Cadmium (Cd\(^{+2}\)) is a potential and widespread toxic environmental pollutant, mainly derived from a rapid industrial process that has inhibitory effects on growth, physiological, and biochemical attributes of various plant species, including medicinal plants such as *Silybum marianum* L. Gaertn commonly known as milk thistle. Plant signaling molecules, when applied exogenously, help to enhance/activate endogenous biosynthesis of potentially important signaling molecules and antioxidants that boost tolerance against various abiotic stresses, e.g., heavy metal stress. The present study documented the protective role of salicylic acid (SA; 0.25 \(\mu\)M) and hydrogen peroxide (H\(_2\)O\(_2\); 10 \(\mu\)M) priming, foliar spray, and combinational treatments in reducing Cd\(^{+2}\) toxicity (500 \(\mu\)M) in milk thistle grown at two diverse ecological zones of Balochistan Province of Pakistan i.e., Quetta (Qta) and Turbat (Tbt). The morpho-physiological and biochemical attributes of milk thistle were significantly affected by Cd\(^{+2}\) stress; however, priming and foliar spray of SA and H\(_2\)O\(_2\) significantly improved the growth attributes (root/shoot length, leaf area, and root/shoot fresh and dry weight), photosynthetic pigments (Chl a, b, and carotenoids) and secondary metabolites (Anthocyanin, Soluble phenolics, and Tannins) at both altitudes by suppressing the negative impact of Cd\(^{+2}\). However, the oxidative damage parameters, i.e., MDA and H\(_2\)O\(_2\), decreased astonishingly under the treatment of signaling molecules, thereby protecting membrane integrity under Cd\(^{+2}\) stress. The morphological variations were profound at the low altitude (Tbt) as compared to the high altitude (Qta). Interestingly,
INTRODUCTION

Milk thistle (Silybum marianum L. Gaertn) is a medicinal weed belonging to the Asteraceae family. It grows well at an altitude of 1,800–2,400 m a.s.l in sandy or rocky soil. The optimum temperature for germination of milk thistle seeds ranges between 28 and 29°C. The density of plants reaches up to 4.5 plant/m² (Karkanis et al., 2011; Heidari et al., 2014). Medicinal plants are of very high significance because they provide the community with health care and prevention from diseases. A rapid increase in the population and pharmaceutical industry needs medicinally important plants with active ingredients to enhance and promote their cultivation and production (Valková et al., 2021; Zahra et al., 2021c). Compounds of pharmaceutical properties are derived from milk thistle fruits, i.e., achenes. Seed and dry pericarp accumulate a large flavonolignans group called silymarin, being the precursor taxifolin (Bijak, 2017).

The environmental contamination to heavy metals and other pollutants hailing from the eighteenth century (Andrade et al., 2014) in which cadmium (Cd²⁺) is the most toxic heavy metal for the living biota (Raza et al., 2020). Heavy metals toxicity has been widely recognized (Raza et al., 2021a, 2022; Salehi et al., 2021; Zahra et al., 2021a). Cd²⁺ is a non-degradable trace metal contaminant, ranked seventh among the top recognized pollutants in the environment. When Cd²⁺ enters the cells of plants, it interferes and disrupts the metabolic process because of an interaction with some organic compounds within organelles of cells and the cytosol (Ali et al., 2013; Mwamba et al., 2020; Raza et al., 2020). Furthermore, it may interact with proteins and lipids that result in affecting the enzyme and fluidity of the membrane by causing oxidative damage that initiates free radical formation (Yu et al., 2018; Mwamba et al., 2020; Raza et al., 2021b, 2022). It binds to sulphydryl groups in proteins that also replace the important metal ions metalloproteins (Raza et al., 2021c). The mountainous areas plants, in contrast to land plants, display changes in physiognomy, anatomy, and physiology. Plant characteristics can be divided into two groups with the elevation changes. The variations of recorded data confirmed the higher antioxidant activity of plant extracts, which were derived from low to high altitude (Spitaler et al., 2008).

Salicylic acid is widely used to promote the plants’ growth and their development under varying favorable and unfavorable conditions of the ambient environment. SA has a crucial role in mediating the responses to the toxicity of heavy metals. Recently, it has been reported that SA ameliorates Cd²⁺ stress by improving germination and protecting membrane (Lu et al., 2018; Majumdar et al., 2020). Hydrogen peroxide (H₂O₂) is recognized as one of the main chemicals, having the properties of inducing tolerance under biotic and abiotic stress (Dikilitas et al., 2020). H₂O₂ as a signaling molecule also plays a key role within plants and acts as a messenger molecule involved in signaling, which triggers stress tolerance against different stresses of abiotic conditions. Growing milk thistle across the altitudinal gradient for exploring the tolerance potential under Cd²⁺ toxicity is a pragmatic approach to exploring the mechanisms for its tolerance and survival in diverse environmental regimes. Recently, variation in morpho-physiological attributes has been reported with different milk thistle ecotypes grown at a single ecological zone under different stresses (Zahra et al., 2021b,d). However, the information about Cd²⁺ tolerance of milk thistle under priming and foliar of H₂O₂ and SA, grown at the diverse ecological zones, is still lacking. The data on morpho-physiological attributes of milk thistle grew at varying altitudes under Cd²⁺ stress are not reported from Balochistan, Pakistan. In the present study, an effort has been made to explore the tolerance potential of milk thistle to Cd²⁺ stress under priming and foliar treatments of H₂O₂ and SA grown at the Quetta and Turbat area of Balochistan, Pakistan.

MATERIALS AND METHODS

Experimental Detail

A study was planned to explore/evaluate the role of H₂O₂ and SA in alleviating cadmium toxicity in milk thistle that was grown across the altitudinal gradient, i.e., at Quetta (1,679 m) and Turbat (129 m). Both areas have diverse environmental regimes with varying maximum and minimum temperatures around the year (Figure 1). A Randomized Complete Block Design (RCBD) experiment was designed in which the field was divided into two major plots: control and cadmium (500 µM). Each plot further contained ten treatments with three replicates. The experimental plot was 57 × 12 feet (each plot, i.e., control and cadmium) at both experimental sites. Here, control treatment means no foliar and no priming treatment in both cadmium treated and untreated plants/control plants). Prior to the sowing of seeds, the soil of both experimental sites was analyzed for its physico-chemical properties (Table 1). Seeds were sown at 1-inch depth, row to row, and plant-to-plant distance was 1 ft.

Priming and Foliar Spray

Seeds of milk thistle were collected from Balochistan Agriculture Research and Development Centre (BARDC), Quetta for experiment. The seeds of milk thistle were primed in concentrations of 0.25 µM salicylic acid (SA), 10-µM hydrogen peroxide (H₂O₂), and with distilled water (H₂O) for 8 h, and
then seeds were sown in the field. After 15 days of germination, Cd\(^{2+}\) was applied at both altitude fields with a concentration of 500 \(\mu\)M. These concentrations were selected based on our preliminary trial (data not shown); thus, one suitable level was selected for the present study. In the field of cadmium, a black sheet was placed at 5-foot depth in order to avoid its leaching. After 15 days of cadmium treatment, plants were foliarly treated using the same level of SA, \(H_2O_2\) treatment as used for priming (P). Moreover, after 15 days of foliar spray (FS), the milk thistle plants were harvested from both experimental sites, and data were recorded for various morpho-physiological attributes.

### Physiological Analysis

#### Photosynthetic Pigment Analysis

Leaf samples (0.1 g) were extracted with acetone (80%). The absorbance was recorded at 663 nm, 645 nm and 480 nm against 80% acetone (Arnon, 1949; Kirk and Allen, 1965). Chlorophyll \(a\), \(b\), and carotenoids contents were measured using the following formulas:

- **Chlorophyll \(a\) (mg/g fresh wt.)** = \((1.27 \text{ OD663}) - 2.69 (\text{OD645}) \times \frac{V}{1000 \times W}\)

- **Chlorophyll \(b\) (mg/g fresh wt.)** = \((22.9 \text{ OD645}) - 4.68 (\text{OD663}) \times \frac{V}{1000 \times W}\)

- **Carotenoids (mg/g fresh wt.)** = \((\text{OD480} + 0.114 \text{ OD663}) - 0.638 (\text{OD645})/2500 \times 1000\)

#### Determination of Anthocyanins

For anthocyanins contents determination, 0.1 g of plant sample was taken and extracted in 1–2 ml acidified methanol. The samples were placed in a water bath at 50\(^\circ\)C for 1 h. The absorbance was measured at 535 nm by an spectrophotometer using acidified methanol as blank (Strack and Wray, 1989).

#### Soluble Phenolic

Soluble phenolic was determined by taking 0.1 g of a plant sample by grinding in 1–2 ml of 80% acetone. In the test tube, 1 ml of distilled water was added in 100 \(\mu\)L of the sample, followed by the addition of 0.5 ml folin phenol reagent, and then 2.5 ml of 20% \(Na_2CO_3\) (sodium carbonate) was added. The absorbance at 745 nm was measured using 80% acetone as blank (Julkunen-Tiitto, 1985).

#### Tannins

A sample (root and shoot) was taken and added 2 ml of diethyl ether and left overnight, and then decanted the solution, and 1 ml of 70% acetone was added and kept overnight. From each sample, 50 \(\mu\)L of the extract was taken in each test tube, and the volume was made up to 1 ml with distilled water. After dilution, 0.5 ml of folin phenol reagent was added vortexed, and then added 2.5 ml of 20% \(Na_2CO_3\) solution mixed very well and kept for 40 min at

---

### Determination of Growth Attributes

Root and shoot length (cm), number of leaves, leaf area (cm\(^2\)), root and shoot fresh (g), along with dry weight (g), were determined. Three plant samples were randomly collected for measuring root and shoot length by using a scale, and the number of total leaves/per plant was counted. Plants were harvested carefully. Before harvest, the field was fully watered to make safe and easy removal of roots from soil without any mechanical damage. The area of the leaf was calculated by following an equation developed by Cain and Castro (1959) by using the given formula, \(A = 1/4.75 \times L \times W\). The \(L\) described the length of the leaf, while \(W\) showed the width of the leaf, and 0.75 was being utilized for the correction factor that was used for conservation of the leaf length and width rectangular product into the area of the leaf. Lastly, three roots and shoots were separately weighted to determine the fresh weight (FW) and placed in an oven (65–75\(^\circ\)C, 72 h) to obtain dry weight (DW).

---

### Table 1: Physio-chemical analysis of the soil of experimental sites.

| Region   | Exchangeable potassium (mg/kg) | Available phosphorus (mg/kg) | Total nitrogen (mg/kg) | Cadmium (mg/kg) | Organic matter (%) | \(pH\) | Electrical conductivity (dS/m) |
|----------|-------------------------------|-----------------------------|------------------------|----------------|-------------------|------|-----------------------------|
| Quetta   | 241                           | 4.9                         | 0.275                  | 0.36           | 0.502             | 8.05 | 1.52                        |
| Turbat   | 197                           | 4.1                         | 0.165                  | 0.31           | 0.196             | 7.84 | 9.08                        |

room temperature. The absorbance was recorded at 725 nm using 70% acetone as a blank.

**Hydrogen Peroxide (H\textsubscript{2}O\textsubscript{2})**

Fresh plant samples (0.1 g) were grinded in 2 ml of 0.1% (w/v) trichloroacetic acid (TCA) under pre-chilled conditions by crushing the tissues (placed on ice bath). The homogenized material was then centrifuged at 12,000 rpm for 15 min. The supernatant (0.5 ml) was mixed with 0.5 ml of a potassium phosphate buffer (pH 7.0), and 1 ml of potassium iodide solution, thoroughly mixed, and absorbance was recorded at 390 nm. Distilled water was used as a blank (Velikova et al., 2000).

**Malondialdehyde**

Malondialdehyde (MDA) was determined by the method developed by Heath and Packer (1968). A plant sample (0.1 g) of plant fresh material was grinded in 1 ml of (1% w/v) TCA and centrifuged at 12,000 rpm for 15 min. About 1 ml of supernatant was taken and mixed with 1 ml of 0.5% thiobarbituric acid in 20% TCA [0.5% in 20% (w/v) TCA] and kept in a water bath preheated at 95°C for 50 min. The sample extract was cooled in an ice bath. Absorbance was measured at 532 nm and 600 nm. For comparison, 1% TCA was used as a blank. MDA contents were calculated using their absorption coefficient of 155,000 nmol/mol as:

\[
\text{MDA[nmol/ml}^{-1} = (A532 - A600)/155,000]10^6
\]

**Statistical Analysis**

The recorded data from each parameter were analyzed statistically using “STATISTIX 8.1.” The graphs and mean standard deviation were calculated using MS. EXCEL.

**RESULTS**

** Morphological Parameters**

**Root Length**

Results were obtained for the root length of milk thistle grown at two different altitudes (Qta and Tbt), under Cd\textsuperscript{2+} toxicity (500 \(\mu\)M) showed statistically significant results (Figure 2B) \((p < 0.05)\). Results revealed that treatment of SA priming + foilar spray (P + FS) under control at high-altitude Qta was best, while the treatment of salicylic acid FS under control was the least effective. However, the priming and foliar spray helped to reduce the impact of Cd\textsuperscript{2+} toxicity in milk thistle grown at Qta and Tbt (Figure 2B).

The trend of root length at Qta was SA P + FS control > H\textsubscript{2}O priming control > H\textsubscript{2}O\textsubscript{2} P + FS control > H\textsubscript{2}O P + FS Cd\textsuperscript{2+} > H\textsubscript{2}O priming control > H\textsubscript{2}O\textsubscript{2} spray control > H\textsubscript{2}O P + FS Cd\textsuperscript{2+} > Control of Control > SA P + FS Cd\textsuperscript{2+} > SA spray Cd\textsuperscript{2+} > Control Cd\textsuperscript{2+} > H\textsubscript{2}O spray control > SA priming control > H\textsubscript{2}O spray Cd\textsuperscript{2+} > SA priming Cd\textsuperscript{2+} > H\textsubscript{2}O P + FS Cd\textsuperscript{2+} > SA spray control.

Considering Tbt, the trend observed for root length was as follows: H\textsubscript{2}O\textsubscript{2} spray control > SA P + FS control > SA spray control > H\textsubscript{2}O priming control > H\textsubscript{2}O P + FS control > H\textsubscript{2}O priming Cd\textsuperscript{2+} > H\textsubscript{2}O\textsubscript{2} P + FS Cd\textsuperscript{2+} > H\textsubscript{2}O spray control > SA priming Cd\textsuperscript{2+} > H\textsubscript{2}O\textsubscript{2} priming control > H\textsubscript{2}O P + FS Cd\textsuperscript{2+} > H\textsubscript{2}O priming Cd\textsuperscript{2+} > H\textsubscript{2}O\textsubscript{2} spray Cd\textsuperscript{2+} > SA spray Cd\textsuperscript{2+} > Control of Control > H\textsubscript{2}O spray Cd\textsuperscript{2+} > control Cd\textsuperscript{2+} (Control; no foliar no priming treatment in both cadmium-treated and -untreated plants/control plants).

In a nutshell, the root length of milk thistle at both altitudes affected under Cd\textsuperscript{2+} toxicity; however, the priming and foliar application of Hydrogen peroxide (H\textsubscript{2}O\textsubscript{2}) and salicylic acid (SA) helped significantly to reduce the impacts of Cd\textsuperscript{2+} toxicity in milk thistle (Figure 2B).

**Shoot Length**

Data recorded for shoot length of milk thistle grown at two different altitudes (Qta and Tbt) under Cd\textsuperscript{2+} toxicity (500 \(\mu\)M) reported statistically significant results \((p < 0.05)\) in which H\textsubscript{2}O\textsubscript{2} P + FS treatment at high-altitude Qta under control conditions produced plants with greater shoot length while minimum shoot length was observed in SA P + FS of Qta under Cd\textsuperscript{2+} stress. Milk thistle at low altitude (Tbt) had healthy plants as compared to Qta, which demonstrated that the temperature of Tbt supported enhancing the growth of plants’ ambient conditions (Figure 2A).

The order of improvement at Qta was observed as H\textsubscript{2}O\textsubscript{2} P + FS control > SA P + FS control > Control of Control > H\textsubscript{2}O priming control > H\textsubscript{2}O P + FS control > control Cd\textsuperscript{2+} > H\textsubscript{2}O priming control > H\textsubscript{2}O\textsubscript{2} priming Cd\textsuperscript{2+} > SA priming control > H\textsubscript{2}O P + FS Cd\textsuperscript{2+} > H\textsubscript{2}O priming Cd\textsuperscript{2+} > SA spray Cd\textsuperscript{2+} > SA priming Cd\textsuperscript{2+} > H\textsubscript{2}O priming Cd\textsuperscript{2+} > H\textsubscript{2}O spray Cd\textsuperscript{2+} > SA spray control > SA P + FS Cd\textsuperscript{2+}.

However, the order for growth in Tbt was H\textsubscript{2}O\textsubscript{2} P + FS control > SA spray control > H\textsubscript{2}O P + FS control > H\textsubscript{2}O priming control > SA P + FS control > Control of Control > SA priming control > H\textsubscript{2}O\textsubscript{2} spray control > H\textsubscript{2}O priming control > H\textsubscript{2}O spray Cd\textsuperscript{2+} > control Cd\textsuperscript{2+} > H\textsubscript{2}O priming Cd\textsuperscript{2+} > SA priming Cd\textsuperscript{2+} > SA P + FS Cd\textsuperscript{2+} > H\textsubscript{2}O P + FS Cd\textsuperscript{2+} > SA spray Cd\textsuperscript{2+} > H\textsubscript{2}O\textsubscript{2} Cd\textsuperscript{2+} > H\textsubscript{2}O P + FS Cd\textsuperscript{2+}.

Overall, it has been observed that the priming and foliar spray with SA and H\textsubscript{2}O\textsubscript{2} decreased the toxic effects of Cd\textsuperscript{2+} in milk thistle. However, in control conditions, both plant signaling molecules helped to significantly enhance the shoot length (Figure 2A).

**Number of Leaves**

Results obtained for the number of leaves of milk thistle plants grown at both the altitudes of Qta along with Tbt under the concentration of 500-\(\mu\)M Cd\textsuperscript{2+} stress displayed highly significant \((p < 0.05)\) data (Figure 3D). Data for leaves count from respective treatment revealed that the highest number of leaves was recorded from H\textsubscript{2}O\textsubscript{2} P + FS under control conditions at low-altitude Tbt, while the less number of leaves counted from SA spray under control of Qta (Figure 3D).

In Qta, the order was observed as SA P + FS control > H\textsubscript{2}O\textsubscript{2} P + FS control > H\textsubscript{2}O priming control > H\textsubscript{2}O P + FS control > Control of Control > SA priming control > SA spray Cd\textsuperscript{2+} > H\textsubscript{2}O spray control > H\textsubscript{2}O priming control > H\textsubscript{2}O\textsubscript{2} priming control > H\textsubscript{2}O priming Cd\textsuperscript{2+} > H\textsubscript{2}O spray Cd\textsuperscript{2+} > SA spray Cd\textsuperscript{2+} > Control of Control > H\textsubscript{2}O spray Cd\textsuperscript{2+} > control Cd\textsuperscript{2+} > H\textsubscript{2}O priming Cd\textsuperscript{2+} > SA priming Cd\textsuperscript{2+} > SA P + FS Cd\textsuperscript{2+} > H\textsubscript{2}O P + FS Cd\textsuperscript{2+} > SA spray Cd\textsuperscript{2+} > H\textsubscript{2}O\textsubscript{2} Cd\textsuperscript{2+} > H\textsubscript{2}O P + FS Cd\textsuperscript{2+}.
spray Cd$^{+2}$ > H$_2$O$_2$ P + FS Cd$^{+2}$ > control Cd$^{+2}$ > H$_2$O spray control > H$_2$O P + FS Cd$^{+2}$ > SA priming Cd$^{+2}$ > H$_2$O priming Cd$^{+2}$ > SA spray control.

While the order of treatments at Tbt was denoted as H$_2$O P + FS control > H$_2$O priming control > H$_2$O$_2$ P + FS control > SA P + FS control > SA spray control > H$_2$O$_2$ priming control > H$_2$O spray control > H$_2$O$_2$ spray Cd$^{+2}$ > Control of Control > SA priming control > control Cd$^{+2}$ > H$_2$O$_2$ priming Cd$^{+2}$ > H$_2$O priming Cd$^{+2}$ > SA spray Cd$^{+2}$ > H$_2$O spray Cd$^{+2}$ > SA P + FS Cd$^{+2}$ > H$_2$O P + FS Cd$^{+2}$ > SA priming Cd$^{+2}$ > H$_2$O$_2$ P + FS Cd$^{+2}$.

Considering the total number of leaves among the treatments of both altitudes, it has been observed that, under control conditions, milk thistle was reported to have flourished well as compared to Cd$^{+2}$ stress, while H$_2$O$_2$ and SA

**FIGURE 2** | Growth parameters; shoot length (A), root length (B), shoot fresh weight (C), shoot dry weight (D) of milk thistle as affected by SA and H$_2$O$_2$ treatment grown at Quetta and Turbat under cadmium stress. The same letters on graphs represent statistically similar effect ($p < 0.05$).
priming with foliar spray decreased the impact of Cd$^{+2}$ toxicity (Figure 3D).

**Leaf Area**

Data recorded for leaf area of milk thistle grew at two different altitudes (Qta and Tbt) under 500-µM Cd$^{+2}$ concentration reported significant ($p < 0.05$) results statistically (Figure 3C). Results for the leaf area revealed that the greater leaf area was recorded from H$_2$O$_2$ P + FS of control at high-altitude Qta, while the lowest was observed for SA spray of control under same-altitude Qta (Figure 3C).

The order of leaf area improvement at Qta was observed as H$_2$O$_2$ P + FS > SA P + FS > H$_2$O P + FS > Control of Control > H$_2$O$_2$ priming control > H$_2$O$_2$ spray control > H$_2$O$_2$ priming Cd$^{+2}$ > Control Cd$^{+2}$ > H$_2$O priming Cd$^{+2}$ > SA priming control > SA spray Cd$^{+2}$ > H$_2$O P + FS Cd$^{+2}$ > H$_2$O$_2$ P + FS Cd$^{+2}$ > SA P + FS...
Cadmium Tolerance in Milk Thistle

Nizar et al.

Cd$^{2+}$ > H$_2$O spray control > H$_2$O spray Cd$^{2+}$ > SA priming Cd$^{2+}$ > SA spray control.

While order of improvement at Tbt was much better as compared to Qta that is as follows: H$_2$O P + FS control > Control of Control > H$_2$O priming control > H$_2$O$_2$ P + FS control > H$_2$O$_2$ spray control > Control Cd$^{2+}$ > H$_2$O spray Cd$^{2+}$ > Control Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > SA spray Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$ > SA priming Cd$^{2+}$ > H$_2$O spray Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > SA P + FS Cd$^{2+}$ > H$_2$O P + FS Cd$^{2+}$ > SA spray Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$.

Considering the leaf area of both altitudinal fields, results favor a considerable enhancement of the leaf area at Tbt under control as compared to Qta plants. It is also recorded that H$_2$O$_2$ and SA priming + foliar spray hampered the impact of Cd$^{2+}$ toxicity much better at low-altitudinal field Tbt as compared to Qta (Figure 3C).

Root Fresh Weight

Data obtained for root fresh weight of milk thistle comprising at both altitudinal fields, i.e., Qta and Tbt under Cd$^{2+}$ stress reported significant results statistically (p < 0.05) described in Figure 3A. Results indicated that maximum root fresh weight was observed in H$_2$O$_2$ P + FS treatment under control at high-altitude Qta. However, the minimum weight was recorded from H$_2$O$_2$ spray under Cd$^{2+}$ stress at the same altitude (Figure 3A).

The order of improvement of Qta was observed as H$_2$O$_2$ P + FS control > SA P + FS control > SA spray control > H$_2$O P + FS control > H$_2$O$_2$ spray control > Control of Control > Control Cd$^{2+}$ > SA priming Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > H$_2$O P + FS Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$.

While, under low-altitude Tbt, the order of treatment was H$_2$O$_2$ P + FS control > H$_2$O$_2$ priming control > SA P + FS control > SA spray control > H$_2$O P + FS control > H$_2$O$_2$ spray control > Control of Control > Control Cd$^{2+}$ > SA priming Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > H$_2$O P + FS Cd$^{2+}$ > H$_2$O$^2$ spray Cd$^{2+}$.

Conclusively, data revealed that, under Qta control, there was the maximum fresh weight of the root in contrast with Tbt control. However, considering Cd$^{2+}$, the root fresh weight of Tbt resulted in having much improvement as compared to Cd$^{2+}$ at Qta (Figure 3A). Overall results indicate a minimum root fresh weight, among which H$_2$O$_2$ and SA were quite effective in enhancing the root fresh weight of milk thistle to a very significant extent at both the altitudes (Figure 3A).

Shoot Fresh Weight

Data recorded for shoot fresh weight of milk thistle grown at two different altitudes (Qta and Tbt) statistically reported significant (p < 0.05) results (Figure 2C). Results revealed that H$_2$O P + FS under control of area Tbt showed greater shoot fresh weight, while the lower shoot fresh weight was observed in SA spray under control at Qta (Figure 2C).

The order of shoot fresh weight at Qta was recorded as SA P + FS control > H$_2$O$_2$ P + FS control > Control of Control > H$_2$O P + FS control > H$_2$O$_2$ priming control > H$_2$O$_2$ spray control > Control Cd$^{2+}$ > H$_2$O$_2$ priming control > H$_2$O$_2$ spray Cd$^{2+}$ > SA priming control > H$_2$O$_2$ priming Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > H$_2$O P + FS Cd$^{2+}$ > SA spray Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > SA spray control.

While, under low-altitude Tbt, the order of improvement reported was H$_2$O P + FS control > SA spray control > H$_2$O$_2$ P + FS control > SA P + FS control > SA spray control > SA priming control > Control Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > H$_2$O spray Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > SA priming Cd$^{2+}$ > SA P + FS Cd$^{2+}$ > SA spray Cd$^{2+}$ > H$_2$O P + FS Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$.

In a nutshell, the observed data for shoot fresh weight revealed that the low-altitudinal field Tbt reported highly significant variations under control and Cd$^{2+}$ toxicity in contrast with Qta. On the other hand, the application of SA along with H$_2$O$_2$ helped to suppress Cd$^{2+}$ stress and enhance shoot fresh weight of milk thistle grown at Tbt, which describes a very healthy and effective growth of milk thistle at low altitude (Figure 2C).

Root Dry Weight

Results obtained for root dry weight of milk thistle grown at two varying altitudes (Qta and Tbt) under Cd$^{2+}$ toxicity reported statistically significant results (p < 0.05) by revealing that the highest value for root dry weight was observed in H$_2$O$_2$ P + FS under control at Qta, while the minimum root dry weight was obtained from SA spray in control at Qta (Figure 3B).

At Qta, the order of treatment was H$_2$O$_2$ P + FS control > SA P + FS control > H$_2$O$_2$ P + FS control > SA priming control > H$_2$O$_2$ spray control > H$_2$O$_2$ priming Cd$^{2+}$ > H$_2$O$_2$ priming control > Control of Control > H$_2$O$_2$ priming control > H$_2$O$_2$ spray Cd$^{2+}$ > SA spray Cd$^{2+}$ > SA P + FS Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > SA P + FS Cd$^{2+}$ > H$_2$O spray Cd$^{2+}$ > Control Cd$^{2+}$ > SA priming Cd$^{2+}$ > H$_2$O$_2$ spray control > SA spray control.

While, at Tbt, the trend observed for root dry weight was as follows: H$_2$O$_2$ priming control > SA spray control > H$_2$O P + FS control > H$_2$O$_2$ P + FS control > H$_2$O$_2$ priming control > SA P + FS control > Control Cd$^{2+}$ > SA priming control > H$_2$O$_2$ priming Cd$^{2+}$ > H$_2$O$_2$ spray control > H$_2$O spray Cd$^{2+}$ > SA P + FS Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > H$_2$O P + FS Cd$^{2+}$ > Control Cd$^{2+}$ > SA priming Cd$^{2+}$ > H$_2$O$_2$ spray control > SA spray control.

Conclusively, the statistical analysis for root dry weight revealed that milk thistle showed a significant variation in root dry weight at both altitudes. However, under control, SA and H$_2$O$_2$ proved to be effective, moreover it also reduced the impacts of Cd$^{2+}$ toxicity (Figure 3B).
**Shoot Dry Weight**

Data obtained for shoot dry weight of milk thistle grown at two different altitudes, i.e., Qta and Tbt, revealed statistically significant ($p < 0.05$) differences under Cd$^{2+}$ toxicity (Figure 2D). Data revealed that, under Cd$^{2+}$ stress, SA and H$_2$O$_2$ supplementations were effective in increasing shoot dry weights. Maximum weight was recorded in SA spray under control at Tbt, while the least was observed in SA spray under control of Qta, which illustrates that the supplementation with signaling molecules at Tbt performed better (Figure 2D).

However, the order of improvement recorded at Qta was SA P + FS control > H$_2$O$_2$ P + FS control > Control of Control > H$_2$O P + FS control > H$_2$O$_2$ priming control > H$_2$O priming control > SA spray Cd$^{2+}$ > SA priming Cd$^{2+}$ > H$_2$O$_2$ priming Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > H$_2$O$_2$ priming Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$ > H$_2$O priming Cd$^{2+}$ > SA P + FS Cd$^{2+}$ > H$_2$O spray Cd$^{2+}$ > H$_2$O P + FS Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > Control Cd$^{2+}$ > SA priming Cd$^{2+}$ > SA spray Cd$^{2+}$.

While, at low-altitude Tbt, the order was SA spray control > H$_2$O$_2$ P + FS control > H$_2$O$_2$ priming control > H$_2$O$_2$ P + FS control > H$_2$O$_2$ priming control > SA P + FS control > Control of Control > SA priming control > H$_2$O$_2$ Spray control > H$_2$O$_2$ priming Cd$^{2+}$ > H$_2$O$_2$ spray control > H$_2$O$_2$ spray Cd$^{2+}$ > Control Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > H$_2$O$_2$ priming Cd$^{2+}$ > SA priming Cd$^{2+}$ > SA P + FS Cd$^{2+}$ > SA spray Cd$^{2+}$ > H$_2$OP + FS Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$.

Considering the overall improvement of milk thistle shoot dry weight, it can be observed that respective treatments at Tbt showed highly significant results reducing toxicity of Cd$^{2+}$. While, at Qta, the SDW reduced to a greater extent both under control and Cd$^{2+}$ conditions. The fluctuating temperature may have a profound effect on the growth of the milk thistle; therefore, a varying trend can be recorded in shoot dry weight (Figure 2D).

**Photosynthetic Pigments**

**Chlorophyll a**

Results obtained for chlorophyll a of milk thistle grown at two varying altitudes (Qta and Tbt) under Cd$^{2+}$ stress of 500-µM concentration revealed statistically non-significant ($p > 0.05$) (Figure 4A). The data further revealed that the maximum Chl a content was observed in H$_2$O$_2$ P + FS under control at Qta, while the minimum Chl a content was recorded in the control field at Tbt (Figure 4A).

However, the trend observed in Qta was H$_2$O$_2$ P + FS control > SA P + FS control > SA spray Cd$^{2+}$ > H$_2$O$_2$ priming Cd$^{2+}$ > H$_2$O$_2$ priming control > H$_2$O$_2$ P + FS control > H$_2$O$_2$ spray Cd$^{2+}$ > SA priming Cd$^{2+}$ > H$_2$O$_2$ priming Cd$^{2+}$ > SA priming Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > Control Cd$^{2+}$ > SA spray Cd$^{2+}$ > Control Cd$^{2+}$ > SA P + FS Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$ > H$_2$O$_2$ priming Cd$^{2+}$ > SA spray Cd$^{2+}$ > H$_2$OP + FS Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$.

While the order of improvement at Tbt was observed as H$_2$O$_2$ spray control > H$_2$O$_2$ spray control > H$_2$O$_2$ P + FS control > H$_2$O$_2$ priming control > SA P + FS control > SA priming control > FS Cd$^{2+}$ > SA priming Cd$^{2+}$ > H$_2$O P + FS control > H$_2$O$_2$ spray Cd$^{2+}$ > H$_2$O$_2$ priming Cd$^{2+}$ > H$_2$O$_2$ priming control > Control of Control.

**Chlorophyll b**

Data recorded for chlorophyll b of milk thistle grown at two different altitudes, i.e., Qta and Tbt, under toxicity of heavy metal (Cd$^{2+}$) of 500-µM concentration showed statistically non-significant ($p > 0.05$) results (Figure 4B), in which data depict that SA P + FS under control of Qta was the best treatment, while H$_2$O$_2$ priming under Cd$^{2+}$ stress at low-altitude Tbt proved to be the least non-significant treatment for chlorophyll b content (Figure 4B).

At high altitude (Qta), the trend recorded for Chl b was H$_2$O$_2$ P + FS control > H$_2$O$_2$ spray control > Control Cd$^{2+}$ > SA priming Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > SA priming control > H$_2$O$_2$ priming control > SA P + FS Cd$^{2+}$ > SA spray Cd$^{2+}$ > H$_2$O$_2$ priming Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$ > Control of Control > SA P + FS control > SA spray control > H$_2$O$_2$ priming control > H$_2$O$_2$ spray control > H$_2$O$_2$ P + FS Cd$^{2+}$.

However, at low altitude (Tbt), the trend was observed as SA P + FS control > SA priming control > Control of Control > H$_2$O$_2$ priming control > H$_2$O$_2$ P + FS control > H$_2$O$_2$ spray control > H$_2$O$_2$ spray control > SA priming Cd$^{2+}$ > H$_2$O$_2$ priming Cd$^{2+}$ > H$_2$O$_2$ P + FS control > Control Cd$^{2+}$ > SA P + FS Cd$^{2+}$ > SA spray control > H$_2$O$_2$ spray Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$ > H$_2$O$_2$ priming Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > H$_2$O$_2$ P + FS Cd$^{2+}$ > SA spray Cd$^{2+}$ > H$_2$O$_2$ priming Cd$^{2+}$.

Overall data statistically revealed that values for chlorophyll b were not significant ($p > 0.05$); therefore, it was established that, under control, the respective treatments at both the altitude (Qta and Tbt) were at their best, but the priming and foliar application of SA and H$_2$O$_2$ enhanced chlorophyll b content in milk thistle (Figure 4B).

**Carotenoids**

Results obtained for carotenoids of milk thistle, which was grown at two different altitudes (Qta and Tbt) under heavy metal stress of Cd$^{2+}$, reported statistically non-significant results ($p > 0.05$). Data further revealed that the best treatment was SA priming under Cd$^{2+}$ stress at Tbt, while the least carotenoids contents were observed in the SA priming treatment of control of Qta (Figure 4C).

The order of improvement at Qta was observed as SA spray control > H$_2$O$_2$ P + FS control > SA P + FS control > Control Cd$^{2+}$ > H$_2$O$_2$ spray Cd$^{2+}$ > SA spray Cd$^{2+}$ > H$_2$O spray...
control > SA P + FS Cd\(^{+2}\) > H\(_2\)O spray Cd\(^{+2}\) > Control of Control > SA priming Cd\(^{+2}\) > H\(_2\)O P + FS Cd\(^{+2}\) > H\(_2\)O spray control > H\(_2\)O P + FS control > H\(_2\)O P + FS Cd\(^{+2}\) > H\(_2\)O2 priming Cd\(^{+2}\) > H\(_2\)O2 priming control > H\(_2\)O priming control > SA priming control.

While the order at Tbt was recorded as follows: SA priming Cd\(^{+2}\) > H\(_2\)O P + FS control > SA priming control > Control Cd\(^{+2}\) > SA spray control > H\(_2\)O priming control > H\(_2\)O spray control > H\(_2\)O priming Cd\(^{+2}\) > H\(_2\)O2 spray control > H\(_2\)O2 priming Cd\(^{+2}\) > H\(_2\)O2 priming control > H\(_2\)O2 P + FS Cd\(^{+2}\) > H\(_2\)O2 priming control > H\(_2\)O2 P + FS...
control > H$_2$O P + FS Cd$^{+2}$ > H$_2$O spray Cd$^{+2}$ > SA P + FS control > H$_2$O priming Cd$^{+2}$ > H$_2$O spray Cd$^{+2}$ > Control of Control > SA spray Cd$^{+2}$ > SA P + FS Cd$^{+2}$.

Overall data for carotenoids contents revealed that the application of SA both under control and Cd$^{+2}$ conditions of priming and foliar spray highly improved the carotenoids contents at both varying altitudes, i.e., Qta and Tbt. However, under heavy metal concentration (Cd$^{+2}$), the treatments showed a remarkable increase in carotenoids contents, which proves it plays a defensive role in alleviating Cd$^{+2}$ toxicity in milk thistle (Figure 4C).

In a nutshell, considering results, it is proved that the presence of SA and H$_2$O in leaves of milk thistle is highly helpful for accumulation and reduction of the toxic effects of Cd$^{+2}$ (Figures 4A–C).

**Oxidative Damage/Stress Measurement**

**Hydrogen Peroxide (H$_2$O$_2$) Content**

Data recorded for H$_2$O$_2$ of milk thistle both (roots and shoots) under a concentration of 500-μM Cd$^{+2}$ toxicity grown at two different altitudes (Qta and Tbt) in which the root showed statistically significant (p < 0.05) and shoot non-significant (p > 0.05) results (Figures 5A,B). Data for root H$_2$O$_2$ content revealed that highest concentration was observed in Qta and SA P + FS treatment under Cd$^{+2}$ toxicity while the lowest content of H$_2$O$_2$ in root was observed in Control of Control of the same altitude.

The order of improvement in hydrogen peroxide (H$_2$O$_2$) content of root at high-altitude Qta was recorded as follows: SA P + FS Cd$^{+2}$ > H$_2$O$_2$ priming Cd$^{+2}$ > H$_2$O$_2$ P + FS Cd$^{+2}$ > SA spray Cd$^{+2}$ > H$_2$O$_2$ spray Cd$^{+2}$ > SA P + FS control > SA priming Cd$^{+2}$ > H$_2$O$_2$ P + FS control > H$_2$O$_2$ priming control > Control Cd$^{+2}$ > H$_2$O P + FS Cd$^{+2}$ > H$_2$O$_2$ spray control > H$_2$O$_2$ spray Cd$^{+2}$ > SA spray control > Control Cd$^{+2}$ > H$_2$O$_2$ spray control > H$_2$O$_2$ priming Cd$^{+2}$ > H$_2$O spray control > H$_2$O$_2$ priming Cd$^{+2}$ > H$_2$O$_2$ priming control > Control of Control.

While, at low-altitude Tbt, the order of changes reported to be in the following sequence: H$_2$O$_2$ spray Cd$^{+2}$ > SA P + FS Cd$^{+2}$ > H$_2$O P + FS Cd$^{+2}$ > H$_2$O$_2$ P + FS Cd$^{+2}$ > SA P + FS control > H$_2$O$_2$ priming Cd$^{+2}$ > SA priming Cd$^{+2}$ > H$_2$O$_2$ P + FS control > SA spray Cd$^{+2}$ > Control of Cd$^{+2}$ > H$_2$O$_2$ priming Cd$^{+2}$ > H$_2$O spray Cd$^{+2}$ > Control of Control > H$_2$O P + FS control > SA priming control > H$_2$O$_2$ priming control > SA spray control > H$_2$O spray control > H$_2$O$_2$ priming control.

Furthermore, results obtained for shoot H$_2$O$_2$ content revealed that maximum hydrogen peroxide content was observed in H$_2$O P + FS under Cd$^{+2}$ stress at Qta, while minimum content of H$_2$O$_2$ was observed in SA priming under control at Tbt (Figure 5A).

The order of shoot H$_2$O$_2$ content at Qta was recorded as H$_2$O P + FS Cd$^{+2}$ > H$_2$O spray Cd$^{+2}$ > H$_2$O$_2$ priming Cd$^{+2}$ > SA spray Cd$^{+2}$ > SA P + FS control > SA priming Cd$^{+2}$ > H$_2$O$_2$ spray Cd$^{+2}$ > H$_2$O$_2$ priming control > SA priming control > H$_2$O$_2$ priming control > H$_2$O$_2$ P + FS Cd$^{+2}$ > Control of Control > H$_2$O$_2$ P + FS control > H$_2$O P + FS control > Control Cd$^{+2}$ > H$_2$O P + FS control > Control Cd$^{+2}$ > H$_2$O spray control > Control of Control.

In contrast, the order of improvement at the low-altitude Tbt was recorded as follows: H$_2$O$_2$ P + FS Cd$^{+2}$ > H$_2$O$_2$ P + FS Cd$^{+2}$ > H$_2$O P + FS control > H$_2$O spray Cd$^{+2}$ > H$_2$O$_2$ P + FS control > Control Cd$^{+2}$ > SA P + FS control > H$_2$O priming Cd$^{+2}$ > H$_2$O spray Cd$^{+2}$ > H$_2$O spray control > SA spray Cd$^{+2}$ > SA P + FS Cd$^{+2}$ > H$_2$O spray control > SA priming Cd$^{+2}$ > H$_2$O priming control > Control of Control > SA spray control > SA priming control > H$_2$O priming Cd$^{+2}$ > Control of Control > SA spray control > SA priming control > Control of Control.

Considering H$_2$O$_2$ content in the root of milk thistle, it was observed that the priming and foliar spray of signaling molecules, i.e., H$_2$O$_2$ and SA, were most effective in lowering hydrogen peroxide content in roots under Cd$^{+2}$ toxicity. Similar findings were observed for shoots as well, proving the beneficial role of exogenous supplementation of SA and H$_2$O$_2$ in alleviating heavy metal toxicity (Cd$^{+2}$). However, the interactions and trends toward hampering oxidative damage by SA and H$_2$O$_2$ in alleviating Cd$^{+2}$ toxicity vary in roots and shoots (Figures 5A,B).

**Malondialdehyde**

Results obtained for MDA content of roots and shoots of milk thistle under heavy metal toxicity Cd$^{+2}$ (500 μM) at two different altitudes, i.e., Qta and Tbt showed a significant (p < 0.05) difference (Figures 5C,D). Data for root MDA content revealed that the maximum MDA content was observed in H$_2$O$_2$ P + FS under control at Tbt, while the least was observed at Qta under Cd$^{+2}$ toxicity, i.e., H$_2$O$_2$ P + FS.

However, the trend in root MDA content at Qta was observed as H$_2$O$_2$ priming Cd$^{+2}$ > H$_2$O$_2$ P + FS control > SA priming Cd$^{+2}$ > H$_2$O spray control > H$_2$O$_2$ spray control > SA spray control > SA priming Cd$^{+2}$ > Control of Control > H$_2$O spray control > H$_2$O$_2$ spray control > Control of Control.

While, at low altitude (Tbt), the order was recorded as H$_2$O$_2$ P + FS control > SA priming Cd$^{+2}$ > H$_2$O$_2$ P + FS Cd$^{+2}$ > H$_2$O priming Cd$^{+2}$ > H$_2$O P + FS Cd$^{+2}$ > SA spray Cd$^{+2}$ > SA P + FS control > SA priming Cd$^{+2}$ > H$_2$O spray Cd$^{+2}$ > H$_2$O$_2$ priming control > SA priming control > H$_2$O$_2$ priming control > SA spray control > H$_2$O spray control > H$_2$O$_2$ priming control.

Furthermore, data for MDA content in the shoot of milk thistle also revealed significant data (p < 0.05) in which the maximum MDA content was reported in control under Cd$^{+2}$ stress at Tbt; however, the H$_2$O$_2$ P + FS under Cd$^{+2}$ stress at Qta was reported to have a minimum content of MDA (Figure 5C).

The order of changes in MDA content in the shoot at Qta was observed as H$_2$O$_2$ priming Cd$^{+2}$ > H$_2$O priming Cd$^{+2}$ > Control Cd$^{+2}$ > SA priming Cd$^{+2}$ > H$_2$O spray Cd$^{+2}$ > SA priming control > SA P + FS control > SA P + FS Cd$^{+2}$ > SA spray Cd$^{+2}$ > H$_2$O$_2$ P + FS Cd$^{+2}$ > H$_2$O spray control > H$_2$O$_2$ priming control > Control of Control > SA spray control.
Nizar et al. Cadmium Tolerance in Milk Thistle

FIGURE 5 | Oxidative damage parameters; shoot H$_2$O$_2$ (A), root H$_2$O$_2$ (B), shoot MDA (C), root MDA (D) of milk thistle as affected by SA and H$_2$O$_2$ treatment grown at Quetta and Turbat under cadmium stress. The same letters on graphs represent statistically similar effects ($p < 0.05$).
control > H₂O spray Cd⁺² > H₂O spray control > H₂O spray P + FS control > H₂O spray control > Control of Control > H₂O P + FS Cd⁺².

While the trend at Tbt was recorded as follows: Control Cd⁺² > H₂O spraying Cd⁺² > Control of Control > H₂O spraying Cd⁺² > H₂O priming Cd⁺² > SA priming Cd⁺² > SA spray Cd⁺² > H₂O P + FS Cd⁺² > H₂O priming Cd⁺² > SA priming Cd⁺² > SA spray Cd⁺² > SA priming Cd⁺² > SA spray Cd⁺² > SA priming Cd⁺² > SA spray Cd⁺² > SA priming Cd⁺² > SA priming Cd⁺² > H₂O P + FS Cd⁺² > Control of Control > Control Cd⁺² > H₂O P + FS control > H₂O spray control > SA spray control > H₂O priming Cd⁺² > H₂O P + FS control > SA priming control > H₂O P + FS control.

Overall data of MDA content in milk thistle revealed that maximum MDA content in milk thistle had been reported in shoots both in control and Cd⁺² conditions; in contrast, MDA content in root was reported very low. In root, the interactions of SA and H₂O₂ with Cd⁺² were reported to be different. There is a significant difference in both altitudes along with the stress, i.e., Control and Cd⁺². Considering the Cd⁺² toxicity, it is considered that the plant-signaling molecules (i.e., SA and H₂O₂) reported a synergistic effect of these molecules in relation to accumulation and uptake of Cd⁺² toxicity in the roots and shoots, thus enhancing the role of signaling molecules and suppressing the heavy metal toxicity (Figures 5C, D).

Secondary Metabolites

Anthocyanin Content

Results obtained for anthocyanin content (roots and shoots) manifested significant differences in milk thistle grown at two different altitudinal fields, i.e., Qta and Tbt under heavy metal toxicity (500 μM). Data further revealed that, in the roots, the maximum anthocyanin content was determined in H₂O P + FS under Cd⁺² stress at low-altitude Tbt, while the minimum anthocyanins in roots were observed in H₂O priming under Cd⁺² toxicity at the same altitude, showing statistically non-significant (p > 0.05) results (Figure 6B).

However, the trend for root anthocyanin at Qta was observed as SA P + FS Cd⁺² > SA P + FS control > H₂O₂ priming Cd⁺² > SA priming Cd⁺² > H₂O P + FS Cd⁺² > H₂O priming Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS control > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺².

While the order of improvement at Tbt was H₂O P + FS Cd⁺² > SA P + FS Cd⁺² > H₂O spray Cd⁺² > SA P + FS control > SA spray Cd⁺² > H₂O P + FS Cd⁺² > H₂O P + FS control > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺².

Moreover, anthocyanin content in the shoot was the highest in H₂O₂ spray under heavy metal toxicity (Cd⁺²) at Tbt; in contrast, SA P + FS under control remained the lowest treatment observed at Qta. The results for shoot anthocyanin content statistically showed significant (p < 0.05) data in milk thistle (Figure 6A).

On the other hand, the order of changes in attribute of anthocyanin contents in the shoot at Qta was recorded as SA P + FS Cd⁺² > H₂O spray Cd⁺² > H₂O P + FS Cd⁺² > H₂O spray Cd⁺² > SA spray Cd⁺² > H₂O spray Cd⁺² > SA priming Cd⁺² > H₂O spray Cd⁺² > SA priming Cd⁺² > H₂O spray Cd⁺² > SA priming Cd⁺² > H₂O spray Cd⁺² > SA priming Cd⁺² > H₂O P + FS Cd⁺² > Control of Control > Control Cd⁺² > H₂O P + FS control > H₂O P + FS control > SA spray control > H₂O priming Cd⁺² > H₂O P + FS control > SA priming control > H₂O P + FS control > SA priming control > H₂O P + FS control.

At Tbt, the order of improvement was observed as follows: H₂O spray Cd⁺² > H₂O spray priming Cd⁺² > H₂O P + FS Cd⁺² > SA spray Cd⁺² > SA priming Cd⁺² > SA priming Cd⁺² > SA P + FS Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > Control Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O priming Cd⁺² > H₂O P + FS control > H₂O P + FS control > H₂O P + FS control > SA spray control > SA priming control > SA priming control > SA P + FS control.

Considering anthocyanin (i.e., roots and shoots) content at two different altitudes (i.e., Qta and Tbt), it was established that there was a significant difference with the prescribed altitudes. Overall results indicate that anthocyanin content in both roots and shoots showed a small degree of differentiation statistically at Qta and Tbt under heavy metal toxicity (Cd⁺²). Thus, it proved that, along with altitudinal variations, the application of SA and H₂O₂ proved to be the best by reducing the toxic effect and stress of Cd⁺². As compared to roots, there was a maximum increase in shoot anthocyanin content (Figures 6A, B).

Soluble Phenolics Content

Statistical analysis for roots and shoots of soluble phenolics in milk thistle grown at high (Qta) and low (Tbt) altitudes showed statistically significant (p < 0.05) results under application of heavy metal Cd⁺² (500 μM). Considering root soluble phenolics content, it has been observed that the best and effective treatment was SA spray under control at Tbt; however, the less effective treatment was recorded H₂O spray under Cd⁺² stress at the same altitude (Figures 6C, D).

The order of improvement in root phenolics contents in Qta was SA spray control > H₂O₂ priming control > H₂O spray control > H₂O₂ P + FS control > SA priming Cd⁺² > SA P + FS Cd⁺² > H₂O spray Cd⁺² > H₂O spray Cd⁺² > H₂O P + FS spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺² > Control Cd⁺² > SA spray Cd⁺².

While the order of changes at Tbt was SA spray control > H₂O₂ priming Cd⁺² > H₂O spray control > SA priming Cd⁺² > Control of Control > H₂O P + FS control > SA spray Cd⁺² > Control Cd⁺² > H₂O P + FS Cd⁺² > H₂O P + FS diet control > H₂O P + FS diet control > H₂O spray Cd⁺² > H₂O spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺² > H₂O P + FS spray Cd⁺². 

Frontiers in Plant Science | www.frontiersin.org 12 January 2022 | Volume 12 | Article 809183
FIGURE 6 | Secondary metabolites; shoot anthocyanin (A), root anthocyanin (B), shoot soluble phenolics (C), root soluble phenolics (D) shoot tannins (E) root tannins (F) of milk thistle as affected by SA and H2O2 treatment grown at Quetta and Turbat under cadmium stress. The same letters on graphs represent a statistically similar effect ($p < 0.05$).
On the other hand, Soluble phenolics in shoots reported maximum content in H₂O₂ P + FS under heavy metal (Cd²⁺) toxicity at Tbt, while the minimum phenolics content was reported in H₂O priming under Cd²⁺ toxicity at Qta (Figure 6C).

The order for shoot phenolics content at Qta was observed as follows: H₂O₂ spray control > SA priming Cd²⁺ > H₂O P + FS Cd²⁺ > SA P + FS control > H₂O₂ P + FS control > SA spray Cd²⁺ > SA spray control > Control Cd²⁺ > H₂O spray Cd²⁺ > SA P + FS Cd²⁺ > H₂O P + FS control > H₂O spray Cd²⁺ > H₂O priming control > SA priming control > Control Cd²⁺ > H₂O₂ priming control > H₂O₂ priming Cd²⁺ > H₂O P + FS Cd²⁺ > H₂O priming Cd²⁺. However, at Tbt, the order of improvement was recorded as H₂O P + FS Cd²⁺ > H₂O₂ spray Cd²⁺ > SA spray Cd²⁺ > SA P + FS Cd²⁺ > Control of Control > SA priming control > SA spray control > H₂O spray control > SA spray Cd²⁺ > SA P + FS control > H₂O₂ spray control > H₂O spray Cd²⁺ > H₂O₂ priming Cd²⁺ > H₂O priming Cd²⁺ > H₂O P + FS control > H₂O priming Cd²⁺ > Control Cd²⁺. Considering the overall observed results of soluble phenolics contents in both roots and shoots, it has been observed that the maximum phenolic content was observed in shoots as compared to the roots. Data pertaining to this attribute revealed that foliar spray and priming with plant signaling molecules (SA and H₂O₂) played a significant role in reducing the Cd²⁺ toxicity and enhanced the phenolics content in both roots and shoots. Supplementation with SA and H₂O₂ had a stronger effect on the attribute of milk thistle under Cd²⁺ stress as compared to control plants (Figures 6C,D).

Tannins Content

Results obtained for Tannins content in both roots and shoots showed statistically significant results (p < 0.05) in milk thistle grown at two different altitudinal fields (i.e., Qta and Tbt) under Cd²⁺ toxicity (500 μM). Data revealed that, in the roots, the highest content of tannins was recorded in SA spray under Cd²⁺ stress at Tbt, while the lowest tannins content was observed in control treatment of Cd²⁺ at the same altitude (Tbt) (Figures 6E,F).

However, the trend for root tannins contents in Qta was observed as H₂O₂ P + FS Cd²⁺ > H₂O₂ priming Cd²⁺ > SA spray Cd²⁺ > SA P + FS Cd²⁺ > Control Cd²⁺ > SA priming Cd²⁺ > SA spray Cd²⁺ > H₂O₂ spray Cd²⁺ > SA P + FS Cd²⁺ > Control Cd²⁺ > H₂O spray control > Control of Control > SA spray control > H₂O P + FS control > H₂O spray control > Control Cd²⁺ > H₂O₂ P + FS control > SA priming control > SA P + FS control > H₂O priming control > H₂O₂ priming Cd²⁺ > SA priming control > H₂O priming Cd²⁺ > SA spray control > H₂O spray control > SA P + FS control > H₂O spray control > SA P + FS control > H₂O priming Cd²⁺ > SA priming control > H₂O priming Cd²⁺ > SA priming control > H₂O₂ priming Cd²⁺ > Control of Control > H₂O spray control > H₂O priming control > H₂O priming Cd²⁺ > Control Cd²⁺. Moreover, data recorded for shoot tannins in milk thistle also showed significant variations (p < 0.05) under Cd²⁺ toxicity at both altitudes (Qta and Tbt). Furthermore, the obtained results revealed that the maximum tannin contents in shoot were found in H₂O₂ priming under Cd²⁺ toxicity at Qta, while the minimum shoot tannins were observed in control at the same altitude (Figure 6E).

The order of improvement in shoot tannins at Qta was observed as H₂O₂ priming Cd²⁺ > SA priming Cd²⁺ > H₂O spray Cd²⁺ > H₂O P + FS Cd²⁺ > H₂O₂ P + FS Cd²⁺ > SA P + FS Cd²⁺ > H₂O priming Cd²⁺ > SA priming Cd²⁺ > Control Cd²⁺ > H₂O₂ spray Cd²⁺ > H₂O priming control > H₂O spray control > H₂O₂ priming control > H₂O spray control > SA P + FS control > H₂O₂ priming control > H₂O priming control > H₂O priming Cd²⁺ > Control control. While the trend for Tbt was recorded as follows: H₂O P + FS Cd²⁺ > H₂O₂ P + FS Cd²⁺ > SA P + FS Cd²⁺ > H₂O spray Cd²⁺ > H₂O P + FS spray Cd²⁺ > SA spray Cd²⁺ > Control Cd²⁺ > SA spray control > H₂O P + FS control > H₂O spray Cd²⁺ > SA spray control > H₂O P + FS control > Control of Control > H₂O spray control > Control Cd²⁺ > SA spray control > Control Cd²⁺ > SA spray control > Control Cd²⁺ > SA spray control > Control Cd²⁺ > SA spray control > Control Cd²⁺. In a nutshell, the data statistically revealed significant results by applying plant-signaling molecules in alleviating Cd²⁺ toxicity in milk thistle grown under two varying altitudes, i.e., Qta and Tbt. Compared to control field plants at both altitudes, the Cd²⁺ stress plants showed significantly enhanced tannin content in milk thistle, thus indicating the activation of the defensive mechanism by the synthesis of secondary metabolites (Figures 6E,F).

Correlations With Shoot and Root Dry Weights

Drawing correlations of various morpho-physiological attributes with shoot and root dry weights (Table 2) revealed that shoot length positively significantly correlated with the dry weights even under Cd²⁺ stress; however, root length showed a negative non-significant correlation under stress. Considering milk thistle leaf area’s correlation with shoot dry weights revealed that, in Qta, under unstressed conditions, the leaf area positively correlated, while, in Tbt, under cadmium stress, the leaf area positively correlated with the SDW. Photosynthetic pigments, i.e., chlorophyll a, b, and carotenoids showed non-significant correlations except for Chl a at Qta in control milk thistle plants that showed significant positive correlations. Secondary metabolites showed non-significant correlations with the shoot and root dry weights under both control and Cd²⁺ stress except for shoot soluble phenolics and root tannin showing significant negative correlation under control conditions and Cd²⁺ stressed plants, respectively, of the Tbt area.
TABLE 2 | Correlation of changes in various morpho-physiological attributes of milk thistle with shoot and root dry weights grown at Quetta and Turbat under cadmium stress (n = 10).

| Parameter          | Stress  | Area          |

DISCUSSION

The results of this study on milk thistle illustrate the significant role of plant-signaling molecules SA and H₂O₂ in alleviating Cd²⁺ toxicity at two varying altitudes of Balochistan (Qta and Tbt), Pakistan. However, the priming and foliar spray of SA and H₂O₂ enhanced the germination, morpho-physiological effectiveness at both altitudes, thus thereby ameliorating the toxic effect of Cd²⁺ in milk thistle. Cd²⁺ is widely recognized as a toxic heavy metal in soil by destabilizing the integrity of membrane and status of nutrients; that inhibits biosynthesis of chlorophyll that resulted in the reduction in plant growth and development (Lu et al., 2018; Majumdar et al., 2020). Considering the growth attributes of the present study, it was observed that roots, shoot length, and weights decreased under Cd²⁺ toxicity; however, the supplementation of SA and H₂O₂ helps the milk thistle plants to alleviate the toxic impacts in single or combinational treatments at both experimental sites. Khatatipour et al. (2011) reported the various Cd²⁺ concentrations significantly reduce root length in milk thistle. The decline in root length was more pronounced because of the Cd²⁺ treatment as compared to shoot length. The toxicity of Cd²⁺ was previously reported in different plant species and groups (Kaur et al., 2017; Lu et al., 2018; Kaya et al., 2019; Majumdar et al., 2020). The attributes for growth in Brassica juncea, such as shoot/root length, dry and fresh weight, along with the leaf area, decreased by the application of Cd²⁺ (Faraz et al., 2020). However, the findings of Migahid et al.’s (2019) research suggested that priming of seeds with H₂O₂ increased the leaf area, dry weight of roots and shoots, and root and shoot fresh weight of milk thistle (Gaertn) in comparison with control (Wahid et al., 2007). Furthermore, in the present study, it has been reported that Cd²⁺ toxicity decreased the leaf area at high altitude (Qta), but by the priming and foliar application of plant-signaling molecules (i.e., SA and H₂O₂), the morphological parameters (i.e., root/shoot length, the number of leaves, shoot and root fresh weight) increased and also alleviated the toxic effects of heavy metal cadmium (Figures 2A–C, 3A,D).

The application of Cd²⁺ concentration reduces the rate of photosynthesis by targeting various electron transport chain components in carboxylation reactions along with PSII (Shah et al., 2020). Study, conducted by Guo et al. (2019) also reported a decrease in contents of chlorophyll and fluorescence under Cd²⁺ toxicity. In this study, milk thistle plants treated with priming and foliar spray of SA and H₂O₂ have a propounding effect on alleviating the toxicity of Cd²⁺ on the photosynthetic pigments (Figures 4A–C). The carotenoid contents in plants were reduced because of high cadmium Cd²⁺ (Cai et al., 2011), while our findings showed non-significant (p > 0.05) results under both control and Cd²⁺ conditions. Carotenoid contents are enhanced due to plant-signaling molecules (SA and H₂O₂) at high- (Qta) and low-altitude Tbt (Figure 4C). Carotenoids are the potent antioxidants that serve as reactive oxygen species (ROS) against disruption of photo-oxidative in photosystems (Zahra et al., 2021d), thus suggesting the putative role of SA and H₂O₂ in improving plant defense mechanisms.

MDA is considered the main product for peroxidation of the lipid membrane. Contents of MDA reflect the damage to structures of cell membranes (Parida and Jha, 2010). While, under Cd²⁺ toxicity, high-level MDA accumulation is reported to enhance O₂⁻ and H₂O₂ (Wang et al., 2013a; Xu et al., 2014). Furthermore, Krantev et al. (2008) reported that seeds of maize were presoaked with 500 mM SA before applying the Cd²⁺ has a protective effect by diminishing MDA accumulation, which is involved in the protection against oxidative damage. Wang et al. (2013a,b) and Bai et al. (2015) also reported pretreatment of SA under cadmium stress-reduced MDA contents. In the present study, it has been reported that MDA content enhanced in roots of milk thistle under Cd²⁺ stress (Figure 5D). Popova et al. (2008) reported that Cd²⁺ was accumulated in roots of the plants because it is the basic organ that was exposed to heavy metals in soil and translocated to shoots as well. Cd²⁺ stress was reported to cause lipid peroxidation in roots of pea seedlings with increasing levels of H₂O₂ (Podazza et al., 2012). The outcome of the report was further shown in the study of El Dakak and Hassan (2020) that H₂O₂ was not significantly accumulated (p > 0.05); hence, our findings support the same findings that H₂O₂ content in shoots showed non-significant results in milk thistle under Cd²⁺ stress (Figure 5A). Song et al. (2014) reported enhancing activities of antioxidative enzymes (i.e., SOD and POD) along with some other enzymatic antioxidants such as CAT and APX decreased by the exposure of Cd²⁺ toxicity. Liu et al. (2010) reported that Cd²⁺-generated oxidative damage interacts with antioxidant defense system. While the increasing activity of SOD and POD
indicated detoxifying of ROS (Ferreira et al., 2002; Krantev et al., 2008). Furthermore, POD activated by Cd$^{+2}$ at a minimum level is responsible for the removal of H$_2$O$_2$, which insignificantly ($p > 0.05$) increased.

Plant secondary metabolites play a key role in defense against environmental stresses (Yang et al., 2018). A slow process was observed due to secondary metabolites accumulation during the stress conditions in lemongrass, which reported greater accumulation in soluble phenolics, flavonoids, and anthocyanin, while the accumulation of tannins content was minimum both in the shoots and roots (Shaukat et al., 2020) after exposure to different altitudes. Basically, tannins are of two types (i.e., condensed and hydrolysable). The condensed tannins are physiologically less significant due to being much complex, not soluble, but hydrolysable tannins played a significant role in growth attributes along with development under adverse conditions (Tiku, 2020). Such compounds, apart from tannin, are mainly found in the soluble phase, which increases in the concentration of secondary metabolites under adverse environmental conditions that are known (Tiku, 2020). In the present study, it has been observed that accumulation of tannin content in roots and shoots of milk thistle at both altitudes (i.e., Qta and Tbt) enhanced under Cd$^{+2}$ stress. However, at Tbt, the tannins contents in roots were comparatively less than in Qta milk thistle plants, thus indicating environmental regime variation impact (Figures 6E,F).

Phenolics are donors of electrons that could mitigate the oxidative stress effect, which is an ultimate substrate for antioxidant enzymes, i.e., peroxidases (Posmyk et al., 2009). Migahid et al. (2019) reported that the total phenolic contents in milk thistle did not change under H$_2$O$_2$. However, our findings in the present study suggest that phenolics contents in the roots decrease significantly in control and Cd$^{+2}$ conditions at both altitudes (i.e., Qta and Tbt), while phenolics contents in shoots significantly ($p < 0.05$) increased to a high level as compared to root phenolics, while, under Cd$^{+2}$ stress, the respective treatments applied with a concentration of SA and H$_2$O$_2$ showed significant results (Figures 6C,D). Chaman et al. (2003) reported that SA increases the phenylalanine ammonia-lyase activity that is an essential enzyme being involved in phenolics compounds biosynthesis in the early stages. Zahra et al. (2021d) reported that, in milk thistle, it was purused that the alkaloid and anthocyanin contents enhanced under stress in comparison with control. It was also reported from the study of Khan et al. (2019) that foliar application of SA increased anthocyanin contents in seedlings of rice subjected to abiotic stress. The same tendency was observed in the present study, that anthocyanin contents in shoot significantly ($p < 0.05$) increased while, in roots, a non-significant ($p > 0.05$) increased under Cd$^{+2}$ toxicity (Figures 6A,B). However, under control conditions, the contents of anthocyanin remain suppressed at both the altitudinal fields Qta and Tbt (Figures 6A,B), thus providing the evidence that the secondary metabolite increases and work as defense system under stressful environments.

**CONCLUSION**

The toxicity of heavy metal (Cd$^{+2}$) hampered the morphological and physiological attributes of milk thistle grown at two different altitudes. Data revealed that, under Cd$^{+2}$ toxicity, morphophysiological attributes were hampered. However, priming and foliar treatment of plant-signaling molecules SA and H$_2$O$_2$ showed a positive impact on alleviating the toxic effect of Cd$^{+2}$. The secondary metabolites showed improved tolerance to Cd$^{+2}$ concentration supported the growth and development of milk thistle at both altitudes by modulating Cd$^{+2}$-induced changes, especially with the application of SA and H$_2$O$_2$. Milk thistle being a weed plant grown in areas, which are mostly heavy metal affected due to industrially released chemicals, mining, and cadmium present in soil; it would be very beneficial to grow these plants, which can tolerate heavy metal stress. The present research is thus helpful to conduct comparative studies of medicinal plants grown under varying altitudes and under cadmium/heavy metal stress. The study motivates to unveil the genes involved in ameliorating the heavy metal toxicity in the same plant across the altitudinal gradient as no such literature has yet been reported.

**DATA AVAILABILITY STATEMENT**

The original contributions presented in the study are included in the articlesupplementary material, further inquiries can be directed to the corresponding authors.

**AUTHOR CONTRIBUTIONS**

MN and KS conceived and designed the research. MN, KS, and AS performed the experiment and wrote the initial draft of the manuscript. AR, NZ, and MBH assisted with the analysis, revised subsequent versions of the manuscript, and provided the technical guidance. AR, KS, QA, HMA, and MHS proofread and edited the final version. All authors have read and agreed to the published version of the manuscript.

**FUNDING**

The publication of this work was supported by the Researchers Supporting Project Number (RSP-2021/123), King Saud University, Riyadh, Saudi Arabia.

**ACKNOWLEDGMENTS**

We are thankful to all members of Department of Botany, University of Balochistan, Quetta, Pakistan, for providing research environment and support to conduct this study. Furthermore, we would like to extend their sincere appreciation to the Researchers Supporting Project No. RSP-2021/123, King Saud University, Riyadh, Saudi Arabia.
