamma_\mu \mu) \) and \( (\bar{\gamma}^3 P_L b)(\bar{\mu} \gamma_\mu S \mu) \) [18]. These results satisfy the requirement that only vector (V) and/or axial-vector (A) NP operators are allowed.

It is interesting to look for new observables in the \( b \to s \mu^+ \mu^- \) sector in order to (a) find additional evidence for the existence of NP and (b) to discriminate between the two NP solutions. These observables may be related to the observed decay modes or may be associated with the decay modes yet to be observed such as \( B_s \to l^+ l^- \gamma \) [21].

The branching ratio of \( B_s^* \) meson to di-muons is one such observable which is yet to be measured. In the SM, this decay mode is not subject to helicity suppression [22], unlike \( B_s \to \mu^+ \mu^- \) [23]. Further, it is sensitive to the NP operators containing both V and A currents of leptons whereas \( B_s \to \mu^+ \mu^- \) is sensitive only to the latter. A model independent analysis of this decay was performed in Ref. [24] to identify the NP operators which can lead to a large enhancement of its branching ratio. It was found that such an enhancement is possible only with the constraints from the present \( b \to s \mu^+ \mu^- \) data. It would be desirable to construct a new observable related to this decay mode to see whether such an observable has the potential to discriminate between the two existing NP solutions in \( b \to s \mu^+ \mu^- \) transition.

In this work, we consider the longitudinal polarization asymmetry of muon in \( B_s^* \to \mu^+ \mu^- \) decay, \( \mathcal{A}_{L,P}(\mu) \). This asymmetry is theoretically clean because it has a very mild dependence on the decay constants unlike the branching ratio. We first calculate the SM prediction of \( \mathcal{A}_{L,P}(\mu) \) and then study its sensitivity to the two NP solutions.

As mentioned above, there are additional discrepancies in the CC decays of \( B \) mesons. Such decays are driven by \( b \to c \tau \bar{\nu} \) transition, which occurs at tree level in the SM. These discrepancies, which are listed below, are an indication of LFU violation in the charged current decays of \( b \) quark.

1. The current world average of the ratio \( R_D = \mathcal{B}(B \to D \tau \bar{\nu})/\mathcal{B}(B \to D[e/\mu] \bar{\nu}) \), measured by BaBar and Belle, deviates 2.3σ from the SM prediction [25].
2. There is a series of measurements of the ratio \( R_{D^*} = \mathcal{B}(B \to D^* \tau \bar{\nu})/\mathcal{B}(B \to D^*[e/\mu] \bar{\nu}) \) by BaBar, Belle and LHCb experiments. Recent world average of \( R_{D^*} \) shows a discrepancy with respect to the SM prediction at a level of 3.4σ. Including the measurement correlation between \( R_D \) and \( R_{D^*} \), the current experimental world averages of \( R_{D^*[\nu]} \) show a ~4σ deviation from the SM predictions [26].

The NP operators which can account for \( R_{D^*[\nu]} \) anomaly are identified in Ref. [27]. In Ref. [28] it was shown that there are only four independent NP solutions which can explain the present data in the \( b \to c \tau \bar{\nu} \) sector. Methods to discriminate between these NP solutions were suggested in Ref. [29]. The NP WCs of these solutions are about 10% of the SM values.

Since this transition occurs at tree level in the SM, it is very likely that the NP operators also occur at tree level. In the SM, the relation between the interaction eigenstates and mass eigenstates leads to the cancellation of FCNCs at tree level through GIM mechanism. However the relation between the interaction eigenstates of NP and the mass eigenstates need not be the same as that in the SM. In such a situation, the NP will lead to tree level neutral current \( b \to s l^+ l^- \) transitions. In Ref. [30], a model is constructed where the tree level FCNC terms due to NP are significant for \( b \to s \tau^+ \tau^- \) but are suppressed for \( b \to s l^+ l^- \) where \( l = e \) or \( l = \mu \). The branching ratios for the decay modes such as \( B \to K^{(*)+} \tau^+ \tau^- \), \( B_s \to \tau^+ \tau^- \) and \( B_s \to \phi \tau^+ \tau^- \) will have a large enhancement in this model [30]. In this work we study the effect of this NP on the branching ratio of \( B_s^* \to \tau^+ \tau^- \) and the \( \tau \) polarization asymmetry \( \mathcal{A}_{L,P}(\tau) \).

This paper is organized as follows. In Sect. 2, we obtain the theoretical expressions for the longitudinal polarization asymmetry of the final state leptons in \( B_s^* \to l^+ l^- \) decays, where \( l = e, \mu \) or \( \tau \). This is done for the SM and for the case of NP V and A operators. In Sect. 3, we obtain predictions of \( \mathcal{A}_{L,P}(\mu) \) in both the SM and the two NP solutions which explain all \( b \to s \mu^+ \mu^- \) anomalies. In the same section we study the impact of tree level NP of Ref. [30] on the branching ratio of \( B_s^* \to \tau^+ \tau^- \) and \( \mathcal{A}_{L,P}(\tau) \). Finally in the Sect. 4, we present our conclusions.

2 Calculation of longitudinal polarization asymmetry for \( B_s^* \to l^+ l^- \) decay

2.1 Longitudinal polarization asymmetry in the SM

The pure leptonic decay \( B_s^* \to l^+ l^- \) is induced by the quark level transition \( b \to s l^+ l^- \). In the SM the corresponding effective Hamiltonian is
and the decay rate is given by

\[
\Gamma_{SM} = \frac{\alpha_{em} G_F}{2\sqrt{2}\pi} V_{ts}^* V_{tb} \left[ 1 + \frac{2 m_b^2}{m_B^*} \right] \left[ C_{8}\, \frac{m_b}{m_B^*} + \frac{m_b}{m_B^*} C_{7} \right] \left[ |C_{10}|^2 \right].
\]

and the decay rate is found to be

\[
\Gamma_{SM} = \frac{\alpha_{em} G_F}{2\sqrt{2}\pi} V_{ts}^* V_{tb} \left[ 1 + \frac{2 m_b^2}{m_B^*} \right] \left[ C_{8}\, \frac{m_b}{m_B^*} + \frac{m_b}{m_B^*} C_{7} \right] \left[ |C_{10}|^2 \right].
\]

and the decay rate is given by

\[
\Gamma_{\pm} = \frac{\alpha_{em} G_F}{2\sqrt{2}\pi} V_{ts}^* V_{tb} \left[ 1 + \frac{2 m_b^2}{m_B^*} \right] \left[ C_{8}\, \frac{m_b}{m_B^*} + \frac{m_b}{m_B^*} C_{7} \right] \left[ |C_{10}|^2 \right].
\]

and the decay rate is found to be

\[
\Gamma_{SM} = \frac{\alpha_{em} G_F}{2\sqrt{2}\pi} V_{ts}^* V_{tb} \left[ 1 + \frac{2 m_b^2}{m_B^*} \right] \left[ C_{8}\, \frac{m_b}{m_B^*} + \frac{m_b}{m_B^*} C_{7} \right] \left[ |C_{10}|^2 \right].
\]

and the decay rate is given by

\[
\Gamma_{\pm} = \frac{\alpha_{em} G_F}{2\sqrt{2}\pi} V_{ts}^* V_{tb} \left[ 1 + \frac{2 m_b^2}{m_B^*} \right] \left[ C_{8}\, \frac{m_b}{m_B^*} + \frac{m_b}{m_B^*} C_{7} \right] \left[ |C_{10}|^2 \right].
\]
In Eqs. (9) and (10), we have used the abbreviations \( \mathcal{N} = \frac{a_{em} G_F^2}{128 \pi^3} |V_{tb} V_{ts}^*|^2 f_{B_s}^T \sqrt{m_{B_s}^2 - 4m_T^2} \). Using Eqs. (8), (9) and (10), we get the lepton polarization asymmetry to be

\[
\mathcal{A}_{L_P}^{\pm \text{SM}} = \mp \frac{2 \sqrt{1 - 4m_T^2/m_B^2}}{\left(1 + 2m_T^2/m_B^2\right) \left| C_{9}^{\text{eff}} + \frac{2m_b f_{B_s}^T}{m_{B_s}^2 f_{B_s}^T} C_{7}^{\text{eff}} \right|^2 + \left(1 - 4m_T^2/m_B^2\right) |C_{10}|^2}.
\]

(11)

2.2 Longitudinal polarization asymmetry in presence of NP

We now investigate the lepton polarization asymmetry in the presence of NP. As the NP solutions to the \( b \to s l^+ l^- \) anomalies are in the form of \( V \) and \( A \) operators, we consider the addition of these NP operators to the SM effective Hamiltonian of \( b \to s l^+ l^- \). Scalar and pseudo-scalar NP operators do not contribute to \( B_s^+ \to l^+ l^- \) decay because \( \langle 0 | s b | B_s^+ (p_{B_s}, \epsilon) \rangle = 0 \). The effective Hamiltonian now takes the form

\[
\mathcal{H}_{\text{eff}}(b \to s l^+ l^-) = \mathcal{H}_{\text{SM}} + \mathcal{H}_{\text{VA}},
\]

(12)

where \( \mathcal{H}_{\text{VA}} \) is

\[
\mathcal{H}_{\text{VA}} = \frac{\alpha_{em} G_F}{\sqrt{2} \pi} V_{ts} V_{tb}^* \left[ C_{9}^{NP} (\bar{s} r_{l} l) - C_{10}^{NP} (\bar{s} r_{l} l) \right] + C_{7}^{NP} (\bar{s} r_{l} l) \]

Here \( C_{9}^{NP} \) and \( C_{10}^{NP} \) are the NP Wilson coefficients. Within this NP framework, the branching ratio and \( \mathcal{A}_{L_P} \) are obtained to be

\[
\mathcal{B}(B_s^+ \to l^+ l^-) = \frac{a_{em}^2 G_F^2 f_{B_s}^T m_{B_s} \tau_{B_s}^*}{96 \pi^3} |V_{ts} V_{tb}^*|^2 \sqrt{1 - 4m_T^2/m_B^2} \times \left[ \left(1 + \frac{2m_T^2}{m_B^2}\right) |C_{9}^{\text{eff}} + \frac{2mb f_{B_s}^T}{m_{B_s}^2 f_{B_s}^T} C_{7}^{\text{eff}} + C_{9}^{NP}|^2 \right] + \left(1 - \frac{4m_T^2}{m_B^2}\right) |C_{10} + C_{10}^{NP}|^2 \right],
\]

(13)

\[
\mathcal{A}_{L_P}^{\pm \text{NP}} = \mp \frac{2 \sqrt{1 - 4m_T^2/m_B^2}}{\left(1 + 2m_T^2/m_B^2\right) \left| C_{9}^{\text{eff}} + \frac{2m_b f_{B_s}^T}{m_{B_s}^2 f_{B_s}^T} C_{7}^{\text{eff}} + C_{9}^{NP}\right|^2 + \left(1 - 4m_T^2/m_B^2\right) |C_{10} + C_{10}^{NP}|^2}.
\]

(14)

3 Results and discussion

3.1 \( \mathcal{A}_{L_P}(\mu) \) with NP solutions

In this section we first calculate \( \mathcal{A}_{L_P}(\mu) \) for the \( B_s^+ \to \mu^+ \mu^- \) decay. The numerical inputs used for this calculation are listed in Table 1. The SM prediction is

\[
\mathcal{A}_{L_P}(\mu)|_{\text{SM}} = -\mathcal{A}_{L_P}(\mu)|_{\text{NP}} = 0.9955 \pm 0.0003.
\]

(15)

The uncertainty in this prediction (about 0.03%) is much smaller than the uncertainty in the decay constants (about 2%), making it theoretically clean.

Among the two NP solutions which can account for all the \( b \to s \mu^+ \mu^- \) anomalies [11, 18], only \( C_{9}^{NP}(\mu\mu) \) is non-zero for the first solution whereas \( C_{9}^{NP}(\mu\mu) \) and \( C_{10}^{NP}(\mu\mu) \) are equal and opposite for the second solution. In Table 2 we have listed the NP WCs of these solutions along with the predictions of \( \mathcal{A}_{L_P}(\mu) \) for them.

From this table it is obvious that the prediction of \( \mathcal{A}_{L_P}(\mu) \) for the first solution deviates from the SM at the level of 3.4\( \sigma \) whereas, for the second solution, it is the same as that of the SM. Hence any large deviation in this asymmetry can only be due to the first NP solution. We also provide the predictions for \( \mathcal{B}(B_s^+ \to \mu^+ \mu^-) \) in Table 2. It is clear that neither of the two solutions can be distinguished from each other or from the SM via the branching ratio.
Table 2  New physics predictions of branching ratio and $\mathcal{A}_{LP}(\mu)$ for $B_s^+ \rightarrow \mu^+\mu^-$ decay with real NP WCs

| NP type          | SM | NP WCs | $\mathcal{B}(B_s^+ \rightarrow \mu^+\mu^-)$ | $\mathcal{A}_{LP}(\mu)$ |
|------------------|----|--------|-------------------------------------------|-------------------------|
| $C_9^{NP}(\mu\mu)$ | 0  | -1.25 ± 0.19 | (1.10 ± 0.60) × 10^{-11} | 0.9955 ± 0.0003 |
| $C_9^{NP}(\mu\mu)$ | -$C_{10}^{NP}(\mu\mu)$ | -0.68 ± 0.12 | (0.79 ± 0.43) × 10^{-11} | 0.9936 ± 0.0057 |

Table 3  New physics predictions of branching ratio and $\mathcal{A}_{LP}(\mu)$ for $B_s^+ \rightarrow \mu^+\mu^-$ decay with complex NP WCs. The NP WCs are taken from Ref. [19]

| NP Type          | [Re(WC), Im(WC)] | $\mathcal{B}(B_s^+ \rightarrow \mu^+\mu^-)$ | $\mathcal{A}_{LP}(\mu)$ |
|------------------|------------------|-------------------------------------------|-------------------------|
| $C_9^{NP}(\mu\mu)$ | (-1.1 ± 0.2, 0.0 ± 0.9) | (0.85 ± 0.27) × 10^{-11} | 0.91 ± 0.13 |
| $C_9^{NP}(\mu\mu)$ | ($\tau\tau$) | (0.80 ± 0.27) × 10^{-11} | 0.99 ± 0.02 |

In the discussion above, the NP WCs are assumed to be real. If these WCs are complex, they can lead to various CP asymmetries in $B \rightarrow (K, K^*)\mu^+\mu^-$ decays [36]. These asymmetries can distinguish between the two NP solutions. In Ref. [19], it was assumed that $C_9^{NP}(\mu\mu)$ and $C_{10}^{NP}(\mu\mu)$ are complex and a fit to all the $b \rightarrow s \mu^+\mu^-$ data was performed. The resulting values of NP WCs from this fit are given in Table 3. The predictions for $\mathcal{B}(B_s^+ \rightarrow \mu^+\mu^-)$ and $\mathcal{A}_{LP}(\mu)$ are also given in this table. Because of the large uncertainties, neither of these two observables can distinguish between the two NP solutions. However, it is possible to make a distinction based on the CP asymmetries mentioned above [19].

3.2 Effect of NP in $B_s^+ \rightarrow \tau^+\tau^-$

As mentioned in the introduction, anomalies are also observed in the $b \rightarrow c\tau\bar{\nu}$ transitions. An NP model, which can account for these anomalies, is likely to contain NP amplitude for $b \rightarrow s\tau^+\tau^-$ transition also. Hence the branching ratio of $B_s^+ \rightarrow \tau^+\tau^-$ and $\tau$ longitudinal polarization asymmetry $\mathcal{A}_{LP}(\tau)$ will contain signatures of such NP. In the SM, the predictions for these quantities are

$$\mathcal{B}(B_s^+ \rightarrow \tau^+\tau^-) = (6.87 ± 4.23) \times 10^{-12},$$

$$\mathcal{A}_{LP}(\tau)|_{SM} = -\mathcal{A}_{LP}(\tau)|_{SM} = 0.8860 ± 0.0006.$$

The authors of Ref. [30] constructed a model of NP which accounts for the anomalies in $b \rightarrow c\tau\bar{\nu}$. This model contains tree level FCNC terms for $b \rightarrow s\tau^+\tau^-$ but not for $b \rightarrow s\mu^+\mu^- (l = e, \mu)$. Therefore, the WCs $C_9^{NP}(\mu\mu)$ and $C_{10}^{NP}(\mu\mu)$ have no relation to the WCs $C_9^{NP}(\tau\tau)$ and $C_{10}^{NP}(\tau\tau)$. The amplitude for $b \rightarrow s\mu^+\mu^-$ transition remains small enough that the constraints from $R_K$ and $R_K^*$ are satisfied. The WCs for the $b \rightarrow s\tau^+\tau^-$ transition have the form

$$C_9(\tau\tau) = C_9^{SM} - C_9^{NP}(\tau\tau),$$

$$C_{10}(\tau\tau) = C_{10}^{SM} + C_9^{NP}(\tau\tau),$$

in this model, where

$$C_9^{NP}(\tau\tau) = \frac{2\pi}{\alpha} \frac{V_{cb}}{V_{tb}V_{ts}^*} \left( \sqrt{\frac{R_X}{R_X^{SM}}} - 1 \right),$$

The ratio $R_X/R_X^{SM}$ is the weighted average of current experimental values of $R_D, R_D^*$ and $R_{J/\psi}$. From the current measurements of these quantities, we estimate this ratio to be $\simeq 1.22 ± 0.06$. This, in turn, leads to $C_9^{NP}(\tau\tau) \sim 0(100)$. Thus the NP contribution completely dominates the WCs and leads to greatly enhanced branching ratios for various $B/B_s$ meson decays involving $b \rightarrow s\tau^+\tau^-$ transition [30].

We calculate $\mathcal{B}(B_s^+ \rightarrow \tau^+\tau^-)$ and $\mathcal{A}_{LP}(\tau)$ as a function of $R_X/R_X^{SM}$. The plot of $\mathcal{B}(B_s^+ \rightarrow \tau^+\tau^-)$ vs. $R_X/R_X^{SM}$ is shown in left panel of Fig. 1. We note, from this plot, that $\mathcal{B}(B_s^+ \rightarrow \tau^+\tau^-)$ can be enhanced up to $10^{-9}$ which is about three orders of magnitude larger than the SM prediction. The plot of $\mathcal{A}_{LP}(\tau)$ vs. $R_X/R_X^{SM}$ is shown in the right panel of Fig. 1. It can be seen that $\mathcal{A}_{LP}(\tau)$ is suppressed by about 5% in comparison to its SM value.

The recent data on $R_{D^{(*)}}$ show less tension with the SM which leads to smaller values of $R_X/R_X^{SM}$. As long as this ratio is greater than 1.05, the branching ratio of $B_s^+ \rightarrow \tau^+\tau^-$ is enhanced by an order of magnitude at least. When $R_X/R_X^{SM} \sim 1.01$, $\mathcal{A}_{LP}(\tau)$ exhibits some very interesting behaviour. In this case, the tree level FCNC NP contribution is similar in magnitude to the SM contribution (which occurs only at loop level). Due to the interference between these two amplitudes, $\mathcal{A}_{LP}(\tau)$ changes sign and becomes almost $-1$. Hence a measurement of this asymmetry provides an effective tool for the discovery of tree level FCNC amplitudes of this model [30] when their magnitude becomes quite small.
4 Conclusions

There are several measurements in the decays induced by the quark level transition $b \to s l^+ l^-$ which do not agree with their SM predictions. All these discrepancies can be explained by considering NP only in $b \to s l^+ l^-$ transition. These NP operators are required to have $V$ and/or $A$ form to account for the fact that $R_K$ and $R_{K^*}$ are less than 1. A global analysis of all the measurements in $b \to s l^+ l^-$ sector leads to only two NP solutions. The first solution has $C_{N}^{0}(\mu \mu) < 0$ and the second has $C_{NP}^{0}(\mu \mu) = -C_{NP}^{0}(\mu \mu) < 0$. In this work we consider the ability of the muon longitudinal polarization asymmetry in $B_s^0 \to \mu^+ \mu^-$ decay to distinguish between these two solutions. This observable is theoretically clean because it has only a very mild dependence on the decay constants. For the case of real NP WCs, we show that this asymmetry has the same value as the SM case for the second solution but is smaller by 11% for the first solution. Hence, a measurement of this asymmetry to 10% accuracy can distinguish between these two solutions. But for the complex NP WCs, the discrimination power is lost because of the large theoretical uncertainties.

Furthermore, we study the impact of the anomalies in $b \to c \tau \bar{\nu}$ transitions on the branching ratio of $B_s^0 \to \tau^+ \tau^-$ and $\mathcal{A}_{LP}(\tau)$. In Ref. [30], a model was constructed where tree level NP leads to both $b \to s \tau^+ \tau^-$ and $b \to c \tau \bar{\nu}$ with moderately large NP couplings. Within this NP model, we find that the present data in $R_{D^{(*)}, J/\psi}$ sector imply about three orders of magnitude enhancement in the branching ratio of $B_s^0 \to \tau^+ \tau^-$ and a 5% suppression in $\mathcal{A}_{LP}(\tau)$ compared to their SM predictions. We also show that $\mathcal{A}_{LP}(\tau)$ undergoes drastic changes when the NP amplitude is similar in magnitude to the SM amplitude.

To measure $\mathcal{A}_{LP}(\mu)$ or $\mathcal{A}_{LP}(\tau)$ in experiments, the final state leptons have to decay into secondary particles. But for muon, the measurement would be quite difficult as it does not decay within the detector. In the case of $\mathcal{A}_{LP}(\tau)$, it may be possible for LHCb to reconstruct $\tau$ where the $\tau$ decays into multiple hadrons. This technique has been already used to identify the $\tau$ leptons in $B \to D^+ \tau \bar{\nu}$ decay. Therefore a precise reconstruction from the decay products of the $\tau$ is necessary to measure the $\tau$ longitudinal polarization asymmetry in $B_s^0 \to \tau^+ \tau^-$.
