INTRODUCTION

The inositol 1,4,5-trisphosphate receptors (IP₃Rs) are intracellular Ca²⁺ channels localized at the endoplasmic reticulum and regulate the spatio-temporal change of intracellular Ca²⁺ concentration, which are important for diverse physiological phenomena including gene expression, development, growth, neural plasticity, and secretion (Berridge et al., 2000). There are three subtypes of IP₃R in mammals and each IP₃R isoform exhibits a distinct expression pattern in vivo. Among the three subtypes, the type 1 IP₃ receptor (IP₃R1) is a brain dominant subtype (Foskett et al., 2007; Mikoshiba, 2007). We have previously showed that mice lacking the IP₃R1 receptor (Itrp1⁻/⁻) exhibit ataxia and seizure-like posture with multiple abnormal movements such as repetitive rigid posture, opisthotonic, tonic contractions of the neck and trunk, and premature death around the third week after birth (Matsumoto et al., 1996). However, since IP₃R1 is expressed in a wide range of brain regions including cerebellum, cerebral cortex, hippocampus, and striatum, the particular neural activities and circuits causing these involuntary movements in the Itrp1⁻/⁻ mice remain unknown.

Dystonia is a neurological disorder in which sustained muscle contractions induce twisting and repetitive movements of abnormal posturing. Simultaneous abnormal contractions of agonistic and antagonistic muscles (co-contractions) are one of the most distinct features of dystonic movements. Because of various phenotypic and genotypic subtypes in dystonia, its pathogenic mechanisms remain elusive. Traditionally, dystonia has been thought to be a basal ganglia (BG) disorder (Marsden and Quinn, 1990; Lenz et al., 1998; Vitek et al., 1999; Zhuang et al., 2004; Chiken et al., 2008; Nambu et al., 2011). In contrast, recent accumulating evidence has further suggested abnormalities of the cerebellum and brainstem in some dystonic patients (Ceballos-Baumann et al., 1995; Eidelberg et al., 1998; Mazzotta et al., 1998; Odgren et al., 1998; Hutchinson et al., 2000). Several animal models of dystonia also exhibit cerebellar abnormalities (Ledoux and Lorden, 2002; Pizoli et al., 2002; Raike et al., 2005; Walter et al., 2006; Chen et al., 2009; Calderon et al., 2011; Ledoux, 2011; Filip et al., 2013) and aberrant cerebellar activities in dystonic model animals were reported (Ledoux and Lorden, 2002; Walter et al., 2006; Chen et al., 2009), however, little is known about firing patterns of Purkinje cell (PC) activity associated with particular dystonic movements of freely moving mice. At the neural circuit level, it was suggested that cerebellar outputs alter BG activity thereby leading...
Hisatsune et al. BG-independent dystonia by IP3R1 deletion

... to dystonic movements (Neychev et al., 2008; Calderon et al., 2011).

In this study, we showed that genetic deletion of IP3R1 within the cerebellum and brainstem is sufficient to cause dystonia in mice. Although in the previous report we described epileptic-like seizures in Itpr1−/− mice, in the current study we concluded that the behavior of Itpr1−/− mice is better described as dystonia with severe ataxia because there was no abnormal electroencephalogram activity during the seizure-like posture (Figure 1A). In addition, we revealed distinct patterns of PC firing that were tightly coupled to the dystonic movements in freely moving mutant mice. We also showed that pharmacological inactivation of the cerebellum or inferior olive (IO), but not BG, and deletion of PCs ameliorate the dyskinesia. Thus, our mutant mice provide a therapeutic dystonia model solely dependent upon abnormal olivocerebellar pathways and provide a coherent mechanism for a specific type of dystonia.

**MATERIALS AND METHODS**

**MICE**

For generation of conditional Itpr1 knockout mice, the floxed Itpr1 mice (Sugawara et al., 2013) were crossed with Wnt1 promoter-Cre (Danielian et al., 1998), Emx1-Cre (Iwasato et al., 2000), and Gpr88-Cre transgenic (Tg) mice (Hisatsune et al., 2013). Genotyping of Lurcher mice was performed as previously (Nishiyama et al., 2010). Body size/weight of Emx1-Cre;Itpr1flox/flox and Gpr88-Cre;Itpr1flox/flox was indistinguishable from that of control mice. The conditional mice lacking IP3R1 in the cerebellum/brainstem (Wnt1-Cre;Itpr1flox/flox mice) were severely dystonic and could not take in enough food to survive, so...
they were hand-fed a nutritionally complete soft diet, DietGel76A (ClearH2O), for their entire lives after weaning. All animals were ethically treated according to the guideline of Animal Experiments Committee of RIKEN Brain Science Institute.

**HISTOLOGY AND IN-SITU HYBRIDIZATION**

The mice brains (18- to 20-day-old Itpri1−/− and littermate Itpri1+/+ mice; 8-week-old Wnt1-Cre;Itpri1floxflo and Itpri1floxflo mice; and 23-day-old mice for Lurcher experiments) were transcardially perfused with 4% PFA in PBS. The fixed brains were immersed in 30% sucrose in PBS for O/N at 4°C. The brains were quickly frozen in Tissue-Tek compound (SAKURA, Japan), and cryostat sections (12 μm thick) were made.

For immunohistochemistry, the sections were permeabilized with 0.25% Triton/PBS for 5 min and immersed with boiled acetate buffer (10 mM, pH 6.0) for 10 min. After blocked, the sections were probed with the indicated primary antibodies (anti-IP3R1 antibodies (18A10, 50 μg/ml), rabbit anti-Tyrosine hydroxylase (TH) antibodies (1.0 μg/ml), rabbit anti-Homer 3 S120 antibody, and guinea pig anti-Homer 3 antibodies) for ON and 4°C. After washed with PBS, the sections were probed with Alexa 594-conjugated goat anti-rabbit IgG, Alexa 488-conjugated anti-guinea pig IgG, and Alexa 488-conjugated goat anti-rat IgG (Invitrogen) for 1 h at RT. The coverslips were mounted with Vectashield (Vector Laboratories) and observed under fluorescence microscopy E600 (Nikon).

For in-situ hybridization, frozen (12 μm thick) or paraffin-embedded (5 μm thick) sections of 18- to 20-day-old Itpri1−/− and Itpri1+/+ mice or 8-week-old and 19-day-old Wnt1-Cre;Itpri1floxflo and Itpri1floxflo mice were treated with proteinase K (1 μg/ml, Wako) for 10 min at RT. The sections were blocked and probed with sense and antisense cFos probes for ON at 68°C. The cFos fragment was amplified with primers, sense primer: 5′-CCGAATTCTAGATGTTTTCGGGTTC TCAAGG-3′, anti-sense primer: 5′-CCTACGCTTTCAGGGG CAGCAGGTG-3′. The underlines indicate EcoRI and HindIII sites for cloning the amplified cFos fragment to the Bluescript II vector.

**IMMUNOBLOTTING**

To analyze the expression of IP3R1 and TH, various parts of the 8-week-old brain were excised and were sonicated in a Sucrose buffer and used for western blotting. Antibodies were rabbit polyclonal anti-TH antibody (1.0 μg/ml, Chemicon), mouse monoclonal anti-β-actin antibody (1.0 μg/ml Sigma), rat monoclonal anti-IP3R1 antibody (18A10: 1.0 μg/ml), and rabbit anti-cFos antibody (1.0 μg/ml, Santa cruz).

**CYTCHROME OXIDASE (CO) STAINING**

Frozen 4%PFA-fixed 8-week-old brain sections (100 μm thick) were incubated in 0.1 M phosphate buffer containing 4 g sucrose, 50 mg of cytochrome C, and 50 mg of diaminobenzidine per 100 ml of buffer at 37°C for 1–2 h. To compare the CO staining intensities among different genotypes of mice, brains were fixed, cut, and reacted with the same solutions, and the digital photographs were taken on a same day.

**ADMINISTRATION OF DRUGS INTO THE MOUSE BRAIN (CEREBELLUM, INFERIOR OLIVE, AND BASAL GANGLIA)**

Mice (~2 month-old) were anesthetized with 1.5% halothane anesthesia with N2O:O2 (3:2) ventilation. A guide cannula (C313, inner diameter: 0.39 mm, outer diameter: 0.71 mm, Plastics One) was implanted at the middle of vermis of cerebellum (1.1 mm in depth). After 3 days of recovery, an internal cannula (1.0 mm projection length from the guide cannula) was replaced with the dummy cannula and PBS or CNQX (5 mM in PBS, Tocris) was infused into the cerebellum at the speed of 0.5 μl/min for 20 min. The same guide cannula system was used for lidocaine (4.0% in PBS, MP Biomedicals) injection into the IO (the tip of the cannula was targeted to just above the medial nuclei) and bilateral BG (entopeduncular nucleus, 1.3 mm posterior to the Bregma, lateral to 2.2, 4.5 mm depth).

**ELECTROPHYSIOLOGICAL RECORDINGS USING ACUTE CEREBELLAR SLICE**

Cerebellar slices were prepared from Itpri1+/+ and Itpri1−/− mice (P17-20). Parasagittal slices (230 μm thick) of the cerebellar vermis were cut using a vibrating microtome (VT1000S, Leica, Nussloch, Germany) in an ice-cold extracellular solution containing (in mM) 252 sucrose, 3.35 KCl, 21 NaHCO3, 0.6 Na2PO4, 9.9 glucose, 1 CaCl2, and 3 MgCl2 and gassed with a mixture of 95% O2 and 5% CO2 (pH 7.4). The slices were maintained at RT for at least 1 hr in a holding chamber, where they were submerged in artificial cerebrospinal fluid (ACSF) containing (in mM) 138.6 NaCl, 3.35 KCl, 21 NaHCO3, 0.6 Na2PO4, 9.9 glucose, 2 CaCl2, and 1 MgCl2 (bubbled with 95% O2 and 5% CO2 to maintain the pH at 7.4).

PCs were visually identified under Nomarski optics using a water immersion microscope (BX51WI, Olympus, Japan). For loose cell-attached recording, the pipette was gently placed in contact with a cell body of PC, and slight suction was applied. The pipette (2–4 MΩ) containing ACSF was maintained at 0 mV. The membrane currents were recorded using an amplifier, MultiClamp 700B (Molecular Devices, Foster City, CA, USA) and pCLAMP9.2 software (Molecular Devices), digitized, and stored on a computer disk for off-line analysis. All signals were filtered at 2 kHz and sampled at 5–10 kHz. All experiments were performed at 31–32°C. Action potential frequencies were analyzed using the Mini analysis program, version 6 (Synaptosoft, Decatur, GA, USA) and Kynplot 5.0 (Kyence, Tokyo, Japan).

**EXTRACELLULAR RECORDING IN ANESTHETIZED MICE**

Recordings were performed in anesthetized mice (1–2 months old) after an intraperitoneal injection of 50 mg/kg Nembutal
using 1.5% halothane anesthesia with N₂O:O₂ (3:2) ventilation. Additional doses of 0.15–0.25 mg were given if necessary to maintain anesthetic level. A sedative, chlorpromazine (0.2 mg, i.m.), was administered to supplement of the Nembutal. Atropine (0.3 mg, s.c.) and dexamethasone (0.05 mg, s.c.) were injected subcutaneously (Gordon and Stryker, 1996). The animal’s temperature was maintained at 38°C. The heart rate was monitored continuously.

A small hole (1.0 mm) was drilled in the occipital bone above the cerebellar vermis of lobule IV (midline, 4.5 mm caudal from lambda), and the dura was exposed and covered with warm agarose (2.8% in saline). The microelectrode tip (epoxy-coated tungsten microelectrodes, 9–12 MΩ impedance; FHC, ME) was positioned above the small hole and advanced into the cerebellar lobule IV vermis using a stepping motor controlled micromanipulator. Raw signals from the electrodes were amplified, filtered (0.3–5 kHz), digitized at 25 kHz and stored (LabVIEW, National Instrument, Austin, TX). Single and multiunit PC activities (peak positions above the 6 sigma noise level) were isolated by off-line spike sorting (Offline sorter, Plexon, Dallas, TX). Simple spikes (SSs) and complex spikes (CSs) were identified based on their characteristic waveforms.

**EEG, EMG RECORDING**

A stainless screw electrode for EEG recording was secured over the cerebellar cortex (2.0 mm posterior to the lambda, on the midline) and a reference screw electrode was placed over the somatosensory (1.5 mm lateral to the midline, 1.0 mm posterior to the bregma) or frontal cortex (1.0 mm lateral to the midline, 2.0 mm anterior to the bregma) (Miyamoto et al., 2012). A stainless wire was inserted in the neck muscle for EMG recording. Polygraphic signals (band-pass filtered at 0.7–170 Hz) were amplified by telemetry system (Data Sciences International, St. Paul, MN) and sampled at 500 Hz (SleepSign, KISSEI COMTEC, Japan). Based on polygraph and infra-red camera monitoring, sleep/waking behavioral state and epileptic EEG pattern was explored.

**EXTRACELLULAR RECORDING FROM BEHAVING MICE**

The tetrodes of four nichrome wires (13 μm) were stereotaxically implanted into the cerebellar vermis of lobule IV (6.25 mm posterior to the Bregma, on the midline). Signals from each electrode were band-pass filtered (1–6 kHz) and digitized at 25 kHz sampling frequency (Plexon, Dallas, TX). A reference electrode was chosen from electrodes which did not show neuronal activity. Neuronal spike data (firing rate, autocorrelogram, interspike interval) was analyzed by NeuroExplorer (Nex Technologies, Littleton, MA).

Similar to the recording of cerebellar PCs, tetrodes were implanted to monitor neuronal activity in the BG (caudate putamen and globus pallidus, 0.5 mm posterior to the Bregma, 2.0–3.0 mm lateral to the midline, 2.0–4.0 mm depth from the surface) during dystonic movements. Multi-unit neuronal activity data were sampled with a minimal interval of 200 μm by slowly advancing the tetrodes. For behavior analyses, we defined rigid posture as the duration in which mice hunched their backs and extended their paws to maintain the posture. In addition, we defined opisthotonus as an abnormal posture in which the mouse’s neck was completely held at the bridging position (i.e., bent fully toward the upper back). We judged the beginning of opisthotonus when the neck was held at the maximal bridging position, and defined the ending as its complete return to the normal (horizontal/unbent) position.

**Footprint analysis**

The hindpaws of 8-week-old Emx1-Cre;Itprr1flox/flox and Gpr88-Cre;Itprr1flox/flox mice, or of 19-day-old mice for Lurcher experiments, were dipped in non-toxic water-based black paint, and allowed to walk down an enclosed runway lined with white paper, to determine their gait characteristics.

**STATISTICAL ANALYSES**

The significance of differences between groups was analyzed using Student’s t-test, Mann-Whitney U-test, Dunnett’s test, or ANOVA followed by the Bonferroni’s test as appropriate. A value of P < 0.05 is reported as significant.

**RESULTS**

**ENHANCED PC ACTIVITY IN IP₃R1 DEFICIENT MICE**

To examine the neural activities and circuits causing the dyskinetic movements of Itprr1−/− mice in detail, we generated several brain-specific IP₃R1 conditional knockout mice: restricted to the dorsal telencephalon (Emx1-Cre;Itprr1flox/flox), the cerebellum/brainstem (Wnt1-Cre;Itprr1flox/flox), and to the BG (Gpr88-Cre;Itprr1flox/flox). Neither Emx1-Cre;Itprr1flox/flox mice, lacking IP₃R1 in excitatory neurons and glial cells of the cerebral cortex and hippocampus, nor Gpr88-Cre;Itprr1flox/flox mice, lacking IP₃R1 in striatal neurons, exhibited apparent dyskinesia like total Itprr1−/− mice (Figure 1B). The Emx1-Cre;Itprr1flox/flox and Gpr88-Cre;Itprr1flox/flox mice were born normally and showed normal growth patterns through adulthood. In striking contrast, Wnt1-Cre;Itprr1flox/flox mice began to show ataxia around postnatal day 9 (P9), and exhibited dyskinesia including opisthotonus, repetitive rigid posture, and tonic contractions of the neck and trunk as they grew beyond 2 weeks (Movie S1, and the footprint analyses shown in Figure 6B, left panel).

Unlike the premature death in Itprr1−/− mice, Wnt1-Cre;Itprr1flox/flox mice grew to adulthood by hand-feeding. Body weight of Wnt1-Cre;Itprr1flox/flox mice was about 45% of Itprr1−/− mice at 5 weeks. Cerebellar size of Wnt1-Cre;Itprr1flox/flox mice at 8 weeks was significantly smaller than that of Itprr1−/− mice, whereas cerebral cortex size was comparable (Figures 1C,D). The apparent morphological constituents of the cerebellum, such as granular layer, PC layer, and molecular layer seemed normal and no apparent cell death occurred as judged by DAPI staining for nuclear condensation. The expression level of IP₃R1 in the cerebellum of 8 week-old Wnt1-Cre;Itprr1flox/flox mouse was significantly lower than that of Itprr1−/− mice, whereas expression in the hippocampus, striatum, and cerebral cortex of Wnt1-Cre;Itprr1flox/flox mice was equivalent to that of Itprr1−/− mice (Figures 1E–G). Residual IP₃R1 expression in the cerebellum of the 8-week-old Wnt1-Cre;Itprr1flox/flox mice was attributed at least partly to PCs still expressing IP₃R1 protein after
Interestingly, we found strong expression in both PCs localized to the caudal parts of the cerebellum and hippocampus and cortex in either Itpr1+/− mice (Figure 1F) and proximal dendrites of PCs in 8-week-old Wnt1-Cre;Itpr1flox/flox mice. (D) Ectopic expression of tyrosine hydroxylase (TH) in PCs of 19-day-old Itpr1+/− mice. (E) The TH expression in coronal sections of the Wnt1-Cre;Itpr1flox/flox cerebellum at 8 weeks. (F) Banded patterns of TH expressing PC in the Wnt1-Cre;Itpr1flox/flox cerebellum at 8 weeks. (G) TH expression was not dependent on the IP3R1 expression of PCs in Wnt1-Cre;Itpr1flox/flox mice. (H) Intraperitoneal injection of harmaline (30 mg/kg) increased the signals for the Homer 3 phosphorylation of PCs of 8-week-old wild-type mice in a time dependent manner. (I) Intraperitoneal injection of harmaline increased the TH expression of PCs of wild-type mice after 24 h. All experiments were performed at least three times, and the representative data were shown.

Incomplete Cre/flox recombination in the PCs of the Wnt1-Cre Tg mice (Figures 1F, 2G).

To further delineate the neurons responsible for the expression of dystonia in Itpr1−/− and Wnt1-Cre;Itpr1flox/flox mice, we investigated the expression of cfos mRNA, a neural activity marker (Morgan et al., 1987). Interestingly, we found strong cfos mRNA expression in PCs localized to the caudal parts of the cerebellum in both Itpr1−/− and Wnt1-Cre;Itpr1flox/flox mice, but not in that of Itpr1+/+ or Itpr1flox/flox mice (Figures 2A,B, upper panels). No apparent elevation of cfos mRNA was observed in the hippocampus and cortex in either Itpr1−/− or Wnt1-Cre;Itpr1flox/flox mice (Figures 2A,B, lower panels). We also examined CaM kinase II-mediated phosphorylation levels of Homer 3 as a marker of PC depolarization (Mizutani et al., 2008). Only weak Homer 3 phosphorylation (S120) signals were observed in the soma and proximal dendrites of PCs in 8-week-old Itpr1flox/flox mice (Figure 2C), as reported previously (Mizutani et al., 2008). In 8-week-old Wnt1-Cre;Itpr1flox/flox mice, however, intense Homer 3 phosphorylation was observed at the soma and proximal dendrites, including the apical dendrites of PCs in caudal lobules 9 and 10 (Figure 2C, right).

In addition, we found aberrant tyrosine hydroxylase (TH) expression which is induced by cfos (Nagamoto-Combs et al., 1997) in the Itpr1−/− (Figure 2D) and Wnt1-Cre;Itpr1flox/flox PCs (Figure 2E). The TH-positive PCs were mainly observed in the vermis and floculus of the Wnt1-Cre;Itpr1flox/flox and Itpr1−/− cerebellum (Figure 2E) and were localized in a banded pattern (Figure 2F). In the wild-type cerebellum, we detected some TH-positive PCs as reported previously (Hess and Wilson, 1991). However, TH expression levels were relatively weak, and the
regions expressing TH in a banded manner were both fewer and smaller in size in the \textit{Itpr1}^{+/+} and \textit{Itpr1}^{floxflo} mice than in the \textit{Itpr1} mutant mice (Figure S1). Although PCs normally express a large amount of IP3R1 in the brain, the abnormal TH expression in the Wnt1-Cre;\textit{Itpr1}^{floxflo} cerebellum was observed in PCs regardless of IP3R1 expression (Figure 2G), suggesting that altered neural inputs onto PCs may trigger the aberrant TH expression.

Since climbing fibers (CF) innervate PCs localized within banded patterns (Oscarsson, 1979), olivocerebellar inputs may be the cause of abnormal involuntary movements in the Wnt1-Cre;\textit{Itpr1}^{floxflo} mice. Harmaline evokes synchronous firing across large populations of PCs via the olivocerebellar pathway by electrical coupling of IO neurons, resulting in the expression of tremor in mice (Hill and Sasaki, 1989). We intraperitoneally injected harmaline into wild-type mice and examined Homer 3 phosphorylation and TH expression in PCs. We found that IO activation rapidly increased the phosphorylation levels of Homer 3 in the soma and dendrites of PCs in a time dependent manner (Figure 2H). Intense phosphorylation signals were first observed in the soma of PCs within 15 min after injection (Figure 2H, arrow), then progressed into proximal and apical dendrites as time passed (Figure 2H, arrowhead). Furthermore, we observed elevation of TH signals in PCs at the caudal region of the cerebellum, especially lobules XI and X at 24 h after injection (Figure 2I). These results closely resembled those observed in the Wnt1-Cre;\textit{Itpr1}^{floxflo} mice. Therefore, we hypothesized that abnormal PC firing caused by excessive olivocerebellar input is the cause of involuntary movements in the \textit{Itpr1}^{−/−} and Wnt1-Cre;\textit{Itpr1}^{floxflo} mice.

**PC ACTIVITY CORRELATES WITH DYSTONIC MOVEMENTS OF MICE**

To reveal the nature of abnormal PC firing underlying the expression of dystonia in the \textit{Itpr1}^{−/−} mice, we first measured spontaneous PC activities by loose cell-attached recording using acute cerebellar slices, in which neuronal inputs from climbing and mossy fibers were severed. Because the PCs highly expressing TH were mainly observed in caudal parts of the cerebellar vermis of \textit{Itpr1}^{−/−} mice (Figure 2E), we measured spontaneous activities of PCs mainly from those areas. However, we found no apparent difference in spike frequency and coefficient of variation (CV) between PCs from wild-type and total \textit{Itpr1}^{−/−} mice under these conditions (Frequency: \textit{Itpr1}^{+/+}: 25.89 ± 2.89 (Means ± sem), n = 22 cells from 3 mice; \textit{Itpr1}^{−/−}: 28.86 ± 3.41, n = 26 from 3 mice, Student’s t-test: \textit{p} = 0.51. CV: \textit{Itpr1}^{+/+}: 0.23 ± 0.03, n = 22; \textit{Itpr1}^{−/−}: 0.22 ± 0.02, n = 26, Student’s t-test: \textit{p} = 0.72).

Since the cerebellar slice is devoid of neuronal inputs arising from other brain structures, we next asked whether spontaneous PC activities are altered in anesthetized mice. We performed extracellular recording of PC activities from caudal lobules in the cerebellar vermis (Figure 3A), which is responsible for the coordination of body trunk movement. We observed high amplitude PC spiking in both total \textit{Itpr1}^{−/−} and Wnt1-Cre;\textit{Itpr1}^{floxflo} mice as well as in wild-type mice (Figure 3B). Typical SSs and CSs were seen in both total \textit{Itpr1}^{−/−} and Wnt1-Cre;\textit{Itpr1}^{floxflo} mice as well as an indication of PC activity in vivo (Figure 3B). Spontaneous firing rates of Wnt1-Cre;\textit{Itpr1}^{floxflo} mice were decreased compared to \textit{Itpr1}^{floxflo} mice (\textit{Itpr1}^{floxflo}: 17.12 ± 1.61 (N = 5 mice, n = 37 cells); Wnt1-Cre;\textit{Itpr1}^{floxflo}: 12.84 ± 1.59 (N = 4, n = 55). Mann-Whitney U-test: *\textit{p} = 0.015*), and this tendency was also observed in total \textit{Itpr1}^{−/−} mice, although this was not significant \textit{Itpr1}^{+/+}: 26.01 ± 3.42 (N = 3, n = 28); \textit{Itpr1}^{−/−}: 19.95 ± 2.52 (N = 4, n = 25). Student’s t-test: \textit{p} = 0.169). The CVs were not significantly different between the groups \textit{Itpr1}^{floxflo}: 1.43 ± 0.18 (n = 37), Wnt1-Cre;\textit{Itpr1}^{floxflo}: 1.07 ± 0.08 (n = 55), Mann-Whitney U-test: \textit{P} = 0.083, \textit{Itpr1}^{+/+}: 1.30 ± 0.07 (n = 28), \textit{Itpr1}^{−/−}: 1.57 ± 0.26 (n = 25), Mann-Whitney U-test: \textit{P} = 0.91).

We also found that averaged auto-correlograms of PC activity in Wnt1-Cre;\textit{Itpr1}^{floxflo} mice lacked a peak around 0-100 ms compared to \textit{Itpr1}^{floxflo} mice (Figure 3C). The peak height (25-35 ms) was significantly lower than that of \textit{Itpr1}^{floxflo} mice: \textit{P} = 0.01, Figure 3C), suggesting an alteration of PC activity patterns caused by IP3R1 deletion. Given that the spontaneous activity pattern was little
affected in isolated cerebellar slices, these results suggest that neuronal inputs to PCs, such as parallel fiber or CF inputs, were changed by IP3R1 deletion in vivo.

Anesthetics influence synaptic neurotransmission or cellular communication (Keane and Biziere, 1987) and suppress animal behavior and movement. To gain more insight into the possible link between PC firing and the expression of dystonia, we recorded multiple unit activity of PCs from freely moving mice (Figure 4A). High amplitude putative PC spiking and low amplitude background activity were alternately recorded as the electrode advanced (400–800 μm). Multiple spiking and increased background activity of awake animals sometimes made discrimination between SSs and CSs difficult. In Itpr1<sup>flox/flox</sup> mice, putative PC activity showed regular tonic firing similar to the firing pattern of anesthetized mice (Figure 4A, lower right panel). We did not see a drastic change of firing rate associated with particular movements or behaviors in the caudal part of the vermis. Likewise, sleep-wake state associated changes of PC firing rate were not evident.

In contrast, a sharp increase of firing rates was observed intermittently (about once/10 s) in Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice and was tightly coupled to body movement related to paroxysmal dyskinesia (Figure 4A). Typically, Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice gradually increased rigidity during the low firing period (indicated by the orange bar in Figure 4A, lower right panel). Then, they abruptly extended their trunk and limbs simultaneously (Figure 4A, lower left panel) during the high frequency period (indicated by the blue bar). This sequence of high and low frequency firing recurred while the animal was awake, but not during stiff ambulation. Though clear isolation of CSs was difficult, CS activity prevailed during the rigid posture (the orange bar), while SS activity became dominant with high frequency firing during the body-extension (the blue bar) (Figure 4A, lower panels).

Interestingly, the intraperitoneal injection of harmaline (30 mg/kg) in awake wild-type mice reduced SS, and caused CS-dominant spike patterns in PCs (Figure 4B) reminiscent of their firing patterns in the Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice during rigid posture. When Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice fell asleep, these particular patterns of PC activity diminished. The frequency of CSs was significantly increased in behaving Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice as compared to Itpr1<sup>flox/flox</sup> mice, whereas the difference was not evident under anesthetized condition (Figure 4C). An increase of multuni activity corresponded to the body-extension phase (high firing rate period, blue arrowhead) as judged by an independent observer (Figure 4D). Multuni firing peaks in several recordings from lobules in caudal portions of the vermis were averaged (N = 4, 20 MUA recordings), and we confirmed distinct cerebellar activity changes associated with rigid and extended postures (Figure 4E).

TEMPORAL INACTIVATION OF THE CEREBELLUM AMELIORATES DYSTONIA

To confirm the involvement of cerebellar activity in the dystonic movements of Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice, we inhibited cerebellar activity by α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptor antagonist (CNQX) infusion. Inactivation of the cerebellum was confirmed by ataxia of CNQX-infused wild-type mice (Figure 5A), including abnormal footprints with shorter step length and wider gait after 2 h of infusion that recovered by 5 h (Figure 5A). Cerebellum specific infusion of the drug was confirmed by Fluoro Ruby (Figure 5B). No ataxic gait was observed in wild-type mice infused with saline. Strikingly, CNQX infusion into the cerebellum of Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice improved their voluntary movement significantly: dyskinesia such as opisthotonus, rigid posture, and tremor was abolished (Figures 5C,D). Although the mutant mice still showed ataxia, they exhibited partially restored gait within 2 h (Figures 5E,F, Movie S2). After 5 h, dystonic movements of Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice appeared.

GENETIC DELETION OF PCs RESCUES DYSTONIA OF Wnt1-Cre;Itpr1<sup>flox/flox</sup> MICE

To further explore the influence of cerebellar output from PCs on dystonic movements, we also genetically deleted PCs from the cerebellum of Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice by mating them with Lurcher mice (GluD2<sup>C/-</sup>) in which most of PCs die due to a mutation of the delta 2 glutamate receptor (GluD2) during the second postnatal week (Barmack and Yakhnitsa, 2003). Interestingly, we found that dystonic movements in Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice were completely abolished in GluD2<sup>C/-</sup>;Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice. The GluD2<sup>C/-</sup>;Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice greatly improved their gait to a level similar to those of GluD2<sup>C/-</sup> mice [Figures 6A,B, and Movie S3, N = 4. Stride length: GluD2<sup>C/-</sup>;Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice were 1.48 ± 0.053 and GluD2<sup>C/-</sup>;Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice: 1.60 ± 0.03 (Mean ± sem, Student’s t-test P = 0.06, n = 18 from 3 mice), base width: GluD2<sup>C/-</sup>;Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice: 1.03 ± 0.014 and GluD2<sup>C/-</sup>;Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice: 0.83 ± 0.043 (Mean ± sem, Student’s t-test P < 0.001, n = 12 from 3 mice). Loss of most of PCs were confirmed in the cerebellum of GluD2<sup>C/-</sup>;Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice (Figures 6C,D). These results strongly suggested that abnormal cerebellar output from PCs produces dystonia in mice lacking IP3R1.

OLIVO-CEREBELLAR PATHWAY, BUT NOT BG, IS INVOLVED IN THE EXPRESSION OF DYSTONIA

Because predominant CS activities prevailed during dystonic posture (Figure 4), we checked activities of IO neurons, which send CFs to PCs, by a cytochrome oxidase (CO) assay. We found that the CO-staining intensities in the IO of Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice were increased as compared with those of Itpr1<sup>flox/flox</sup> mice (Figure 7A). Relative CO activity. Principal nuclei (IOPR), Itpr1<sup>flox/flox</sup>: 0.97 ± 0.03, Wnt1-Cre;Itpr1<sup>flox/flox</sup>: 1.17 ± 0.05, P < 0.05; medial inferior olive (IOM), Itpr1<sup>flox/flox</sup>: 0.68 ± 0.02, Wnt1-Cre;Itpr1<sup>flox/flox</sup>: 1.64 ± 0.1, P < 0.0001; and dorsal accessory inferior olive (IOd), Itpr1<sup>flox/flox</sup>: 0.64 ± 0.02, Wnt1-Cre;Itpr1<sup>flox/flox</sup>: 0.95 ± 0.06, Means ± sem, Student’s t-test P < 0.01, n = 6 from 3 mice). Inferior olive IP3R1 expression was below the threshold of immunohistochemical detection even in wild-type mice, most likely because of its significantly lower expression relative to hippocampal, striatal, and cortical neurons. In contrast, we did not detect a significant difference in the CO staining intensities of the BG between Wnt1-Cre;Itpr1<sup>flox/flox</sup> and Itpr1<sup>flox/flox</sup> mice (Relative CO

**FIGURE 4** | Correlation of abnormal PC firing with the expression of Dystonia in freely moving Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice. (A) Representative recording of PC spiking in freely moving Itpr1<sup>flox/flox</sup> and Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice. Distinct involuntary movements of Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice were highly correlated with change in multi-unit activities of PCs. Bottom picture, representative dyskinetic postures during underlined PC firing periods. Blue line: extension; orange line: compression with rigidity. Dots represent CSs. (B) PC spike patterns in wild-type mice before (upper panel) and after (lower panel) intraperitoneal harmaline injection. Dots represent CSs. (C) Frequency of CSs in anesthetized (upper panel) and behaving (lower panel) Itpr1<sup>flox/flox</sup> and Wnt1-Cre;Itpr1<sup>flox/flox</sup> mice. Anesthetized mice, Itpr1<sup>flox/flox</sup>: 1.41 ± 0.27 count/s (Mean ± sem. 21 recording sites from 5 animals); Wnt1-Cre;Itpr1<sup>flox/flox</sup>: 2.24 ± 0.33 count/s (22 recording sites from 4 animals), P = 0.053, Mann-Whitney U-test. Behaving mice, Itpr1<sup>flox/flox</sup>: 1.61 ± 0.23 (10 recording sites from 4 animals); Wnt1-Cre;Itpr1<sup>flox/flox</sup>: 14.96 ± 1.64 (12 recordings from 4 animals), P < 0.0001, Mann-Whitney U-test. (D) Relationship between firing rate and two postures. Blue arrowhead: extension; orange: shrinkage with rigidity. (E) Population firing data. (N = 4 mice, n = 20 recording sites, paired Student's t-test ***P < 0.0001).
activity. $I_{\text{Pr1}}^{\text{flx/flx}}$, 1.02 ± 0.02; Wnt1-Cre;$I_{\text{Pr1}}^{\text{flx/flx}}$, 0.98 ± 0.03; Student’s t-test $P = 0.20$, $n = 6$ from 3 mice) (Figure 7B).

In addition, contrary to the PC activity patterns, we did not observe distinct correlations between BG spiking activity and dystonic movements and activity patterns were essentially indistinguishable (Figure 7C). Activity levels of neurons in the Wnt1-Cre;$I_{\text{Pr1}}^{\text{flx/flx}}$ BG were also similar to those of $I_{\text{Pr1}}^{\text{flx/flx}}$ BG (firing rate of the BG neurons, single-unit activity $I_{\text{Pr1}}^{\text{flx/flx}}$: 8.523 ± 1.669 ($n = 20$). Wnt1-Cre;$I_{\text{Pr1}}^{\text{flx/flx}}$: 15.05 ± 4.398 ($n = 22$). Mean ± sem. Student’s t-test $P = 0.19$). In addition, the expression levels of $c_fos$ mRNA and cFos in the striatum were comparable between $I_{\text{Pr1}}^{\text{flx/flx}}$ and Wnt1-Cre;$I_{\text{Pr1}}^{\text{flx/flx}}$ mice (Figures 7D,E).

To examine whether altered IO activity was associated with dystonia in the Wnt1-Cre;$I_{\text{Pr1}}^{\text{flx/flx}}$ mice, we pharmacologically inhibited IO activities. We found that lidocaine injection into IO decreased opisthotonus of Wnt1-Cre;$I_{\text{Pr1}}^{\text{flx/flx}}$ mice (Figure 7F), although tremor of limbs and ataxia were still observed (Movie S4). In contrast, pharmacological inhibition of bilateral BG (entopeduncular nucleus) activity by lidocaine injection did not significantly affect frequency of opisthotonus in Wnt1-Cre;$I_{\text{Pr1}}^{\text{flx/flx}}$ mice (Figure 7G; Movie S5). These results suggested that altered activities of olivocerebellar tracts cause dystonia in Wnt1-Cre;$I_{\text{Pr1}}^{\text{flx/flx}}$ mice in a BG-independent manner.

**DISCUSSION**

In this study, we demonstrated that genetic deletion of IP3R1 within cerebellum and brainstem is sufficient to cause dystonia in mice, and that further pharmacological inactivation of the cerebellum or the IO and deletion of PCs ameliorate the dyskinesia. Thus, our data suggested that dystonia is a gain of function rather than loss of function of olivocerebellar pathways, which is in line with the previous findings (Campbell et al., 1999; Pizoli et al., 2002). Moreover, using electrophysiological recordings of PC activity from freely behaving dystonic mice, we have also demonstrated the relationship between temporal changes of PC spike activity possibly triggered by altered IO activation and the expression of dystonia. Although altered PC activity was found in the movement-restricted dystonic rat (Ledoux and Lorden, 2002), how the temporal changes of PC firing patterns are related to ongoing dystonic movements were unknown. We revealed a distinct pattern of PC firing in freely moving Wnt1-Cre;$I_{\text{Pr1}}^{\text{flx/flx}}$ mice during distinct dystonic postures, which could not be observed in neither the anesthetized preparation nor the cerebellar slices. During dystonic movements, PC activities exhibiting repetitive CS patterns were predominant. Since CSs are thought to be important for voluntary movements (Welsh et al., 1995; Kitazawa et al., 1998; Welsh, 2002), the repetitive abnormal synchronized CSs with high frequency during rigid posture may in part underlie dystonia.

Chen et al. recently reported the low-frequency oscillations of flavoprotein autofluorescence in the cerebellar cortex of rotterting mice (Chen et al., 2009), and showed that the oscillation was accentuated during dystonia. However, the cellular types and mechanisms that contribute to the enhancement of the oscillation in the mutant mice were unknown. By measuring the PC activities from behaving Wnt1-Cre;$I_{\text{Pr1}}^{\text{flx/flx}}$ mice, here we found a precise temporal association between CS-dominant PC firings and distinct dystonic movements. Thus, increase of CF frequency through IO activation may underlie the expression of dystonia in Wnt1-Cre;$I_{\text{Pr1}}^{\text{flx/flx}}$ mice. This hypothesis is in line with our finding that infusion of AMPAR blocker in the cerebellum ameliorates dystonia in Wnt1-Cre;$I_{\text{Pr1}}^{\text{flx/flx}}$ mice, because AMPA receptor blocker inhibits CF-PC synapse transmission. Although we don’t know the relationship between the CS-dominant PC firings in the present study and the low-frequency oscillations in cerebellar cortex shown in the Chen’s paper, the CS-dominant PC firings is most likely to be independent of the cerebellar

oscillation, since the oscillation was reported to be intrinsic to the cerebellar cortex and the cerebellar blockade by AMPA receptor or by electrical stimulation of PFs did not affect the oscillation (Chen et al., 2009).

Our results also suggest a previously unknown pathogenesis of dystonia induced by abnormal cerebellar activity in mice, namely BG-independent dystonia, based on the following facts; no apparent motor abnormality of BG-specific IP3R1 conditional mice, no difference in CO staining intensity in Itpr1flox/flox and Wnt1-Cre;Itpr1flox/flox mouse’s BG, little correlations of BG activity and dystonic movement, and the ineffectiveness of pharmaceutical BG inactivation on dystonia of Wnt1-Cre;Itpr1flox/flox mice. Thus, we propose that altered cerebellar activity causes dystonia by a mechanism, which does not involve BG activity in Wnt1-Cre;Itpr1flox/flox mice. It is possible that the abnormal cerebellar outputs generated by IO might be directly sent to spinal cords via red nucleus or reticular formation. It is also worth mentioning that the distinctive CSs appeared only in awake Wnt1-Cre;Itpr1flox/flox mice, and that altered activation of IO itself was not sufficient for generation of dystonia, since harmaline, which evokes similar CS dominant spike patterns of PCs, does not cause dystonia. Therefore, uncoordinated timings between voluntary corticospinal signals and the involuntary cerebellar-reticulospinal signals generated by IO activation with spinocerebellar (somatosensory) inputs may cause simultaneous activation of agonist- and antagonist muscles, leading to dystonia in the Wnt1-Cre;Itpr1flox/flox mice.

In sum, our study suggests that BG-independent dystonia is triggered by abnormal cerebellar outputs in mice. Wnt1-Cre;Itpr1flox/flox mice may provide a therapeutic dystonia model solely dependent upon abnormal neural activities within the cerebellum and brainstem. Recently, it was reported that a deletion
of the Itpr1 gene is associated with involuntary movements in patients of spinocerebellar ataxia type 15 (Di Gregorio et al., 2010; Marelli et al., 2011), which has been thought to be pure cerebellar ataxia (Hara et al., 2008). The above involuntary movements may be dystonia-related, given that dystonia can be a prominent symptom in SCAs, including some cases with exclusively cerebellar pathology (Manto, 2005). However, since spinocerebellar ataxia type 15 is a slow progressive autosomal dominant disease exhibiting cerebellar atrophy with PC death (Knight et al., 2003; Gardner et al., 2005), severe dystonia would not happen in human. Nevertheless, IP3R is known to interact with Na-K ATPase, a causal gene for DYT12 dystonia, and a Na-K ATPase inhibitor, ouabain, causes aberrant Ca2+ release from the IP3R (Zhang et al., 2006). Thus, it is possible that dysfunction of IP3R1 could be associated with dystonia in human. Further studies on the mechanism by which disturbed Ca2+ signals from IP3R1 lead to the repetitive synchronized CSs in our mutant mice, such as potential Ca2+-dependent regulation of gap junction among IO neurons, may contribute to the understanding of pathogenesis and the development of new therapies for dystonia.
