ABSTRACT

SET domain bifurcated protein 1 (SETDB1) is a human histone-lysine methyltransferase, which is amplified in human cancers and was shown to be crucial in the growth of non-small and small cell lung carcinoma. In addition to its catalytic domain, SETDB1 harbors a unique tandem tudor domain which recognizes histone sequences containing both methylated and acetylated lysines,
and likely contributes to its localization on chromatin. Using X-ray crystallography and NMR spectroscopy fragment screening approaches, we have identified the first small molecule fragment hits that bind to histone peptide binding groove of the TTD of SETDB1. Herein, we describe the binding modes of these fragments and analogues and the biophysical characterization of key compounds. These confirmed small molecule fragments will inform the development of potent antagonists of SETDB1 interaction with histones.

INTRODUCTION

Post-translational modifications (PTMs) such as methylation, phosphorylation, acetylation, ubiquitination, and SUMOylation of histone proteins impact gene expression by altering chromatin compaction or recruiting effector proteins.\(^1\)\(^-\)\(^3\) Methylation of histones occurs predominantly at the lysine and arginine sidechains of histone 3 (H3K4, H3K9, H3K27, H3K36, H3K79 and H3K2) and histone 4 (H4K20 and H4R3). Unlike some other PTMs, methylation of a lysine or arginine sidechain does not change overall charge but results in subtle alterations in size and hydrophobicity, which can influence chromatin packing.\(^4\) Transcriptional activation or repression is dependent on the position and degree of methylation\(^5\) and aberrant methylation of histones can result in dysregulation of cell growth and development of cancer.\(^6\) Many of the histone methyl transferases have been extensively studied and selective inhibitors have been effective in preclinical models.\(^7\)\(^-\)\(^9\)

Human SETDB1 is a histone-lysine methyltransferase (HMT), which specifically trimethylates histone H3 lysine 9 (H3K9me3). It is therefore deemed central in the silencing of specific euchromatic genes.\(^10\) Recent studies have also suggested that SETDB1 could be an oncogene. Its overexpression is crucial to the growth of non-small and small cell lung cancer cell lines and has
been reported in various human cancers.\textsuperscript{11-13} Overexpressed SETDB1 increases H3K9me3 leading to alterations in gene expression.\textsuperscript{14}

SETDB1 contains a tandem tudor domain (TTD), a methyl-DNA binding domain (MBD), and a SET domain.\textsuperscript{15} The MBD of SETDB1 promotes direct binding to methylated DNA sites and mediates trimethylation of H3K9 in a site-directed fashion. The SET domain catalytically “writes” the epigenetic methyl mark, which then goes on to recruit proteins belonging to the Heterochromatin Protein 1 (HP1) family to control gene repression.\textsuperscript{10} Tudor domains are associated with the recognition of different methylation levels of lysine and arginine residues and the TTD of SETDB1 has been associated with the recognition of di- and trimethylation states of H3K9.\textsuperscript{16,17} To the best of our knowledge, and despite the evident therapeutic importance of SETDB1, no antagonists of this protein have been reported to date. We therefore undertook fragment based approach toward discovery of ligands for SETDB1. We successfully crystallized the truncated tandem tudor domain of SETDB1 in complex with a histone 3 peptide dimethylated at lysine 9 and acetylated at lysine 14 (H3K9me2K14ac).\textsuperscript{18} The co-crystal structure shows that H3K9me2K14ac interacts with the protein at two interconnected pockets within the TTD: a small pocket where the methyl lysine (Kme) binds (hereafter called the Kme binding pocket) and a relatively larger and deeper pocket engaged by the acetyl lysine (the Kac pocket) (Figure 1).
Figure 1. Crystal structure of SETDB1-TTD in complex with H3K9me2K14ac peptide (PDB: 6BHD).

We used a crystal soaking fragment screening approach to identify small-molecule ligands occupying the Kme and/or Kac pockets of SETDB1-TTD. Crystal structures revealed binding modes that could enable structure-guided hit optimization toward the development of SETDB1 antagonists.

RESULTS AND DISCUSSIONS

Hit Identification. In order to identify small molecule antagonists of SETDB1-TTD, we screened a fragment library of 252 compounds by soaking the apo crystals of SETDB1-TTD with pools of 3 compounds and identified a single fragment hit (1). Co-crystal structure of 1 with SETDB1-TTD
revealed that it binds in the Kme pocket (Figure 2). However, fragment 1 did not show any HSQC shift at concentrations as high as 10 mM, indicating very weak binding.

As a major part of the H3K9me2K14ac peptide occupies and forms hydrogen bonding interactions in and around the Kac pocket, fragments binding in the Kac pocket are likely to have higher ligand efficiency and can potentially be optimized to improve affinity. To test this hypothesis, we selected and soaked 5 constrained analogues of known bromodomain inhibitors synthesized in our laboratory (Supplementary Figure 1). Bromodomain inhibitors are known acetyl lysine mimics and could potentially bind to the Kac pocket of the SETDB1-TTD. Out of 5 fragments, one fragment (2) was found to bind to SETDB1-TTD occupying the TTD Kac pocket (Figure 2). Binding of 2 to SETDB1-TTD was also confirmed by HSQC NMR at 5mM (Supplementary Figure 2). In order to explore the SAR of these hits and assess the feasibility of improving their activity, a small set of analogs was synthesized and tested by HSQC NMR and/or by SPR.
Figure 2. Superimposed crystal structures of the SETDB1 TTD in complex with 1 (PDB ID: 5KE2) and 2 (PDB ID: 6AU2) occupying the Kme and Kac pockets, respectively.

Chemistry

The tricyclic triazole 2 was prepared from commercially available 2-aminobenzyl alcohol (11), which was reacted with ethylchloroacetate (12) in the presence of sodium hydride to give the lactam. Treatment of the lactam with Lawesson’s reagent led to the corresponding thioamide 13, which was subsequently condensed with acethydrazide (14) to give the desired tricycle 2 in 6% yield overall yield (Scheme 1).

Scheme 1a
N-Derivatized tricycle 4 was synthesized by the route outlined in Scheme 2. Diamine 15 was refluxed with ethylchloroacetate in toluene in the presence of triethylamine to obtain 16 as the major product. The crude product was selectively Boc-protected at the secondary amine to furnish 17. The resulting material was carried directly through to intramolecular cyclization mediated by potassium tert-butoxide to give the lactam 18 in 35% isolated yield over three steps after recrystallization. Treatment of the cyclic amide with Lawesson’s reagent yielded thioamide 19, which was then refluxed with acethydrazide for three days to furnish the triazole 20 in 80% yield after recrystallization. Finally, the Boc group was deprotected under acidic conditions and the resulting secondary amine was capped with acetyl chloride to give compound 4.

Scheme 2a

Reagents and conditions: (a) (1) NaH, Toluene, 80 °C; (2) Lawesson’s reagent, THF, 60 °C (b) nBuOH, 100 °C, 6% overall yield.

Reagents and conditions: (a) ethylchloroacetate, TEA, Toluene, 100 °C (b) Boc2O, cat.DMAP, THF, rt (c) KO'Bu, THF, 0 °C, 35% over 3 steps (d) Lawesson’s reagent, THF, 60 °C, 53% (e) acethyldrazide, n-BuOH, 100 °C, 80% (f) 1.25 M HCl in MeOH, 50 °C, 97% (g) AcCl, TEA, DMF, rt, 54%
Triazoles 5-8 were prepared according to Scheme 3. Diamine 15 was treated with Boc anhydride followed by acetic anhydride to give the Boc-protected acetamide 25, which was treated with Lawesson’s reagent to furnish thioamide 26. Triazole 27 was obtained in moderate yield by treating 26 with acethydrazide under microwave irradiation. Deprotection of the Boc group was accomplished with hydrochloric acid in methanol and the free amine was treated with acetic anhydride or with methanesulfonyl chloride in the presence of base to yield the corresponding acetamide 5 and sulfonamide 7, respectively. After the deprotection of triazole 27 under the same conditions, the free amine of the crude product was treated with triphosgene followed by methylamine to give 6. The corresponding triazole carboxylic acid 8 was prepared by reacting 28 with acethydrazide.

Scheme 3a
aReagents and conditions: (a) Boc2O, TEA, THF, rt, 99%; (b) Ac2O, DCM, rt, 89%; (c) Lawesson’s reagent, THF, 60 °C, 64%; (d) acethydrazide, n-BuOH, 100 °C, 47%; (e) (1) 1.25 M HCl in MeOH, 50 °C, 65%; (2) triphosgene, TEA, DCM, rt; (f) (1) 1.25 M HCl in MeOH, 50 °C; (2) Methane sulfonyl chloride, TEA, MeCN, rt (g) (1) 1.25 M HCl in MeOH, 50 °C; (2) Methane sulfonyl chloride, TEA, MeCN, rt (h) acethydrazide, EtOH, reflux, 35%

*para*-Substituted triazole analogues 9a-e were synthesized from intermediate 25 (Scheme 4). Halogenation of 25 with NBS and NCS gave 29a and 29b, respectively. Following the same protocol for converting 25 into 5 (Scheme 4), the corresponding halogenated intermediates 29a and 29b were converted to 9a and 9b. Palladium-catalyzed cyanation of 9a gave 9c, and Suzuki coupling of 9a with the corresponding boronic acids gave 9d and 9e.

Scheme 4a
Synthesis of the triazole fragment-linked molecule 10 began by condensing intermediate 28 with intermediate 32 to give the corresponding triazole carboxylic acid 33. The alcohol 34, which was obtained by the reduction of the carboxylic acid 33, was converted into the corresponding phthalimide 35 under Mitsunobu conditions. Treatment of 35 with hydrazine to remove the phthalimide group followed by acetylation and deprotection of the Boc group gave intermediate 37.

Scheme 5\textsuperscript{a}
Reagents and conditions: (a) EtOH, reflux, 57% (b) LAH, THF, 54% (c) DIAD, PPh₃, phthalimide, THF, rt, 96% (d) (1) hydrazine, MeOH, reflux; (2) N-acetyl-N-methoxyacetamide, MeOH, rt, 51% (e) TFA, 67%

The peptide intermediate 40 for the synthesis of 10 was synthesized from peptide 38, which was in turn obtained using a standard 2-chlorotrityl resin protocol. Hydrogenolysis of the Cbz group of 38 followed by dimethylation via reductive amination of the lysine side chain with formaldehyde gave peptide 40 in 85% yield over two steps (Scheme 6). Coupling of the acid 40 with the amine 37 was followed by deprotection of Boc and tBu groups with TFA to give 10 (Scheme 7).

Scheme 6

**Biochemical evaluation and SAR of the fragments occupying Kme pocket.** In the co-crystal structure of the fragment hit 1 with SETDB1-TTD, the phenyl ring of the tetrahydroisoquinoline core occupies the aromatic cage formed by W358, W363 and F379 and the carbonyl group makes hydrogen bonding with D382 (Figure 3a). However, 1 did not show any significant shift in the HSQC NMR of SETDB1-TTD at concentrations up to 10 mM, indicating that 1 interacts very weakly with the Kme pocket. Superimposed structures of SETDB1-TTD in complex with 1 and H3K9me2K14ac within the binding pocket (Figure 3b) indicate that the fragment could be grown towards the Kac pocket, which could potentially pick up additional interactions with the protein and thus improve affinity. We purchased a library of 19 amides (Supplementary figure 3) and synthesized 3 amides, extending fragment 1 in the desired direction. Ligand-protein interactions were assessed using HSQC NMR as a first pass screen. None of the 22 analogs tested showed HSQC NMR shift at 10 mM. However, we were able to obtain the co-crystal structure of 3 with SETDB1-TTD, wherein the tetrahydroisoquinoline core of 3 occupies the aromatic cage of the Kme pocket, and the amide extends towards the Kac pocket (Figure 3c). No electron density was observed for the furan group, indicating suboptimal interactions with the protein. As none of the analogs of 1 showed any significant activity, we turned our focus toward identifying fragments that occupy the Kac pocket.
**Figure 3.** Crystal structure of SETDB1 TTD in complex with fragments. (a) Binding mode of 1 in the aromatic cage of Kme pocket. (b) Superimposed structures of 1 (grey) (PDB: 5KE2) with the co-crystal structure of H3K9me2K14ac (orange) (PDB: 6BHD). (c) Binding mode of 3 in the aromatic cage of the Kme pocket (PDB ID: 5KE3). (d) Chemical Structure of 3.

**Biochemical evaluation and SAR of fragments occupying the Kac pocket.** In the co-crystal structure of SETDB1-TTD in complex with 2, the triazole ring of 2 participates in π-stacking interactions with F332 and its phenyl ring is buried in the narrow pocket, forming hydrophobic interactions with I333, G300, F296, and C329. Both the nitrogen atom in the triazole ring and the oxygen atom in the seven membered ring form hydrogen bonds with two water molecules (Figure 4a). At 10 mM, 2 showed a significant HSQC NMR shift. Similarly, the simple
acetamide derivative 4 showed a significant HSQC NMR shift (Supplementary Figure 2), but neither compound showed significant binding by ITC (not shown). In the H3K9me2K14ac co-crystal structure, the acetyl group of K14ac forms hydrogen bonding interactions with G300 and Y389, both of which are found in the vicinity of 2. We therefore synthesized the corresponding open chain analogue 5 and obtained a co-crystal structure. As expected, the N-acetyl group of 5 formed hydrogen bonds with G300 and Y389 (Figure 4b). A slight shift in the scaffold binding pose compared with 2 produced an additional hydrogen bond between the trizole ring of 5 and the side-chain of R394, but this also leads to reduced interactions at the I333 hydrophobic cavity and loss of π-stacking with F332 (Figure 4c). Compound 5 showed a strong HSQC NMR shift at 5 mM (Supplementary Figure 2) and displayed Kd values in low millimolar ranges by ITC (Kd=3.5 mM) (Figure 4d) and SPR (Kd=3.5 mM) (Supplementary Figure 4).
Compound 5
Kd = 3.5 mM
Figure 4. (a) Binding mode of 2 in the Kac pocket. (b) Binding mode of 5 in the Kac pocket (PDB ID: 6AU3). (c) Superimposed structures of 2 (yellow) with 5 (grey) (d) ITC data of 5. (e) Chemical Structures of 2, 4 and 5.

We also synthesized the corresponding urea 6, sulfonamide 7, and carboxylic acid 8 (Figure 5). All three compounds were predicted to form additional or alternate hydrogen bonds with the protein, however, only the sulfonamide analog 7 showed a strong HSQC NMR shift at 5 mM (Supplementary Figure 2) and affinity comparable to 5 by ITC (Figure 5) and SPR. (Supplementary Figure 4) (Kd = 4mM – 17mM in both assays).
Figure 5. (a) Chemical Structures of 6-8. (b) ITC data of 7.

Despite forming a number of hydrogen bonding interactions with the protein, 5 showed only weak binding by ITC and SPR, which is likely due to incomplete occupation of the large pocket that is occupied by the native peptide H3K9me2K14ac. We therefore decided to grow the fragment 5 into the pocket occupied by the peptide. We initially focused on simple substitutions at the para position of the phenyl ring of 5 to rescue hydrophobic interactions observed between 2 and I333. However, none of the para-substituted analogues showed significant improvement of binding compared to 5 as measured by SPR (Table 1 and Supplementary Figure 4).

Table 1. SPR data of substituted analogues of 5. Binding of compounds 5, 9a, 9b, 9c and 9d to SETDB1 TTD was confirmed by SPR with $K_d$ values mostly in single digit milimolar.
Next, we linked fragment 5 with a portion of the H3K9me2K14ac peptide that occupies the desired Kme pocket and linker region to obtain compound 10. The co-crystal structure indicates that 10 recapitulated the binding pose of 5 in the Kac pocket and the binding pose of H3K9me2K14ac in the Kme pocket and linker (Figure 6). Compound 10 showed a significant HSQC NMR shift, however displayed weak binding by SPR (SPR Kd = 1.27 mM), despite occupying and making interactions in the major part of the pocket occupied by the native peptide. This may be because the interactions in the cavities occupied by the native peptide, but not occupied by 10, may be important for potency. This weak activity may reflect conformational strain associated with binding of the chemical series explored here. Structural dynamics of the TTD may also impact accessibility of the binding pocket.
Figure 6. (a) Binding mode of 10 (PDB ID: 6BPI) (b) Overlay of the structures of 10 (green), 5 (purple) with the H3K9me2K14ac peptide (orange). (c) Chemical structure of 10.

Conclusion

We have identified the first fragment hits occupying the peptide binding pocket of SETDB1 TTD, which demonstrates its ligandability. Fragments occupying the Kac pocket form interactions with the protein. The most promising binding interactions were observed in compound 5, which included four hydrogen bonds and multiple hydrophobic interactions, however showed only weak binding by ITC and SPR. Compound 10, a hybrid of fragment 5 and a histone peptide capable of spanning both Kme and Kac pockets, did not show significant
binding, suggesting that cavities occupied by A15-R17 of the native peptide may be important for potency. Future compounds exploiting this portion of the binding site will help further define the structural chemistry of the SETDB1 TTD and map the road towards potent and selective SETDB1 chemical probes.

**EXPERIMENTAL SECTION**

**Protein expression and purification.** The expression construct for N-terminal His6-tagged SETDB1 Tudor domain (residues 197 – 403) subcloned into pET28a-MHL vector was transformed into BL21(DE3)-pRARE2 cells. The cultures were grown in Terrific Broth medium (TB) in the presence of 50 µg/mL kanamycin and 34 µg/mL chloramphenicol at 37 °C. For NMR analyses, the cultures were grown in auto-induction M9 minimal medium containing 1.2 g/l 15N-ammonium chloride (Sigma 299251) as the sole nitrogen source using an auto-induction method. For SPR experiments, the expression construct was N-terminally biotinylated SETDB1 Tudor domain (residues 197 – 403) subcloned into pET28BIOH_LIC vector and growth was done as usual but supplemented with 1 mg/ml of biotin. The overexpression of SETDB1 Tudor was induced by addition of isopropyl-1-thio-D-galactopyranoside (IPTG), final concentration 0.5 mM, and incubated overnight at 16 °C. Next day, the cells were harvested by centrifugation at 12,227 × g (10 min, 4 °C). Details of the purification procedures are provided in the supporting information.

**Protein crystallization.** Purified SETDB1 was crystallized using hanging drop vapor diffusion method at 20 °C by mixing 1.5 µl of the protein solution at 5 mg/ml with 1.5 µl of the reservoir solution containing 25% PEG3350, 0.2 M LiSO4, 0.1 M Bis-Tris, pH 6.5. Matured SETDB1 crystals were transferred to the soaking solution containing 27% PEG3350, 0.2 M LiSO4, 0.1 M
Bis-Tris, pH 6.5, 50 mM of the ligand and 0.5% DMSO. Soaking time varied from 24 to 48 hours.

**Biophysical assays.** Isothermal titration calorimetry (ITC) for 5 was performed at 25 °C using Nano ITC instrument (TA Instruments, USA). The cell was loaded with 80 µM SETDB1 (Tudor domain) in 20 mM HEPES pH 7.5 and 250 mM NaCl. The syringe was loaded with 100 mM compound 5 dissolved in the same buffer (pH was checked and no DMSO was used). 25 injections of 2 µL volumes were applied at 180 s intervals. “Nano Analyze” software package (supplied by the manufacturer) was used for data analysis. The data was fit to a one binding site model.

ITC for compound 7 was performed using the same instrument and using similar conditions as for compound 5. The cell was loaded with 98 µM SETDB1 in 20 mM HEPES pH 7.5 and 250 mM NaCl. The syringe was loaded with 50 mM compound 7 (It was not possible to prepare 100 mM solution due to limited solubility) dissolved in the same buffer as protein (again pH was checked and no DMSO was used).

NMR spectroscopy. 1H-15N HSQC-TROSY spectra were collected at 298 K on 500 MHz Bruker Avance spectrometer equipped with 1.7 mm micro cryoprobe. Experiments were performed at 5 mM ligand concentrations with 190 µM 15N labeled SETDB1 in 20 mM HEPES pH 7.5 and 250 mM NaCl, 2.5% DMSO, and 10% D2O. Negative controls contained 2.5% DMSO and no compound.

**General Chemistry.** All solvents acetonitrile, dimethylformamide (DMF), tetrahydrofuran (THF), dichloromethane (DCM), and trifluoroacetic acid (TFA) were of reagent grade quality, purchased from commercial sources and used as received. Flash column chromatography was
carried out using Silicycle 230-400 mesh silica gel. Thin-layer chromatography (TLC) was performed on Macherey Nagel precoated glass-backed TLC plates (SIL G/UV254, 0.25 mm) and visualized using a UV lamp (254 nm) followed by KMnO₄, ninhydrin or iodine stain. Reported Rₛ values are dependent on ambient humidity. NMR spectra were recorded at 25 °C on Bruker Advance III 400 MHz spectrometer, Varian Mercury 400, Agilent DD2 500, or Agilent DD2 600 instrument. Recorded shifts for protons are reported in parts per million (δ scale) downfield from tetramethylsilane and are referenced to residual protons in the NMR solvents (CDCl₃: 7.26 or CD₃CN: δ 1.94, centre line). Chemical shifts for carbon resonances are reported in parts per million (δ scale) downfield from tetramethylsilane and are referenced to the carbon resonances of the solvent (CDCl₃: δ 77.16 or CD₃CN: δ 1.32, centre line). Data are represented as follows: chemical shift δ in ppm, multiplicity (s singlet, d doublet, t triplet, q quartet, m multiplet, br broad), coupling constant J in Hz and integration. High resolution mass spectra were obtained on a VG 70-250S (double focusing) mass spectrometer at 70 eV or on an ABI/Sciex Qstar mass spectrometer with ESI source, MS/MS and accurate mass capabilities or on JEOL AccuTOF-DART instrument.

All the test compounds synthesized showed ≥95% pure as determined by HPLC/MS. Low-resolution mass spectra (ESI) were collected on an Agilent Technologies 1200 series HPLC paired to a 6130 Mass Spectrometer. Compounds were resolved on Phenomenex’s Kinetex 2.6u C18 50x4.6mm column at room temperature with a flow of 1 mL/min. The gradient consisted of eluents A (0.1% formic acid in double distilled water) and B (0.1% formic acid in HPLC-grade acetonitrile). Method A: A linear gradient starting from 5% of B to 95% over 15 min at a flow rate of 1.0 mL/min. Method B: A linear gradient starting from 5% of B to 95% over 4.00 min at a flow rate of 1.0 mL/min. Stays constant at 95% for 1 min and then returns to 5% over 0.5 min. Method C: Stays constant at 5% of B for 1.00 min at a flow rate of 1.0 mL/min, followed by a linear
gradient to 95% over 8.0 min. Stays constant at 95% of B for 1.00 min and then returns to 5% B over 1.00 min. Compound 2 (Method A); Compounds 4, 9c, 9d (Method B); Compounds 6-8, 9a, 9b, 9e (Method C).

**Synthetic procedures.** General procedure A: synthesis of thioamides. Amide (1 equiv) was dissolved in THF (0.1 M) and Lawesson’s reagent (0.6 – 0.75 equiv) was added. The reaction was heated to 60 ºC for 2 – 4 hours until complete by TLC analysis. Excess silica gel was added to the stirred solution and was allowed to cool to room temperature while stirring. The solvent was evaporated in vacuo and the product dry loaded onto silica gel. The silica-loaded crude product was loaded onto a silica column and the product carefully eluted (0% to 30% EtOAc in hexanes ) as a yellow band following the initial dark byproduct band.

General procedure B: Boc deprotection and acetylation of amines. The Boc-protected amine (1 equiv) was dissolved in 1.25 M HCl in methanol (15 equiv) and the solution was heated to 50 ºC overnight. The reaction achieved full conversion as gauged by LC/MS analysis and the solvent was evaporated under reduced pressure. The residue was dissolved in acetonitrile (0.2 M) and Amberlite IRA-67 was added to free-base the amine followed by addition of acetic anhydride (1.5 equiv). The reaction was allowed to stir for 6 – 12 hours and after removal of the solvent, crude products were purified by reverse phase or normal phase column chromatography.

General procedure C: Synthesis of triazoles from thioamides. Thioamide (1 equiv) was added to a microwave vial followed by acethyldrazide or formic hydrazide (4 – 5 equiv). n-Butanol (0.5 M) was added and the vial capped and heated at 100 ºC under normal microwave irradiation for 24 – 36 hours until the starting material was consumed as gauged by LC/MS analysis. The solvent was evaporated in vacuo and the hydrazide sublimed from the reaction mixture under high vacuum.
at 100 ºC. The crude product was subsequently purified by reverse phase column chromatography or by recrystallization.

General procedure D: Synthesis of para-halogenated N-acylanilines. N-acylaniline (1 equiv), NBS/NCS (2 equiv) and triphenylphosphine sulfide (0.1 equiv) were dissolved in chloroform (0.05 M) and stirred for 1 (NBS) to 2 (NCS) days until the starting material was fully consumed. The solvent was evaporated in vacuo and the crude product was redissolved in EtOAc, washed subsequently with water, saturated sodium thiosulfate, water and brine and dried over sodium sulfate. The crude product was then purified by column chromatography.

1-methyl-4H,6H-benzo[e][1,2,4]triazolo[3,4-c][1,4]oxazepine (2). 2-aminobenzylalcohol (11) (500 mg, 4.06 mmol) was combined with sodium hydride (195 mg, 4.87 mmol) in toluene (8.1 mL) and added with ethylchloroacetate (12) (0.435 mL, 4.06 mmol). The solution was heated to 80 ºC for 1 hour, cooled to room temperature, diluted with EtOAc and worked up with 10% aqueous HCl. The organic layer was washed with water, brine, and dried over sodium sulfate. After passing through silica column the crude lactam (74.2 mg, ~11%, pale yellow solid (Rf(1:1 EtOAc:hexanes): 0.33) was carried through to the next step. Crude lactam (73.7 mg, 0.45 mmol) was dissolved in toluene (4.52 mL) and Lawesson’s reagent (183.1 mg, 0.45 mmol) was added. The solution was heated to 60 ºC for 5 hours, concentrated and passed through a silica gel plug (Rf (2:5 EtOAc:hexanes): 0.64). The crude thioamide product 13 (0.092 g, 0.52 mmol) was mixed in n-butanol (2.2 mL) and acethydrazide (14) (76.3 mg, 1.03 mmol) was added. The solution was heated to 120 ºC for four days, the solvent removed in vacuo and the crude product was purified by column chromatography. Yield: 48.0 mg, 53%, pale yellow crystals. Rf (1:19 MeOH:EA): 0.1.

$^1$H NMR (500 MHz, CDCl$_3$) $\delta$ 7.60 (d, $J = 7.9$, 7.4, 1.7 Hz, 1H), 7.55 (ddd, $J = 7.6$, 1.8, 0.5 Hz, 1H), 7.49 (dt, $J = 7.5$, 1.2 Hz, 1H), 7.39 (dd, $J = 8.0$, 0.9 Hz, 1H), 4.66 (s, 2H), 4.46 (s, 2H), 2.62
(s, 3H). $^{13}$C NMR (126 MHz, CDCl$_3$) $\delta$ 151.8, 150.9, 134.4, 131.9, 131.1, 130.4, 129.3, 122.6, 67.1, 59.2, 11.9. *tert*-butyl 2-oxo-1,2,3,5-tetrahydro-4H-benzo[e][1,4]diazepine-4-carboxylate (18). In a flame dried round-bottom flask, 2-aminobenzylamine (10 g, 82 mmol) was dissolved in toluene (410 mL, 0.2 M). Triethylamine (12.6 mL, 90 mmol) and ethylchloroacetate (9.2 mL, 86 mmol) were added and the solution was stirred under reflux at 110 °C for 22 hours, until complete as indicated by TLC and LC/MS. The reaction mixture was cooled to room temperature and water (410 mL) was added. The organic layer was separated and washed with water, followed by brine, dried over sodium sulfate and concentrated to yield ethyl (2-aminobenzyl)glycinate (16) which was used in the subsequent step without further purification. Yield: 15.8 g, 93%, brown/orange oil. $R_f$ (EtOAc): 0.51. $^1$H NMR (300 MHz, CDCl$_3$) $\delta$ 7.27 – 7.15 (m, 1H), 7.13 – 7.07 (m, 1H), 7.06 – 7.00 (m, 1H), 6.69 – 6.67 (m, 1H), 4.24 – 4.17 (m, 2H), 3.79 (s, 2H), 3.40 (s, 2H), 1.31 – 1.27 (m, 3H). $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 172.7, 146.9, 130.3, 128.7, 123.2, 117.8, 115.8, 60.9, 52.1, 49.8, 14.3. IR (neat) $\tilde{\nu}$ (cm$^{-1}$): 3436, 3342, 2976, 1730, 1617, 1495, 1459, 1192, 1131, 749. The crude product 16 (15.8 g, 75.9 mmol) was dissolved in THF (760 mL) followed by the addition of Boc$_2$O (21.8 mL, 94.8 mmol) and a catalytic amount of DMAP. The solution was allowed to stir for 20 hours until reaction was complete by TLC analysis. The THF was removed under reduced pressure, and the residue redissolved in EtOAc, washed with saturated sodium bicarbonate, brine, and dried over sodium sulfate. The volatiles were removed *in vacuo* and the crude product 17 ($R_f$ (1:3 EtOAc:hexanes): 0.7) was dissolved in THF (760 mL) and cooled to 0 °C. Potassium *tert*-butoxide (8.94 g, 79.7 mmol) was added portionwise until the reaction was complete by TLC. The solvent was evaporated, the crude redissolved in EtOAc, washed with
saturated sodium bicarbonate, then brine, then dried over sodium sulfate. Compound 18 was purified by recrystallization from hot EtOAc. Yield: 7.6 g, 35% (3 steps), white solid. \( R_f \) (1:3 EtOAc:hexanes): 0.2. 1:1 Mixture of rotamers. \(^1\)H NMR integrations adjusted to reflect whole number protons of each rotamer in solution. \(^1\)H NMR (500 MHz, CDCl\(_3\)) \( \delta \) 8.10 (br. s, 1H), 7.92 (br. s, 1H), 7.37 – 7.25 (m, 3H), 7.22 – 7.16 (m, 1H), 7.16 – 7.03 (m, 3H), 6.92 (d, \( J = 7.9 \) Hz, 2H), 4.55 (br. s, 2H), 4.48 (br. s, 2H), 4.42 (br. s, 2H), 4.29 (br. s, 2H), 1.44 (br. s, 9H), 1.37 (br. s, 9H). \(^1\)C NMR (126 MHz, CDCl\(_3\)) \( \delta \) 171.1, 170.3, 154.4, 153.9, 136.3, 130.2, 129.6, 128.8, 128.6, 127.9, 125.0, 123.9, 120.3, 119.9, 81.1, 80.8, 51.6, 51.2, 49.9, 48.9, 28.2. N-(2-(3,5-dimethyl-4H-1,2,4-triazol-4-yl)benzyl)methanesulfonamide (7). After Boc deprotection of 27 using general procedure B, free amine (1.0 equiv., 48 mg, 0.237 mmol) and triethylamine (1.2 equiv., 39.7 µL, 0.285 mmol) were dissolved in anhydrous dichloromethane (2.4 mL, 0.1 M) in an oven-dried 2-dram vial equipped with magnetic stir bar and rubber septum. The resulting mixture was cooled to 0 ºC and then methanesulfonyl chloride (1.2 equiv., 22 µL, 0.285 mmol) was added. After stirring at 0 ºC for 1 hour, the reaction was warmed to room temperature over 2 hours and then quenched with 5 mL of a saturated solution of sodium bicarbonate. The organic layer was separated and the aqueous layer was extracted with dichloromethane (3x5 mL). The organic extracts were combined, dried over sodium sulfate, filtered, and solvent was removed in vacuo. The crude residue was then purified by reverse-phase
flash-chromatography using a 5-100% MeCN gradient in H₂O with 1% of formic acid. The fractions containing desired product were pooled and lyophilized. Yield: 35%, white solid. ¹H NMR (400 MHz, CD₃OD) δ 2.10 - 2.30 (m, 6H), 2.86 (s, 3H), 3.95 (s, 2H), 7.32 (d, J = 7.7 Hz, 1H), 7.54 - 7.62 (m, 1H), 7.62 - 7.69 (m, 1H), 7.75 (d, J = 7.7 Hz, 1H), 8.46 (s, sulfonamide NH under deuterium exchange). ¹³C NMR (126 MHz, CD₃OD) δ 153.6, 137.1, 133.2, 132.2, 132.0, 130.8, 129.6, 43.4, 40.0, 10.8; HRMS (DART) m/z: [M + H]+ calcd for C₁₂H₁₇N₄O₂S 281.1072, found 281.1070.

2-(3,5-dimethyl-4H-1,2,4-triazol-4-yl)benzoic acid (8). Anhydride 28 (1.0 g, 6.21 mmol, 1.1 equiv.) and acetylhydrazide (418 mg, 5.64 mmol, 1.0 equiv.) were refluxed in EtOH (56 mL, 0.1M) for 3 h. The reaction was cooled down to r.t. and then dry loaded on celite. The crude was purified using C18 functionlized silica gel using a gradient from 5:95 MeCN:H₂O to 1:1 MeCN:H₂O. The fractions containing the desired product were lyophilized. Yield: 27%, white solid. ¹H NMR (500 MHz, DMSO-d₆) δ 13.38 (s, 1H), 8.05 (dd, J = 7.8, 1.6 Hz, 1H), 7.78 (dt, J = 7.7, 1.7 Hz, 1H), 7.68 (dt, J = 7.6, 1.3 Hz, 1H), 7.49 (dd, J = 7.8, 1.3 Hz, 1H), 2.01 (s, 6H). ¹³C NMR (126 MHz, DMSO-d₆) δ 165.8, 150.5, 133.6, 133.0, 131.5, 130.3, 129.6, 129.6, 10.6. **N-(N²-(tert-butoxycarbonyl)-N⁶,N⁶-dimethyl-L-lysyl)-O-(tert-butyl)-L-seryl)-O-(tert-butyl)-L-threonylglycine (40).** Tetrapeptide 38 was synthesized using standard chloro-trityl resin for solid phase peptide synthesis using 1.0 g of resin (1 mmol). 38 (400 mg, 0.542 mmol, 1.0 equiv.) was dissolved in 1.1 mL of MeOH (0.5 M) and added AcOH (124 µL, 2.17 mmol, 4.0 equiv.) and the solution was charged in Pd on carbon (29 mg, 0.027 mmol, 5 mol%). The resulting solution was stirred under a H2 atmosphere for 12 h. The reaction was monitored by LC-MS. Upon completion of the reaction, the resulting crude was filtered through celite and the product concentrated to give peptide 39 in quantitative yield. Peptide 39 was then dissolved in MeOH and formaldehyde (149 µL, 1.63 mmol, 3.0 equiv., 37% aq. solution) was added and stirred 20 min at room temperature. NaBH₃CN (136 mg, 2.17 mmol, 4.0 equiv.) was added and the reaction stirred for 8 h at room temperature. The reaction was slowly quenched with 1 M HCl until no more bubbling was observed. The resulting mixture was then dry loaded in celite and purified using C18 functionalized silica column using a gradient from 5:95 MeCN:H2O to 95:5 MeCN:H2O with 0.1% formic acid as an additive. The fractions containing 40 were lyophilized. Yield: 291 mg, 85%,
white solid. $^1$H NMR (500 MHz, DMSO-$d_6$) $\delta$ 8.17 (d, $J = 8.0$ Hz, 1H), 7.61 (t, $J = 5.5$ Hz, 1H), 7.37 (d, $J = 7.7$ Hz, 1H), 6.87 (d, $J = 8.2$ Hz, 1H), 4.35 (dt, $J = 8.7$, 4.6 Hz, 1H), 4.15 (dd, $J = 7.7$, 3.2 Hz, 1H), 4.05 (dt, $J = 8.3$, 4.8 Hz, 1H), 3.99 (dq, $J = 6.3$, 3.1 Hz, 1H), 3.68 – 3.54 (m, 2H), 3.54 – 3.38 (m, 2H), 2.75 (dt, $J = 12.0$, 7.7 Hz, 1H), 2.59 – 2.53 (m, 2H), 2.47 (s, 6H), 1.64 (dd, $J = 15.2$, 5.9 Hz, 1H), 1.58 – 1.45 (m, 3H), 1.37 (s, 9H), 1.27 (dd, $J = 21.3$, 11.4, 5.8 Hz, 1H), 1.13 (d, $J = 1.7$ Hz, 19H), 0.99 (d, $J = 6.3$ Hz, 3H).

$^{13}$C NMR (126 MHz, DMSO-$d_6$) $\delta$ 172.7, 172.5, 170.0, 169.1, 164.1, 155.7, 78.4, 74.2, 73.4, 66.8, 62.1, 58.1, 57.2, 54.1, 54.1, 43.2, 42.9, 40.9, 31.8, 28.6, 28.3, 27.5, 24.7, 23.0, 19.2. HRMS (DART) m/z: [M + H]$^+$ calcd for C$_{35}$H$_{58}$N$_5$O$_9$ 632.4235, found 632.4242.

(S)-N-((S)-1-(((2S,3R)-1-((2-((4-(2-(acetamidomethyl)phenyl)-5-methyl-4H-1,2,4-triazol-3-yl)methyl)amino)-2-oxoethyl)amino)-3-hydroxy-1-oxobutan-2-yl)amino)-3-hydroxy-1-oxopropan-2-yl)-2-amino-6-(dimethylamino)hexanamide (10). Compound 40 (155 mg, 0.245 mmol, 1.0 equiv.) was dissolved in 2.5 mL of DCM (0.1M) and EDC•HCl (70 mg, 0.368 mmol, 1.5 equiv.) was added in one portion and stirred the resulting mixture for 20 min. Amine 37 (95 mg, 0.368 mmol, 1.5 equiv.) was added and the reaction stirred for 6 h at room temperature. The progress of the reaction was monitored by LC-MS. Upon complete consumption of 40, the reaction was dry loaded in celite and quickly purified using C18 functionalized silica using a gradient from 5:95 MeCN:H$_2$O to 95:5 MeCN:H$_2$O with 0.1% formic acid as an additive. The fractions containing coupled product were lyophilized and then treated with 2.5 mL a 95:2.5:2.5 TFA:H$_2$O:triethylsilane for 3 h. TFA was then removed by blowing nitrogen into the reaction vessel. The resulting concentrate was redissolved in MeOH and IRA-67 resin was added until the pH of the solution reached ~ 8. This mixture containing the resin was then dry loaded in celite dry and purified using C18 functionalized silica using a gradient from 0:100 MeCN:H$_2$O to 15:85
MeCN:H₂O (no formic acid as additive in order to isolate the free amine). The fractions containing 10 were lyophilized for isolation. Yield: 48 mg, 30%, white solid. ¹H NMR (500 MHz, DMSO-d₆) δ 8.67 (t, J = 7.2 Hz, 1H), 8.45 (dt, J = 5.9, 1.4 Hz, 1H), 8.30 – 8.23 (m, 2H), 8.00 (dt, J = 7.6, 5.8 Hz, 1H), 7.86 (dd, J = 8.1, 3.0 Hz, 1H), 7.55 (dt, J = 7.5, 1.3 Hz, 1H), 7.50 – 7.47 (m, 1H), 7.44 (dt, J = 7.6, 1.6 Hz, 1H), 7.30 (ddd, J = 7.8, 3.2, 1.3 Hz, 1H), 4.46 (q, J = 6.1 Hz, 1H), 4.20 (ddd, J = 8.0, 6.0, 3.5 Hz, 1H), 4.17 – 4.09 (m, 2H), 4.05 (ddd, J = 6.2, 3.6, 2.4 Hz, 1H), 3.90 – 3.78 (m, J = 6.0 Hz, 2H), 3.77 – 3.64 (m, 2H), 3.64 – 3.55 (m, 3H), 2.60 (dt, J = 7.2, 2.4 Hz, 2H), 2.43 (s, 6H), 2.11 (s, 3H), 1.83 (d, J = 2.4 Hz, 3H), 1.67 (ddq, J = 36.5, 14.0, 7.1 Hz, 2H), 1.50 (ddd, J = 13.4, 8.0, 4.4 Hz, 2H), 1.34 (p, J = 7.3, 6.8 Hz, 2H), 1.03 (dd, J = 6.4, 1.5 Hz, 3H). ¹³C NMR (126 MHz, DMSO-d₆) δ 170.34, 170.3, 170.2, 170.2, 170.0, 169.4, 169.4, 168.4, 151.6, 151.3, 136.8, 136.8, 131.5, 131.5, 131.0, 131.0, 130.3, 128.8, 128.8, 128.4, 128.2, 66.3, 61.6, 58.4, 58.3, 57.2, 55.0, 55.0, 52.5, 43.3, 41.8, 37.6, 33.6, 31.7, 24.8, 22.4, 21.8, 19.7, 19.7, 10.3. HRMS (DART) m/z: [M + H]⁺ calcd for C₃₀H₄₉N₁₀O₇ 661.3780, found 661.3772.
